2. That it is impossible to enucleate the prostate out of the capsule; it can only be dissected out.

3. That the prostatic capsule of the surgeon consists of compressed prostatic tissue.

4. That hypertrophy takes place only in the central lobe.

5. That enucleation of the hypertrophied prostate occurs inside of a circular layer of compressed prostatic tissue, detached from the central part of the gland.

6. That this part of the gland is interwoven with the proximal end of the urethra.

7. That malignancy of the prostate is observed from earliest childhood until old age.

The etiology of hypertrophied prostate is unknown. The author quotes Wilson and McGrath, who have done extensive work along this line. These men state, "No hypothesis has yet been advanced which will adequately explain the cause." Freyer, after studying one thousand cases of complete enucleation states, "I have to confess that I have still no insight into the origin of this disease."

Conditions requiring prostatectomy are:

1. When there are three to fifteen ounces of residual urine.

2. Extreme over-distension and dribbling.

3. Retention from time to time.

4. Ability to void some urine without use of catheter.

5. Entire dependence on catheter.

6. Complete retention and beginning infection.

Symptoms of prostatism: Primary symptoms are: (1) Frequency of micturition, becoming more difficult and prolonged. (2) The stream starts slowly and sometimes dribbles — followed by a sense of fullness, burning pain and distress. (3) These symptoms gradually become more and more pronounced and partial or absolute retention may or may not intervene.

Secondary symptoms are insomnia, loss of appetite, strength, and weight.

The proper anti-operative treatment is very essential, in regard to the proper action of the skin, kidneys and bowels. In septic cases perineal or suprapubic drainage should be established as a preliminary measure in treatment.

In the choice of an operation and the technique used, one should deliberately weigh the evidence presented, and, keeping in mind the element of safety, choose the operation that will promise the most favorable result in the individual case. With the present knowledge of the anatomy and pathology of the prostate, the suprapubic method should be the operation of choice unless there are strong contra-indications.

The author holds that the advantages to be gained are:

1. It provides absolute control from the time the urine is first voided through the urethra.

2. It enables one thoroughly to explore the bladder.

3. It is less likely to be attended with painful complications (such as inflammation in epididymis or testicle, or wound of the rectum). The disadvantage is that the suprapubic wound usually requires a longer time to heal. Freyer's method of complete enucleation is the one of choice.

The perineal operation should be reserved for cases presenting: (1) Hard fibrous prostate. (2) When the gland is situated well down toward the perineum. (3) If condition is complicated by presence of stone. (4) In fibrous or malignant cases when the gland must be dissected out. The method of Young is the one of choice.

The author concludes by saying, "Prostatectomy is not an operation to be attempted by an inexperienced surgeon."

H. A. MOORE.

MISCELLANEOUS

Legueu, Papin, and Maingot: Radiographic Examination of the Urinary Tract (Exploration radiographique de l'appareil urinaire). Paris: Gittler, 1913. By Journal de Chirurgie.

Radiography can give invaluable information regarding the anatomy of the urinary apparatus. When a sufficiently delicate technique is used, the shadow of the kidney is seen in three-fourths of the cases and not only the position and relations but

also the shape and size of the organ can be determined.

The renal blood vessels can be well studied by radiography after their injection with opaque material. The authors have thus demonstrated the presence of end-arteries and the venous connections in the kidney.

By injecting into the urinary tract 10 per cent collargol it is possible to obtain good pictures of the hilum, calices, ureters and of the changes in shape of the bladder.

By simple radiography or with the aid of opaque catheters or collargol, the anomalies of shadow and disorders of the kidneys and ureters can be accounted for. There is no other method of demonstrating these things as accurately as does the radiograph. The same is the case in renal retention, to which one of the chapters in this most excellent and original work is devoted.

Search for calculi in the urinary apparatus is still the commonest cause for urinary radiology, as it is best known to the physicians at large. Now with good technique only 2 or 3 per cent of stones in the kidney or ureter are missed unless the stones are very small or the patient very stout, unless the patient moves, or the stone is made of uric acid. The existence of diverse shadows often makes the absolute diagnosis of uretral calculi very difficult to those who have not had considerable experience. The problem is generally less difficult to solve for stones and foreign bodies in the bladder.

The study of movable or tuberculous kidneys or of renal tumors is often facilitated by the X-ray, as the numerous negatives show.

Finally, the possibility in certain cases of studying the condition of the prostate and the caliber of the urethra completes the review of the uses of radiography in this connection. R. LEDOUX-LEBARD.

Marion: Significance of Hiccough Following Operation on the Urinary Tract (De la signification du hoquet post-opérative chez les urinaires). *J. d'Urol.*, 1913, iii, 580. By *Journal de Chirurgie*.

Hiccough similar to that observed in peritonitis, or in certain hysterical patients, occurs not infrequently after operation on the urinary tract. It lasts for hours, may intermit for a variable time, recurs without apparent cause and so goes on, not infrequently ending in death after several days, during which time the patient has become progressively enfeebled and torpid.

Marion believes that this symptom is in the greater majority of cases a uræmic manifestation, an evidence of "azotemia." Four patients who presented this symptom showed a coincident marked increase in the quantity of urea in the blood (.8 gr. before operation, 1.2 during the hiccough: .83 before, 4.28 after, etc.). These cases, supposedly, under the influence of chloroform, or of a post-operative infection, have suffered a "touch of nephritis." The treatment of choice is, therefore, the use of a non-nitrogenous diet and of sedatives, of which latter ether and valeronal appear to be especially useful. J. TANTON.

Bachmann: Venereal Prophylaxis; Why It Sometimes Fails. *J. Am. M. Ass.*, 1913, lx, 1610. By Surg., Gynec. & Obst.

The author reviews the work of Russell and Nichols of the U. S. Army to demonstrate the value of calomel ointment and other antiseptics as a prophylactic against gonorrhœa. Their experiments were made in cases of acute gonorrhœa. The ointment was injected into the urethra and retained fifteen minutes then washed out by urination after which the urethral secretion expressed from the meatus was cultured upon ascites agar and examined with Gram's stain. Two series of eight cases each were studied. In the first 25 per cent calomel with phenol and camphor in lanolin and lard was used. It proved effective in seven of the eight cases. In the second series 30 per cent calomel in lanolin and 3 per cent phenol in lanolin were used with failure in all cases.

Bachmann in nine exposures in different men to an infected woman used the navy ointment (33⅓ per cent calomel, 1 per cent tricresol in benzoinated lard) and obtained negative results in all. Two control cases, who did not use the ointment, were infected. With this ointment the author then repeated Russell and Nichols' work in two series of sixteen cases each, making cultures from platinum loop scrapings in the first and from expressed secretion from the meatus in the second. Of the first series seven were positive, and nine negative, and of the second, nine were positive and seven negative. Tubes of ointment bought in the open market proved failures in all of a third series of six cases.

The author calls attention to variations in the ingredients and their proportions making up the ointments and also the difference in technique of their application as causes for failures. H. G. HAMER.

SURGERY OF THE EYE AND EAR

EYE

Brown: The Relation of Accessory Cavity Diseases to the Eye and the Orbit. *Ohio St. M. J.*, 1913, ix, 207. By Surg., Gynec. & Obst.

The close anatomical relationship of the eye and its appendages to the nose must be granted. The relationship of the blood supply is also close. In sinusitis the following symptoms are often noted: headache, variously located but more or less constant; infra-orbital, supra-orbital neuralgia; asthenopia, smarting and burning of eyes and eyelids, or acute ocular fatigue on close work. Hyperæmia of the conjunctiva, orbital cellulitis, abscess, exophthalmos, œdema of lids, optic neuritis and panophthalmitis are frequently associated with sinus disease. Sixty per cent of the cases of orbital inflammation are of known nasal origin. Then follows a report of seven cases with orbital or ocular disease, improvement or cure following treatment of the causative disease in every case. The article is illustrated by eight photographs of anatomical specimens demonstrating the relations very clearly.

In the discussion, STUCKY brought out the influence of internal toxæmias on the nasal structures, explaining that an intestinal auto-intoxication may cause an occluding œdema and that under these conditions the retained secretion becomes purulent. WOODS brought out the importance of more careful nasal examination in eye conditions as spoken of above. FISH emphasized the importance of the X-ray in sinus diagnosis. MURPHY (Cincinnati) spoke of the frequent complication of sinus disease in acute infectious disease. EARLE B. FOWLER.

Lang: The Influence of Chronic Sepsis upon Eye Disease. *Lancet*, Lond., 1913, clxxxiv, 1368. By Surg., Gynec. & Obst.

Lang has been credited as first to recognize the connection between pyorrhœa and the inflammation of the iris and in this article sums up and illustrates his observations. The nature of the poison he has not determined.

Of his series, two hundred and fifteen were attributed to chronic sepsis, one hundred and sixty-eight to all other recognized causes. Of two hundred and fifteen toxic cases one hundred and thirty-nine were due to pyrrhœa, others to sinus inflammation, alimentary toxæmia and urethritis.

Though chronic sepsis may cause inflammation in any portion of the eye the uveal tract is shown to be most frequently involved. The ten cases cited illustrate the rapid recovery that follows removal of the causative factor. EARLE B. FOWLER.

Dwyer: The Use of Vaccines in Eye Infections. *Arch. Ophth.*, 1913, xlii, 227.

By Surg., Gynec. & Obst.

From his observations of 300 cases Dwyer states that vaccines, properly administered, are agents which have no equal in certain cases of eye infection.

Of twenty-seven cases of hordeola, in all of which some strain of staphylococcus was isolated and an autogenous vaccine given, twenty-four have been entirely free from the attacks since the treatment. The dosage was 100 million increasing to 1,000 million, given five days apart and seven or eight doses in all, two after the condition had cleared up. A general improvement in health was noted in most of the cases after the first injection. Further, twelve infections with the tubercle bacillus are reported diagnosed clinically and by the tuberculin reactions. Of these five phlyctenular conjunctivitis and keratitis cleared and have not recurred. One case of iritis, three of keratitis, one of choroiditis and two of episcleritis all responded rapidly to tuberculin injections.

The gonococcus vaccine was used in two cases of iritis with rapid clearing, and in four cases of conjunctivitis the author believes the course was much shortened by the very large doses given. A pneumococcic ulcer of the cornea responded very satisfactorily in three cases. In staphylococcic dacryocystitis (3) and conjunctivitis (3) the results were gratifying. Two cases of Morax-Axenfeld gave surprising results under autovaccine treatment. A two-page digest of immunity and serum-therapy follows. The author favors autovaccine as compared with stock products where practical.

EARLE B. FOWLER.

Vail: A Study of Some Forms of Congenital Cataract, with Special Reference to Their Clinical Significance. *Lancet-Clin.*, 1913, cix, 528. By Surg., Gynec. & Obst.

Vail describes the embryonic development of the lens and discusses the different forms of congenital cataract, following the teachings of Collins and Mayou. In the disk-shaped or "anuclear" cataract he believes it is a mistake to do the needling operation. Col. Smith would extract such a cataract with iris forceps through a small corneal incision, after having made a good-sized iridectomy.

In educated classes an iridectomy may be performed early and another operation done for the cataract when the lens becomes fully cataractous. In cases of cataract with considerable opacification of the lens, it is generally a mistake to consider needling, as the opacities are insoluble and are irritating when liberated. C. G. DARLING.

Simpson: The Intra-Capsular Operation for Cataract after the Method of Professor Stancleanu. *Ophthalm. Rec.*, 1913, xxii, 241.
By Surg., Gynec. & Obst.

Simpson describes the intra-capsular operation for cataract as done by Stancleanu. The upper lid is held with a double hood retractor, well away from the eye. The operation is done in a dark room by electric light. The incision in the cornea is a trifle larger than the ordinary. An iridectomy is made. The anterior capsule of the lense is then grasped with a special forceps without teeth. The closed forceps is passed sideways into the anterior chamber; when in the pupillary area it is turned perpendicular to the surface of the lens and by a slight pressure backwards, made to bite the capsule.

The zonular fibers are ruptured by side-to-side and up-and-down movements. When the lens is loose, the forceps is opened and removed. If the capsule is torn loose, the operation goes on in the usual way. After the lens is loose continuous pressure is made with a spoon over the cornea, slightly below the center, with slight counter-pressure above the cornea. As the lens in its capsule comes through the incision, it is followed with the spoon from below.

C. G. DARLING.

Campbell: Five Cases of Hereditary Cataract. *J. Ophthalm., Otol. & Laryngol.*, 1913, xix, 144.
By Surg., Gynec. & Obst.

Campbell reports operating five cases of hereditary cataract occurring in three persons with a family history of seven or more in the same family, all developing cataract between the ages of twenty-five and twenty-nine, in eyes previously normal.

In the first case seen by Campbell, cataract developed at twenty-eight in one eye and at thirty-three in the other. Case 2, the brother of Case 1, developed cataract at the age of twenty-six in both eyes. Case 3, the sister of Cases 1 and 2, had at the age of twenty-five, an operation for cataract on one eye. Campbell operated the other eye one and a half years later. The father of these patients had been operated for cataract when thirty years of age. The father's sister and a cousin also had cataract at an early age.

C. G. DARLING.

Jennings: The Removal of Senile Cataract Before Maturity. *Med. Herald*, 1913, xxxii, 97.
By Surg., Gynec. & Obst.

Jennings advises the removal of cataract when immature, if vision of both eyes is low.

He makes a corneal incision without conjunctival flap, uses capsule forceps for opening the capsule and washes out the cortical matter with salt solution, using a glass tip syringe introduced well down into the lenticular space.

C. G. DARLING.

Meding: Another View of the Extraction in the Capsule Cataract Operation. *Arch. Ophthalm.*, 1913, xlii, 241.
By Surg., Gynec. & Obst.

Meding gives the reasons for the study of the Indian cataract operation under Col. Smith as these:

The crying need for relief from immature cataract; dissatisfaction with the cataract operation he was using because of the capsule remnant left behind, and unsatisfactory cosmetic results.

With a tribute to Col. Smith, Meding tells of the operation and his experience with it. The main and apparently forbidding difficulty of the operation is the factor of pressure. The pressure necessary to express the lens in its capsule demands "thinking fingers." As taught at Auritsar, the pressure is positive, controlled and safe; under good tuition it can be learned. A competent assistant is necessary. Results are startling. The author found what he sought: one operation, a clear pupil, a vision to enable men to earn their living at their usual vocation; easiest in the immature, most difficult in the hypermature.

The field is prepared by douching with 1-2000 bichloride and without rubbing, squeezing or evert-ing.

EARLE B. FOWLER.

Stähli: Contribution to the Pathology of Hæmorrhagic Glaucoma. *Arch. Ophthalm.*, 1913, xlii, 248.
By Surg., Gynec. & Obst.

Stähli gives a detailed microscopic description of three additional cases of hæmorrhagic glaucoma and furnishes further data to corroborate the findings of others, namely, that marked and typical changes are present in the central vessels. Although serial cross-sections of the optic nerve were made, the pathological changes are ingeniously elucidated by two composite figures which picture axial sections of the central artery. The greatest changes were found in the intima, but not located in the region of the lamina cribrosa, where, as a rule, they have been described. In all three cases more or less sclerosis was found in the central arteries and veins. The greatest change consisted of a true hydrops of the intima cells, which constituted the principal cause for the endarteritic thickening, and stress is laid on this œdematous condition because acute and transitory occlusion of the vessels may result from it. The fact that the endothelium was everywhere intact furnishes proof that thrombosis had not occurred. Vascular changes were also found in the choroid, ciliary body, and iris. These changes have led to the recognition of hæmorrhagic glaucoma as a separate disease from glaucoma.

FRANCIS LANE.

Hallett: Glaucomatous Tension Relieved by Anterior Sclerotomy. *J. Ophthalm., Otol. & Laryngol.*, 1913, xix, 178.
By Surg., Gynec. & Obst.

Hallett, with the idea of making an iridectomy more favorable, did an anterior sclerotomy with a split keratome as a preliminary effort to reduce high tension in a case of typical acute glaucoma. Postponing the iridectomy for one week, it was found that normal tension had been restored and that the vision had improved from fingers at six feet to 10/200. After four more weeks 20/100 was recorded and the patient was enabled to resume his former occupation.

The author kept the case under observation for a period of twenty-one months, and, although the field was much contracted and deep glaucomatous cupping was present, the vision remained the same and the glaucoma was apparently arrested.

FRANCIS LANE.

Hird: A Case of Enlargement of the Eye-Ball.

Ophth. Rev., 1913, xxxii, 137.

By Surg., Gynec. & Obst.

The patient was a boy aged eleven, who had the condition since infancy. Examination revealed the following: left face and ear appeared to be a little larger than the right, but on taking careful measurements in all directions only a slight enlargement of the left ear could be made out with certainty. The left palpebral fissure was a little larger than the right and this in spite of the fact that, if anything, there was slight enophthalmus. When the globes themselves were compared the difference was very evident; the left eye-ball appeared much larger than the right. The corneal diameters were: left vertical 13 mm. and the horizontal 14 mm. The pupil reactions were normal, but the left was larger (4 mm. diam.) than the right (3 mm. diam.), fixing a distant object in ordinary daylight. There was no tremulousness of the iris in the left eye and when the pupil was dilated the edge of the lens could not be seen and therefore did not appear to be small in comparison with the rest of the eye. The left anterior chamber was distinctly deeper than the right. Intra-ocular tension was quite normal in both eyes. There was no evidence of stretching or thinning of the sclerotic coat in the left eye. The fundi were quite normal, with not the slightest sign of any pathological cupping. The physiological cup was normally present in the left eye.

The child was myopic, and, as there was some ciliary spasm, he was put under atropin for a few weeks. It had no effect on the tension in the left eye, which remained at normal with a widely dilated pupil. After nine months the conditions were unchanged. Fuchs states in his textbook that infantile glaucoma may come to a standstill, and, of course, this case may be an abortive one. The author thinks it is a simple hypertrophy of the globe.

EARLE B. FOWLER.

Pooley and Wilkinson: Blindness of Left Eye Due to Pressure of Distended Maxillary Antrum.

Ophth. Rev., 1913, xxxii, 130.

By Surg., Gynec. & Obst.

The case reported is that of a woman 30 years of age who gave a history of left blindness coming on in twenty-four hours with no other symptoms except periodic headaches. In examining the eye there was no perception of light, pupil inactive except to light thrown in opposite eye, media clear and fundus normal. Puncture of left antrum was followed by an escape of straw-colored fluid. Operation through the canine fossa with removal of a polypoid growth and an opening for permanent drainage into the

nose was done at once. Vision improved rapidly up to normal about the twelfth day.

The case is summed up as one of pressure on the optic nerve by displacement, upward, of the antrum from pressure of the cyst within. This is a rare condition and no report of a similar case was found by the authors.

EARLE B. FOWLER.

McReynolds: Some Impressions of the Oxford Ophthalmological Congress and the Ophthalmological Section of the British Medical Association at Birmingham.

Tex. St. J. Med., 1913, viii, 332.

By Surg., Gynec. & Obst.

Three fourths of the combined sessions was devoted to the consideration of subjects introduced by men connected with the provincial governments.

McReynolds says, in considering British ophthalmology, that a broader view of the field must be taken since Col. Smith has performed more than 25,000 cataract extractions and Major Elliott has done about 400 trephining operations for glaucoma.

British ophthalmologists generally are not yet ready to adopt the Smith operation, the consensus of opinion being distinctly in favor of the combined extraction whether intracapsular or not. There was strong endorsement of MacEwen's methods of irrigating the anterior chamber, and vigorous opposition to the early performance of a secondary operation on the capsule.

In regard to glaucoma, the general opinion prevailed that correct iridectomy was reasonably effective in acute glaucoma and that experience indicated that the methods of Elliott and Herbert presented marked advantage for the chronic types.

C. G. DARLING.

EAR

Wells: A Case of Mastoid Abscess without Otorrhœa.

Va. M. Semi-Month., 1913, xviv, 56.

By Surg., Gynec. & Obst.

The author reports an interesting case operated on for mastoiditis in which otorrhœa was absent. The patient presented a diffuse œdema over the mastoid and some tenderness on deep pressure. Otoscopic examination showed a thick, red, but perfectly intact, drum membrane. His condition was normal otherwise, except for the loss of weight.

After the mastoid was opened, the hard bone was found softened and necrotic, with pus formation in places. It extended to the mastoid apophysis, upwards including the zygomatic cells, backward to the ridge of the lateral sinus, and forward nearly to the posterior wall of the meatus. The wound healed rapidly and completely and the patient showed improvement in general.

WALTER H. THEOBOLD.

Voorhees: Serous and Suppurative Labyrinthitis; Differential Diagnosis.

Boston M. & S. J., 1913, clxviii, 716.

By Surg., Gynec. & Obst.

Operation procedure in serous labyrinthitis results in loss of hearing, whereas failure to operate

in a case of suppurative labyrinthitis endangers the life of the patient, hence the importance of this differentiation. Two forms of the serous type have to be considered: the first, an accompaniment or result of some destructive process on the inner tympanic wall, known as diffuse serous secondary labyrinthitis; the second, a sudden non-suppurative inflammation due to disturbance of the vascular system of the middle and internal ear, often occurring three or four days after a radical operation. This is the diffuse serous induced type. The second can only be determined by careful and exhaustive functional tests. So long as there is a remnant of labyrinthic function, diffuse suppurative disease is not present. The suppurative type is divided into the diffuse latent and manifest forms.

The author comes to the following conclusions: In general, if the slightest remnant of function is still present the labyrinth should not be disturbed, i.e., there should be no shaking up, no probing, no meddling of any kind, and absolute rest in bed should be enjoined. If the labyrinth is completely out of commission, the history of the case must be carefully weighed and as accurate a diagnosis as possible arrived at. One may wait a week or ten days, and if there is the slightest peioration of the symptoms a labyrinthine operation should then be performed.

DIFFERENTIAL TABLE MODIFIED FROM RUTTIN

Type of Diseases	Anamnesis (History)	Present Symptoms	Nystagmus	Hearing Caloric Reaction	Turning Reaction	Fistula Test
Diffuse serous secondary labyrinthitis.	Dizziness some time ago	+	To sound side — +	+	+	+
Diffuse suppurative manifest labyrinthitis.	Dizziness present or absent	+	To sound side —	—	—	—
Diffuse suppurative latent labyrinthitis	Dizziness some time ago	—	Absent or to both sides	—	— + if compensated	—

EARLE B. FOWLER.

Hautant: Indications for and Technique of Trepanation of the Labyrinth (Indications et technique de la trépanation labyrinthique). *Rev. hebdom. de laryngol., d'otol. et de rhinol.*, 1913, xxxiv, 609. By Journal de Chirurgie.

Hautant deals only with trepanation of the labyrinth in suppurative labyrinthitis. In partial labyrinthitis (simple fistula, circumscribed labyrinthitis, and partial diffuse labyrinthitis) it is useless to trephine. Moreover, the operation is contra-indicated if any of the sense of hearing remains.

In complete acute labyrinthitis Alexander advises waiting for spontaneous recovery and operating only in case meningeal symptoms appeared. Ruttin,

on the other hand, counsels immediate intervention. The author divides complete acute labyrinthitis into two forms: one benign and the other dangerous.

Under the benign form he classes: (1) Post-operative labyrinthitis resulting from trauma to the horizontal semicircular canal; (2) acute labyrinthitis arising during the course of simple acute otitis; (3) labyrinthitis complicating acute mastoiditis; (4) tuberculous and scarlatinal labyrinthitis.

Under the dangerous form he classes: (1) Post-operative labyrinthitis following injury to the fenestrum ovale; (2) complete acute labyrinthitis developing during an exacerbation of a chronic suppurative otitis media and accompanied by signs of marked vestibular reaction lasting more than fifteen days.

In general, chronic labyrinthitis does not require operation. Trepanation of the labyrinth in these cases is done only when there are persistent symptoms of vestibular irritation (vertigo, spontaneous nystagmus and disturbance of equilibrium) or when a facial palsy or the presence of a sequestrum or of a zone of osteitis is diagnosed.

The appearance of meningeal or cerebellar symptoms is indicative of complicated labyrinthitis. If this occurs during the course of an acute otitis or mastoiditis one may limit operative procedure to paracentesis of the tympanum or to trepanation of the mastoid, since in these cases we have usually to deal with a simple diffuse meningeal irritation; but on the other hand, when complicated labyrinthitis appears during the course of a chronic otorrhœa the labyrinth must be trephined. The operation advised by the author has two aims: (1) To open and drain the vestibule which is the center of the infection by an anterior opening which prevents the propagation of the infection to the internal auditory canal (ante-facial trepanation). (2) To guarantee the isolation of the vestibule from the posterior cerebellar fossa by a posterior contra-opening made in the depths of an intersinuso-facial incision.

The anterior opening of the vestibule consists in uniting the fenestrum rotundum and the fenestrum ovale. Thus the lower and anterior portion of the vestibule, and the origin of the first spiral of the cochlea are laid bare. The retro-facial contra-opening is situated on a horizontal line which passes through the posterior pole of the fenestrum ovale and extends 5 millimeters posterior to this pole. This gives access to the horizontal canal and by following the posterior branch of this canal, one arrives directly at the vestibule.

Trepanation of the labyrinth has an operative mortality of 4½ per cent. The author claims that the results obtained have proved that it constitutes a real progress in the treatment of suppuration in this region.

GEORGES LAURENS.

SURGERY OF THE NOSE, THROAT, AND MOUTH

Lawner: Tumors in the Neighborhood of the Ostium Pharyngeum Tubæ (Geschwülste in der Gegend des ostium pharyngeum Tubæ). *Monatschr. f. Ohrenheilk. u. Laryngo-Rhinol.*, 1913, xl, 262.
By Zentralbl. f. d. ges. Chir. u. i. Grenzgeb.

A young physician, who since childhood frequently suffered from angina and nasal catarrh, complained for two years of symptoms pointing to closure of the Eustachian tube. By means of posterior rhinoscopy and salpingoscopy a yellowish white tumor, the size of a pea, was seen on the upper surface of the right tubal opening, in part covering the tube and in part compromising it. A second small tumor was situated in the pharyngeal tonsil. The first tumor was removed through the nose by means of a snare and the second was removed with the entire tonsil containing it. Both tumors were cysts lined by flat epithelium. They were probably due to epithelial inclusion and cystic degeneration, following chronic inflammatory processes. The literature of benign and malignant tumors occurring in this region is given.

KLEINSCHMIDT.

Ray: The Tonsil Question Again. *Louisville Month. J.*, 1913, xix, 353.

By Surg., Gynec. & Obst.

The purpose of the paper is to insist that the operator use judgment in selecting his cases, and surgical skill in carrying out the procedure. The author first takes up the essentials of the embryology, anatomy and physiology of the tonsil with its life history and the evidence in support of the belief in an internal secretion. He does not believe that the tonsils play any great part as portals of entry for infection in either rheumatism or tuberculosis.

His indications for removal are as follows: simple hypertrophy causing obstruction, cases of frequent recurring attacks of follicular tonsillitis, in relapsing attacks of peritonsillar abscess, and in growths originating in the tonsil, also in some toxic conditions where the crypts are large and contain decomposing masses. He does not consider that the removal is indicated in middle ear disease nor as a cure for the enlargement of the cervical glands.

In the discussion there was little else brought out as all of the men felt much as the author did in regard to the indications. The majority were in favor of tonsillectomy in every case though a small portion of the lower pole might be left to functionate.

EARLE B. FOWLER.

Carter: A Simple and Satisfactory Method for Removing Adenoids and Tonsils. *Med. Rec.*, 1913, lxxxiii, 986.

By Surg., Gynec. & Obst.

In removal of the tonsil with the capsule the author uses a spiral tenaculum which consists of two

spiral prongs, each compassing half a circle, attached to a long, slender shaft. These prongs are made only a half circle in length in order that it may be quickly and easily engaged and disengaged. With this the tonsil is pulled toward the median line. The tonsil separator consists of a short beveled blade, curved on the flat, sharp on both sides and the end, and is used to cut through the plica and the mucous membrane along the margin of the pillars. The tonsil is pried out from its bed, using the separator as a lever. The removal is completed with an Eve's snare.

Adenoids are removed by one sweep of a Gottstein curette and the naso-pharynx wiped out by gauze wrapped around the finger.

EARLE B. FOWLER.

Hope: Laryngeal Tumor Treated with Seleniol. *Proc. Roy. Soc. Med.*, 1913, vi, Laryngol. Sect., 76.

By Surg., Gynec. & Obst.

The case reported was a male, 53 years old, suffering for several months with increasing dyspnea. Examination revealed the right arytenoid and ventricular band replaced by a large, red, smooth swelling, non-mobile. Neither cord could be seen and there was practically no glottis. Diagnosis was made of swelling above a malignant ulceration. There was definite thickening on the right side of the neck over the right ala of the thyroid and a small hard gland could be palpated.

Operative treatment was not advised because of the patient's general condition. Seleniol (3cc.) was injected three times a week into the deep tissues near the right ala of the thyroid cartilage. Great relief was experienced after the second injection.

One month later, by the direct method, a large fungating mass was seen involving the right side of the epiglottis on its laryngeal surface, extending down through the glottis. Two weeks later the mass had largely disappeared.

Seleniol is an electrolytic colloid of the metal selenium, and may be injected subcutaneously, intravenously or directly into the tumor. There is absolutely no toxic effect and the growth is said to either absorb or liquefy.

EARLE B. FOWLER.

Levy: Laryngeal Tuberculosis. *J. Am. M. Ass.*, 1913, lx, 1518.

By Surg., Gynec. & Obst.

The author emphasizes very strongly the importance of early laryngeal examination in all cases of tuberculosis, referring to the strong way this has been brought forward in Germany. Among the earliest signs we find slight, intermittent hoarseness. It is followed in many cases by a unilateral lesion with or without slight redness and moderate swelling, usually occurring on the same side as the affected

lung. The onset of tubercle deposit in the sub-mucous tissue is frequently marked by early pain and shows by a physical examination as a circumscribed pale oedematous swelling with small grayish or yellowish, pin-point elevations distinctly beneath the mucosa and imbedded in it. Rubbing the surface with a firm swab and examining it bacteriologically will often result in demonstrating the organism.

The prognosis is fair and improving. Brull gives the percentage of cures as 58.

In line of treatment the author advocates:

1. Rest of the vocal organ associated with general hygienic measures.
2. Galvanic-cautery.
3. Relief of pain by injection or section of the superior laryngeal nerve.
4. The use of tuberculin. EARLE B. FOWLER.

Richardson: The Treatment of Laryngeal Stenosis Following Diphtheria. *Boston M. & S. J.*, 1913, clxviii, 749. By Surg., Gynec. & Obst.

Stenosis of the larynx following an attack of laryngeal diphtheria occurs in only 1 to 3 per cent of the cases. It is generally the result of poor intubation technique (especially the use of an undue amount of force), prolonged intubation, a very severe infection or secondary infection. One or more of these factors result in pathological changes consisting of thickening of the mucosa, paresis of the muscles of the cords, granulations or ulcerations with formation of cicatricial bands, or a persistent membrane.

As the prophylaxis against these conditions the author advocates the use of carefully selected intubation tubes, skillfully applied and not allowed to remain in place over one month. His active treatment consists of a low tracheotomy, which puts the parts at rest, followed by dilatation with straight urethral dilators or tubes increasing the size to a maximum. These are permitted to remain only a few minutes at each sitting and are not worn.

Richardson reports nine cases to support his belief in the value of this method.

EARLE B. FOWLER.

Higgins: Apparently Non-Suppurative Nasal Sinus Disease. *Wis. M. J.*, 1913, xi, 369. By Surg., Gynec. & Obst.

The author has written an original article describing a frequently undiagnosed non-suppurative

nasal disease of the accessory sinuses, unassociated with pus and characterized by a watery mucus discharge, sneezing, especially in the morning, asthma, due to reflex irritation, cough, dry or in paroxysms, pain, varying in location with the sinus involved, deafness, due to nasal congestion, asthenopia and disturbance of the visual field. The physical signs upon which a diagnosis is based need not be pronounced.

He thinks that rhinologists have erred in the belief that all sinus disease must reveal itself by the appearance of pus either by drainage or demonstrated by negative pressure as applied through the agency of Brawley's suction apparatus. Higgins states that if the ultimate diagnosis is based upon the findings of pus, many cases will go undiagnosed and untreated where treatment is urgently indicated; for there is a nasal sinus disease without pus discharge, and yet with sufficient pathology to produce polyps, granulation tissue and necrosed bone, as well as vascular and lymphatic stasis.

The author advocates operation in certain cases of negative findings including the newly described non-suppurative disease, as well as some suppurative cases in which the usual diagnostic methods do not positively indicate pus. ELLEN J. PATTERSON.

Iglauer: Suspension Laryngoscopy; with Report of Cases. *Lancet-Clin.*, 1913, cix, 702. By Surg., Gynec. & Obst.

The article tells of the manner in which this method was discovered by Killian; an exact description of the instrument and the technique of its use; a report of six diagnostic and operative cases demonstrating its advantages.

In this method a hook spatula, which includes the tongue blade, is suspended from a gallows, thereby doing away with the necessity of holding it and permitting of direct examination of the larynx, the patient lying in the dorsal position. The patient takes a passive part in the procedure; suffers but little discomfort; can tolerate prolonged operations within the larynx, and is not annoyed by saliva or blood flowing into trachea. The operator works in an easy position, with both hands free, and has a wide field of vision with the larynx at close range and ample space for all necessary manipulation. The pathology and the surgery of the larynx can be better demonstrated to students by this method.

EARLE B. FOWLER.

Surgical importance of the breast. E. D. MARTIN. Southern M. J., 1913, vi, 327.

Fractures of the sternum. W. VON BRUNN. Zentralbl. f. Chir., 1913, xl, 633.

Enchondroma of the manubrium sterni successfully removed by operation. W. G. RICHARDSON. Brit. M. J., 1913, i, 985.

Enchondroma of the scapula. W. D. MININGHAM. N. Y. M. J., 1913, xcvi, 1128.

Osteosarcoma of the shoulder-blade. GUACCERO. Clin. chir., Milano, 1913, xxi, No. 4.

Penetrating combined thoracic and abdominal wounds. GULEKE. Deutscher chir. Kong., 1913. [274]

Case of congenital thoracic deformity. CROOKSHANK and BOYD. Proc. Roy. Soc. Med., 1913, vi, Sect. Dis. Children, 152. [274]

A wound of the chest complicated by injury of the internal mammary artery. DESGOUTTES and LAMBERT. Lyon méd., Par., 1913, cxx, No. 19.

On the question of artificial pneumothorax. L. HOFBAUER. Ztschr. f. physikal. u. diätet. Therap., 1913, xvii, 265.

The practical value of the indications and contraindications for artificial pneumothorax in the treatment of pulmonary tuberculosis. BURNAND. Rev. méd. de la Suisse Rom., Geneve, 1913, xxxiii, No. 4.

Fulminant secondary hæmothorax. LARDENNOIS. Gaz. d. hôp., Par., 1913, lxxxvi, No. 56.

Malignant primary tumor of the pleura. LESIEUR, SAVY and MAZEL. Arch. de méd. exp. et d'anat. Path., Par., 1913, xxv, No. 3.

An abnormal vein in the mediastinal region. DELATTRE. J. d. sc. méd. de Lille, 1913, xxxvi, No. 18.

False diagnosis of croup in children affected with tuberculosis of the bronchial glands and of the body of the vertebræ. M. MICHALOWITSCH. Pädiat., 1913, iv, 121.

Diagnosis of thoracic gland tuberculosis in childhood. J. C. ABBOTT. W. Va. M. J., 1913, vii, 371.

The thymus and the other ductless glands. R. PARK. Cleveland M. J., 1913, xii, 329. [274]

About thymus and the combination of thymus-hyperplasia with Basedow's disease. A. ELSAESSER. Ohio St. M. J., 1913, ix, 220.

Polynuclear leucocytosis in the thymus gland following X-ray treatment. REGAUD and CREMIEN. Compt. rend. Soc. de biol., Par., 1913, lxxiv, 862.

Report of two cases of enlarged thymus. H. A. HULL. Iowa M. J., 1913, xix, 557.

Röntgen ray treatment of thymus hypertrophy. C. W. WYCKOFF. Cleveland M. J., 1913, xii, 341. [275]

Trachea and Lungs

My new method for radiographic representation of the larynx and the trachea. A. RÉTHI. Ztschr. f. Laryngol., Rhinol. u. i. Grenzgeb., 1913, vi, 27.

Clinical contributions on the etiology and symptomatology of intratracheal stenosis. G. COHN. Ztschr. f. Laryngol. u. i. Grenzgeb., 1913, vi, 35.

Operations for tracheal tumors. BROECKAERT. Ann. Soc. belge de Chir., 1913, xxxi, 38. [275]

The surgical treatment of bronchiectasis. BATZDORFF. Zentralbl. f. d. Grenzgeb. d. Med. u. Chir., 1913, xvi, Nos. 5-6.

Injuries to lungs and pleura; with report of a case. P. Z. McDONALD. Illinois M. J., 1913, xxiii, 497.

Operative or conservative treatment of injuries of the lung by pointed instruments. E. VON KUTSCHA. Wien. klin. Wchnschr., 1913, xxvi, 737.

Gangrene of the lung and its treatment. G. TREUPEL. Deutsche med. Wchnschr., 1913, xxxix, 777.

Ossification of the lung. OSSLAN. Riv. osp., Roma, 1913, iii, No. 9.

Primary carcinoma of the lung. M. S. GESSELEWITSCH. Vrach. Gaz., St. Petersburg., 1913, xx, 527.

The so-called "Schneeberger" pulmonary cancer. ARNSTEIN. Wien. klin. Wchnschr., 1913, xxvi, No. 19.

Generalized cancerous lymphangitis of the lung. BERNARD and CAIN. Arch. de méd. exp. et d'anat. Path., Par., 1913, xxv, No. 3.

The operative treatment of lung embolism. SCHUMACHER. Deutscher chir. Kong., 1913. [275]

A pulmonary abscess which developed a long time after typhoid. GIORDANO. Riforma med., 1913, xxix, No. 20.

A case of Wilms' operation for unilateral pulmonary tuberculosis. L. MAYER and N. GEERAERD. J. méd. de Bruxelles, 1913, xviii, 140.

Emphysema. PLESCH. Deutsche med. Wchnschr., 1913, xxxix, No. 19.

A contribution on Freund's emphysema operation. JESSEN. München. med. Wchnschr., 1913, lx, No. 19.

Effect of extensive resection of the thoracic wall on marked pulmonary emphysema. FRIEDERICH. Deutscher chir. Kong., 1913. [276]

Experiences in surgery on the superior respiratory and digestive tracts. GLUCK. Berl. klin. Wchnschr., 1913, l, No. 21.

Heart and Vascular System

Further experience of the cardiac sign in cancer. W. GORDON. Brit. M. J., 1913, i, 1152.

The surgery of the heart and the pericardium. JAS. RAE. Universal M. Rec., 1913, iii, 391.

Sequel of a case of cardiolytic. R. SIMON. Brit. M. J., 1913, i, 1050.

The question of cardiac suture. A. DROSDOW. Med. Rundschau, 1913, lxxxix, 439.

Pharynx and Oesophagus

Diagnosis and treatment of foreign bodies in the oesophagus. A. JURASZ. Ergebn. d. Chir. u. Orthop., 1913, v, 361.

Foreign bodies in the oesophagus. P. LE JEUNE. Ann. Soc. méd.-chir. de Liege, 1913, lii, 56.

Foreign body in the oesophagus removed by oesophagoscopy; 2. Foreign body in bronchial tract. H. DUPUY. New Orleans M. & S. J., 1913, lxxv, 815.

Oesophagotracheal fistula, with recurrent paralysis caused by a foreign body in the oesophagus. M. KÖNIGSTEIN. Monatschr. f. Ohrenheilk. u. Laryngo-Rhinol., Berl., 1913, xlvii, 522.

Spasms of the superior extremity of the oesophagus. RABASA. Arch. internat. de laryngol., d'otol. et de rhinol., Par., 1913, xxxv, No. 2.

The treatment of cicatricial stenoses of the oesophagus, with special consideration of internal oesophagotomy. H. MARSHIK. Monatschr. f. Ohrenheilk. u. Laryngo-Rhinol., Berl., 1913, xlvii, 279.

Treatment and diagnosis of cicatricial stenoses of the oesophagus. GUISEZ. Arch. internat. de laryngol., d'otol. et de rhinol., Par., 1913, xxv, No. 2.

Chronic inflammatory stenosis of the cardiac region of the oesophagus. LIEBAULT. Inaugural thèse, Par., 1913. [276]

Cancer of oesophagus from the point of view of thoracic surgery. W. MEYER. Arch. f. klin. Chir., 1913, c, 716.

The surgical treatment of cancer of the oesophagus. W. MEYER. Med. Rec., 1913, lxxxiii, 888. [276]

The first successful resection of the thoracic portion of the oesophagus for carcinoma; a preliminary report. F. TOREK. J. Am. M. Ass., 1913, lx, 1533.

Further contributions on surgery of the oesophagus. REHN. Zentralbl. f. Chir., 1913, xl, 558.

Plastic surgery of the oesophagus from the gastric wall. E. PFLAUMER. Zentralbl. f. Chir., 1913, xl, 684.

Miscellaneous

Röntgen diagnosis of intra-thoracic lesions. A. L. GRAY. Southern M. J., 1913, vi, 295.

Some remarks on the diagnosis of primary intrathoracic malignant disease. W. H. M. TELLING. Clin. J., 1913, xlii, 65.

Endoscopic diagnosis and treatment of endothoracic tumors. A. EPHRAIM. Berl. klin. Wchnschr., 1913, l, 685.

Rare forms of hæmorrhages in the gastro-intestinal tract. STADELMANN. Berl. klin. Wchnschr., 1913, l, No. 18.

The pathological effect of the ascarides in relation to surgical affections. R. CINAGLIA. Gazz. d. osp. e d. clin., 1913, xxxiv, 450.

Liver, Pancreas, and Spleen

The necessity of the examination of the liver in the upright position. PLANTIER. Paris méd., 1913, ii, No. 25.

Anomalies of the left lobe of the human liver. G. RUGE. Morphol. Jahrb., Leipz., 1913, xlv, 409.

Injuries of the liver, according to the data of the surgical

department of the Obuchow City Hospital for men in St. Petersburg. BOLJARSKY. Russk. Vrach, 1913, xii, 287. [290]
Casuistic and experimental contributions on rupture of the liver and the bile-ducts. ORTH. Arch. f. klin. Chir., 1913, ci, No. 2.

Acute yellow atrophy of the liver. W. E. STEWART. J. Okla. St. M. Ass., 1913, v, 525.

Syphilis of the liver. T. W. STUMM. St. Paul M. J., 1913, xv, 199.

Differential diagnosis of hydatid cysts and abscesses of the liver. GAIDE. Ann. d'hyg. et de méd. colonial, Par., 1913, xvi, No. 1.

A case of abscess of the liver in appendicitis. G. J. BARDADULIN. Chirourgia, St. Petersburg, 1913, xxxiii, 214.
Costal caries as a secondary symptom of abscesses of the liver. LECOMTE. Ann. d'hyg. et de méd. colonial, Par., 1913, xvi, No. 1.

A series of twenty personally observed cases of abscess of the liver in cold climates. PERVERS and OUDARD. Arch. de méd. et de pharm. nav., Par., 1913, No. 4, April.

Sarcoma of the liver associated with bilateral diffuse sarcomatosis of the kidneys in a rooster. LUDWIG. Ztschr. f. Krebsforsch., Berl., 1913, xiii, No. 2.

The radical operation of alveolar echinococcosis of the liver. MOUTCH. Chir. arch. Veliaminova, St. Petersburg, 1913, xxix, No. 2.

Statistical, clinical and chemical studies on the etiology of gall-stones, with special consideration of conditions in Germany and in Japan. MIYAKE. Arch. f. klin. Chir., Berl., 1913, ci, No. 1.

Treatment of gall-stones. J. PERRINS. Eclect. Rev., 1913, xvi, 139.

Chronic icterus due to retention; stenosis of the ductus choledochus; choledcho-duodenostomy. BRAULT and GRÉGOIRE. Bull. et mém. Soc. Méd. d. Hôp. de Par., 1913, xxix, 855. [291]

Acute calculous occlusion of the choledochus, with statistical and technical remarks. HEIDENHAIN. München. med. Wchnschr., 1913, lx, No. 19.

The frequency of aërophagy associated with biliary lithiasis. MAUBAN. Arch. d. mal. de l'appar. dig. et de la nutrit., Par., 1913, vii, No. 4.

Contribution to the knowledge of congenital atresia of the bile-ducts. F. VANZETTI. Arch. p. le sc. med., Torino, 1913, xxxvii, 1.

The origin of the so-called "white bile" in permanent occlusion of the choledochus. J. BERTO. Mitt. a. d. Grenzgeb. d. Med. u. Chir., 1913, xxvi, 49.

Inhibitive action of bile on bacillus coli. E. O. JORDAN. J. Infect. Dis., 1913, xii, No. 3.

Growths in the gall-bladder and growths in the bile-ducts. S. PHILLIPS. Lancet, Lond., 1913, clxxxiv, 1442.

Acute perforation of the gall-bladder; with an account of six cases. L. R. BRAITHWAITE. Brit. M. J., 1913, i, 1096.

The complications of cholecystitis as shown by the experiences of the last three years. B. HOLMES. Lancet-Clin., 1913, cix, 534.

Cholelithiasis and cholecystitis in infancy and its treatment. KHAUTZ. Zentralbl. f. d. Grenzgeb. d. Med. u. Chir., 1913, xvi, No. 5.

Can cholelithiasis be successfully treated without operation? T. H. DELANY. Indian M. Gaz., 1913, xlviii, 180.

The technique of surgery of the gall-bladder and the bile ducts. F. C. EGGERT. Illinois M. J., 1913, xxiii, 497.

Surgery of the biliary passages. J. S. HAGEN. Eclect. M. J., 1913, lxxiii, 225.

Operative treatment of affections of the bile-ducts. PAUS. Nord. Med. Ark., Stockholm, 1913, xlv, May.

On the secretion of pancreatic juice. I. MATSUO. J. Physiol., 1913, xlv, 447.

The importance of quantitatively determining pancreatic ferments in the fæces for the diagnosis of lesions of the pancreas. P. F. ZUCCOLA. Riforma méd., 1913, xxix, 393.

Pathology of the pancreas. Cystic cavities in the islands of Langerhans. L. W. SSABOLEW. Zentralbl. f. allg. Path. u. path. Anat., 1913, xxiv, 341.

The pathology of the pancreas. APOLANT. Virchows Arch. f. path. Anat. u. f. klin. Med., 1913, ccxii, No. 2.

Pancreatic affections and rare affections of the duodenum and their value for the differential diagnosis of duodenal ulcer. FRIEDRICH. Duetscher chir. Kong., 1913. [291]

Pancreatitis. KOCH. Nederl. Tijdschr. v. Geneesk., 1913, i, No. 15.

Pancreatitis. PEL. Nederl. Tijdschr. v. Geneesk., 1913, i, No. 15.

Liposis pancreatica. E. J. MULLALLY. Canad. M. Ass. J., 1913, iii, 382.

Experimental and clinical relations between necrosis pancreas and cholecystitis on the one hand and cholelithiasis on the other. NORDMANN. Deutscher chir. Kong., 1913. [292]

A case of serous cyst of the pancreas. NOVARO. Riv. osp., Roma, 1913, iii, No. 9.

Solitary hydatid cyst of the head of the pancreas. CRAGLIETTO. Clin. chir., Milano, 1913, xxi, No. 4.

The surgical significance of the accessory pancreas. CAWARDINE and SHORT. Ann. Surg., Phila., 1913, lvii, 653. [292]

Banti's disease in infancy; two cases of Banti's disease in earliest infancy. D'ESPINE. Rev. méd. de la Suisse Rom., Genève, 1913, xxxiii, No. 5.

Cysts of the spleen. R. H. FOWLER. Ann. Surg., Phila., 1913, lvii, 658. [292]

Splenectomy. M. A. TATE. Lancet-Clin., 1913, cix, 477.

Death from internal hæmorrhage seven days after an injury of the spleen. H. HAHN. Med. Klin., 1913, ix, 585.

Miscellaneous

The abdomen; an important factor in chronic joint affections. F. E. PECKHAM. Am. J. Orth. Surg., 1913, x, 80.

Diagnosis of the acute abdominal conditions of children. E. M. CORNER and E. CAUTLEY. Practitioner, Lond., 1913, xc, 798. [293]

Suppurative conditions of the upper abdomen. B. F. ZIMMERMAN. Ky. M. J., 1913, xi, 400.

On the question of penetrating abdominal wounds. K. S. SUMURAWKIN. Voenno-med. J., St. Petersburg, 1913, ccxxxvi, 373.

Bullet wound of the abdomen associated with lesions of the rectum, the colon, the mesentery and the omentum; recovery. CORMIO. Policlin., Roma, 1913, xx, No. 17.

The consideration of a few points in visceral ptosis. W. S. NEWCOMET. Penn. M. J., 1913, xvi, 639.

The cause of epigastric pain. G. FARNOLI. Gazz. d. osp. e d. clin., Milano, 1913, xxxiv, 519.

Spontaneous eversion, treated and cured by abdominal gymnastics. WALTHER. Bull. et mém. Soc. de chir. de Par., 1913, xxxix, 747.

Laparo- and thoracoscopy. H. C. JACOBÆUS. Beitr. z. klin. d. Tuberkul., 1913, xxv, 2. [293]

A plea for early laparotomy in abdominal diseases. A. GOLDMAN. Med. Rec., 1913, lxxxiii, 981.

The importance of surgical interventions in the abdominal cavity in children. D. BALÁS. Beitr. z. klin. Chir., 1913, lxxxiv, 61.

SURGERY OF THE EXTREMITIES

Diseases of Bones, Joints, Muscles, Tendons — General Conditions Commonly Found in the Extremities

The chemistry of bone marrow; the fifth communication on "The chemistry of the blood in diseases." H. BEUMER and M. BÜRGER. *Ztschr. f. exp. Path. u. Therap.*, 1913, xiii, 367.

Experimental contributions to the pathogenesis of acute hæmatogenous osteomyelitis. F. L. DUMONT. *Deutsche Ztschr. f. Chir.*, 1913, cxxi, 116. [294]

Osteomyelitis in earliest infancy; osteomyelitis of the radius; osteomyelitis of the superior extremity of the femur; the microbic nature of these osteomyelites in earliest infancy; importance of streptococcic infections. E. KIRMISSON. *Bull. méd., Par.*, 1913, xxvii, 243.

Infectious osteomyelitis. KLEMM. *Beitr. z. klin. Chir.*, 1913, lxxxiv, No. 2.

Localized osteomyelitis of the long bones. C. C. SIMMONS. *Boston M. & S. J.*, 1913, clxviii, 637.

Atrophy of the femoral neck as a secondary symptom of osteomyelitis in early infancy; coxa vera. GASNE. *Rev. d'orthop., Par.*, 1913, iv, No. 3.

Tuberculous osteomyelitis of the digits. R. M. GREEN. *Boston M. & S. J.*, 1913, clxviii, 797.

Tuberculosis of the bones and joints and its homœopathic treatment. A. N. ROGATCHEVSKY. *North Am. J. Homœop.*, 1913, xxviii, 285.

Tuberculin reaction at the focus in tuberculosis of bones and joints. F. DELITALA. *Arch. di ortop., Milano*, 1913, xxx, 12.

The treatment of osteo-articular tuberculosis. GARRÈ. *Arch. f. klin. Chir., Berl.*, 1913, ci, No. 2.

The treatment of osteo-articular tuberculosis in infancy. BARBARIN. *Clinique, Par.*, 1913, viii, No. 19.

Radiographs of diaphyseal tuberculosis of the long bones. BROCA and PHILBERT. *Paris méd.*, 1913, No. 24.

Modern efforts directed toward a conservative treatment of surgical tuberculosis. ROTHSCHILD. *Zentralbl. f. d. Grenzgeb. d. Med. u. Chir.*, 1913, xvi, No. 5.

Light-treatment of surgical tuberculosis. VULPIUS. *München. med. Wchnschr.*, 1913, lx, No. 20.

The treatment of surgical tuberculosis in special sanatoria. VULPIUS. *Med. Klin.*, 1913, ix, No. 19.

Post-typhoid osteo-periostitis. TOURNEUX and GINESTY. *Province méd., Par.*, 1913, xxvi, No. 21.

Osteitis deformans (Paget's disease). W. G. THOMPSON. *Med. Rec.*, 1913, lxxxiii, 832.

Some diagnostic features of certain intra-osseous lesions, astitis fibrosa, bone cyst, and their relation to other intra-osseous lesions. A. H. FREIBERG. *Lancet-Clin.*, 1913, cix, 504.

Diagnosis and treatment of Morton's disease. HORODYNSKI. *Gaz. lék., Warszawa*, 1913, xxxiii, No. 19.

Tumors of bone. S. B. CHILDS. *Colo. Med.*, 1913, x, 159.

A primary asarantinoma of the tibia. B. FISCHER. *Frankf. Ztschr. f. Path.*, 1913, xii, 422.

Osseous plasmomata. K. NECKARSULMER. *Mitt. a. d. Hamburg. Staatskrankenanst.*, 1913, xii, 175.

Köhler's disease of the scaphoid bone in children is not a fracture. KÖHLER. *Arch. f. klin. Chir.*, 1913, ci, No. 2.

A case of acute osseous atrophy. MÜLLER. *Deutsche mil.-ärztl. Ztschr.*, 1913, xlii, No. 9.

A radiographic study of traumatism of the carpal bones. CHAPUT and VAILLANT. *Rev. d'orthop., Par.*, 1913, xxiv, 227.

Accommodation in ankyloses of the fingers. THIEM. *Monatschr. f. Unfallheilk. u. Invalid.-Wes.*, 1913, xx, No. 5. A peculiar typical deformity of the styloid process of the ulna. REICHT. *München. med. Wchnschr.*, 1913, lx, No. 21.

A case of arrested development of the femur. PERRIN. *Rev. d'orthop., Par.*, 1913, xxiv, 285.

Etiological studies in osteo-arthritis. L. A. O. GODDU. *Am. J. Orth. Surg.*, 1913, x, 142.

A case of hypertrophic osteo-arthritis of pneumococcus origin in a child four years of age. V. FRAGALE. *Gazz. internaz. di med., chir., Napoli*, 1913, i, 54.

The structure and mechanism of the human joints in health, disease, and injuries. G. G. DAVIS. *Am. J. Orth. Surg.*, 1913, x, 30.

Diseases of joints and bone marrow. L. W. ELY. *Am. J. Surg.*, 1913, xxvii, 179.

Hydrarthrosis. PULAWSKI. *Gaz. lék., Warszawa*, 1913, xxxiii, No. 20.

Tabetic arthropathy of the knee; resection; cure. R. FALCONE. *Riforma méd.*, 1913, xxix, 421.

An X-ray study of gastro-intestinal findings in multiple arthritis. G. R. ELLIOTT. *Am. J. Orth. Surg.*, 1913, x, 56.

Static joint diseases, their etiology and their relation to arthritis deformans. G. PREISER. *Am. J. Orth. Surg.*, 1913, x, 100.

Some considerations on the pathogenesis and treatment of toxic arthritis. P. W. NATHAN. *Am. J. Orth. Surg.*, 1913, x, 69.

Physiotherapy of chronic affections of the joints, with special consideration of thermotherapy. B. BUXBAUM. *Zentralbl. f. d. ges. Therap.*, 1913, xxxi, 225.

Chronic arthritis; therapeutic evidence of the incidence of streptococcal infection. D. W. C. JONES. *Brit. M. J.*, 1913, i, 1047.

The etiology of chronic non-tuberculous arthritis—the mis-called arthritis deformans. L. W. ELY. *Am. J. Orth. Surg.*, 1913, x, 171.

Experimental streptococcal arthritis in rabbits. L. JACKSON. *J. Infect. Dis.*, 1913, xii, No. 3.

Gonorrhœal arthritis. E. J. ANGLE. *Am. J. Clin. Med.*, 1913, xx, 405.

The treatment of gonorrhœal pseudo-rheumatism by the antimeningococcic serum of Dopter. BARBE. *Arch. de méd. et de pharm. nav., Par.*, 1913, No. 4.

Treatment of gonorrhœal arthritis by the antimeningococcic serum. LASSERRE. *J. de méd. de Bordeaux*, 1913, xliii, No. 19.

The serum therapy of meningococcus arthritis. H. L. TAYLOR. *Cleveland M. J.*, 1913, xii, 348.

A contribution to the etiology of rheumatoid arthritis. W. CROWE. *Lancet, Lond.*, 1913, clxxxiv, 1377.

Rheumatism: its etiology and pathology. J. A. OWEN. *Va. M. Semi-Month.*, 1913, xviii, 90.

The diagnosis of the tubercular character of joint disease. E. G. BRACKETT. *Boston M. & S. J.*, 1913, clxviii, 673.

Contribution to the study of juxta-articular tuberculosis of the hip-joint. F. DELITALA. *Bull. d. sc. méd.*, 1913, lxxxiv, 53.

Casuistics of traumatic inflammations of the hip-joint. Z. BRIND. *Monatschr. f. Unfallh. u. Invalidenwes.*, 1913, xx, 111.

Fixation in the treatment of hip disease. E. H. BRADFORD. *Am. J. Orth. Surg.*, 1913, x, 354.

The mechanical treatment of hip disease. G. B. PACKARD. *Am. J. Orth. Surg.*, 1913, x, 329.

Results in hip tuberculosis after mechanical treatment

(without traction and hygiene). H. L. TAYLOR. *Am. J. Orth. Surg.*, 1913, x, 333.

Treatment of various affections of the joints, including tuberculous affections, and cold abscesses by means of camphorated phenol. PUHL. *Zentralbl. f. Chir.*, 1913, xl, No. 21.

Radiographic study of ossification around the knee-joint in the new-born. DELHERM. *Bull. off. soc. franc. d'électrotherap. et de radiol.*, 1913, xxi, 9.

Injuries to the semilunar cartilages of the knee-joint. R. MORISON. *Clin. J.*, 1913, xlii, 1. [295]

Bruise of the right knee; tetanus; open fracture of the right fibula. CAULLI. *Riv. osp.*, Roma, 1913, iii, No. 8.

Penetrating wounds of the knee-joint. MÜLLER. *Arch. f. klin. Chir.*, 1913, ci, No. 2.

Arborescent lipoma of the knee. LEFEVRE and DUBOURG. *Arch. gén. de chir., Par.*, 1913, vii, No. 4.

A case of Volkmann's ischæmic contracture of the hand. G. DE SWIETECHOWSKI. *Lancet, Lond.*, 1913, clxxxiv, 1380.

Congenital familiar contracture of the joints of the little finger. SCHULTZE. *Zentralbl. f. d. Grenzgeb. d. Med. u. Chir.*, 1913, xvi, No. 5.

A consideration of the action of the extrinsic and intrinsic muscles of the foot from an anatomical and mechanical standpoint. L. T. BROWN. *Am. J. Orth. Surg.*, 1913, x, 18.

Tuberculosis of the supraspinatus muscle. J. T. RUGH. *Am. J. Orth. Surg.*, 1913, x, 603.

Muscle abscess due to typhus bacilli occurring in the course of typhoid fever. AYUTA and KURAMOTO. *Saikin-gaku-Zasshi, Tokyo*, 1913, No. 209.

Myositis. JACOB. *München. med. Wchnschr.*, 1913, lx, No. 20.

Multiple myeloma. T. SHENNAN. *Edinb. M. J.*, 1913, x, 414.

The treatment of spastic contractures. A. STOFFEL. *Am. J. Orth. Surg.*, 1913, x, 611.

Contribution on hysterical contractures after accident. H. HARTTUNG. *Arch. f. Orthop., Mechanotherap. u. Unfallchir.*, 1913, xii, 114. [295]

Subcutaneous ruptures of the flexor tendons of the fingers. PFÖRRINGER. *Monatschr. f. Unfallheilk. u. Invalid.-Wes., Leipz.*, 1913, xx, No. 5.

Pathological anatomy of tendinous synovitis with rizziform granules and the mode of formation of the limiting synovial-membrane and the granules. FORGUE and ÉTIENNE. *Rev. de chir., Par.*, 1913, xxxiii, No. 5.

The treatment of phlegmons of the synovial sheaths of the hand after Lecène's method. LEFEVRE. *Province méd., Par.*, 1913, xxvi, 194.

Tearing of the tendon of the quadriceps and of the patellar ligament. JANASZEK. *Wien. klin. Rundschau*, 1913, xxvii, Nos. 20-21.

A case of syphilitic bursitis. CLAUSEN. *Ugesk. f. Laeger, Kjøbenh.*, 1913, lxxv, No. 18.

Infective inflammation of hand. J. J. DIAL. *J. Okla. St. M. Ass.*, 1913, v, 539.

Treatment of felons with reference to the pathological anatomy and location of incisions. G. M. DORRANCE. *J. Am. M. Ass.*, 1913, lx, 1416. [296]

A painful variety of adiposis of the lower limbs, which were affected with sciatica. FAVRE and TOURNADE. *Lyon méd.*, 1913, cxx, No. 19.

Elephantiasis neurofibromatosis of the foot with general neurofibromatosis. F. T. RUGH. *Am. J. Orth. Surg.*, 1913, x, 606.

Fractures and Dislocations

Some unusual fractures. W. H. SPEER. *Dela. St. M. J.*, 1913, iv, 1.

Fracture of the long bones. S. D. VAN METER. *Therap. Gaz.*, 1913, xxxvii, 305.

Röntgen interpretation of a few common type fractures. A. SOILAND. *Western M. News*, 1913, v, 5.

Two cases of rare tabetic bone fractures. SCHLEINZER. *Wien. med. Wchnschr.*, 1913, lxiii, No. 21.

Reduction of fragments under local anaesthesia. DOLLINGER. *Zentralbl. f. Chir.*, 1913, xl, No. 20.

Longitudinal fissured fracture of the lower end of the radius. J. L. BENDELL. *J. Am. M. Ass.*, 1913, lx, 1537.

Treatment of fractures of the radius. TRÖLL. *Arch. f. klin. Chir.*, 1913, ci, No. 2.

Massage and mobilization of fractures of the elbow in infancy. RÖDERER. *Clinique, Par.*, 1913, viii, No. 21.

Diagnosis and treatment of fractures in the region of the elbow-joint. T. VOECKLER. *Med. Klin.*, 1913, ix, 441. [296]

Fractures of the pelvis. JENSEN. *Arch. f. klin. Chir.*, 1913, ci, No. 1.

Fracture of the acetabulum. U. MAES. *New Orleans M. & S. J.*, 1913, lxxv, 825.

Reduction of fractures and luxations of the lower limbs under spinal anaesthesia. ROBINEAU. *Clinique, Par.*, 1913, viii, No. 20.

Fractures of the lower limb treated while permitting the patient to walk about. BAUMBACH. *Cor.-Bl. d. allg. ärzt. Ver. v. Tübing.*, 1913, xlii, 216.

A clinical lecture on fractured femur. C. G. WATSON. *Clin. J.*, 1913, xlii, 97.

Shattering of the femur with extensive compound injury of soft parts; recovery without operation with useful limb. J. Am. M. Ass., 1913, lx, 1343.

Injuries to the condylar cartilages. E. BARREAU. *Beitr. z. klin. Chir.*, 1913, lxxxiii, 688. [297]

Treatment of the spiral fractures of the tibia. G. LEVISON. *Calif. St. J. Med.*, 1913, xi, 188.

Fractures of the calcaneum. BRAND. *Nederl. Tijdschr. v. Geneesk.*, 1913, i, No. 14.

Fractures of the greater tuberosity of the calcaneus. SOUBEYRAN and RIVES. *Arch. gén. de chir.*, 1913, vii, No. 4.

Treatment by extension, of fractures of the calcaneum and of the metatarsus. GELINSKY. *Zentralbl. f. Chir.*, 1913, xl, No. 21.

A lecture on birth palsy: subluxation of the shoulder-joint in infants and young children. H. A. T. FAIRBANK. *Lancet, Lond.*, 1913, clxxxiv, 1217.

A case of complete anterior dislocation of both bones of the fore-arm at the elbow. R. WINSLOW. *Surg., Gynec. & Obst.*, 1913, xvi, 569. [297]

Cases illustrative of (1) fracture of carpal scaphoid with luxation of semilunar, (2) fracture of carpal scaphoid with palpable deformity. P. G. SKILLERN. *J. Am. M. Ass.*, 1913, lx, 1536.

The true luxation of the hand. R. GILLERSON. *Disertation, Strassburg*, 1913.

Traumatic dislocation of the right sacro-iliac synchondrosis in a girl twenty-one months old; cure. BRAQUEHAYE, ADDA and BRUCH. *Arch. de méd. d. enfants, Par.*, 1913, xvi, No. 5.

Luxatio centralis femoris. Z. BRIND. *Arch. f. Orthop., Mechanotherap. u. Unfallchir.*, 1913, xii, 99.

A case of recurrent luxation of the patella. NAGEOTTE-WILBOUCHEWITCH. *Arch. de méd. d. enfants, Par.*, 1913, xvi, No. 5.

Inward subastragalar luxation of the foot. EGIDI. *Riv. osp., Roma*, 1913, iii, No. 8.

Subtalar luxation of the foot. PAUS. *Norsk. mag. f. Lægevidensk.*, 1913, lxxiv, No. 5.

Surgery of the Bones, Joints, etc.

A contribution to the methods of treatment of shortening, in malunited fractures, of an extremity. B. C. PATTERSON. *Am. J. Orth. Surg.*, 1913, x, 649.

The open treatment of recent fractures according to the method of Lambotte. LENORMANT. *Presse méd.*, Par., 1913, xxi, No. 38.

Method of bone-plating. C. E. BLACK. *J. Am. M. Ass.*, 1913, lx, 1698.

Results of experiments on various bone-plates applied to fractured femora in the cadaver. E. L. ELIASON. *Therap. Gaz.*, 1913, xxxvii, 323.

The treatment of fractures of the patella. W. SAKOBIELSKI. *Arch. f. Orthop., Mechanotherap. u. Unfallchir. Wiesb.*, 1913, xii, 266.

Treatment of recent fractures of the patella. BÉRARD. *Bull. méd.*, Par., 1913, xxvii, No. 40.

Plastic surgery for the closing of bone cavities. G. PIERI. *Riv. osp.*, 1913, iii, 342.

Graftings of fat in obliteration of osteomyelitic cavities. ESTOR and ÉTIENNE. *Rev. d'orthop.*, Par., 1913, iv, No. 3.

Treatment of rachitic curvature of the tibia. ROSILADO. *Rev. ibero-amer. de cienc. med.*, 1913, xxix, No. 104.

Successful transplantation of graft without periosteum. H. G. WETHERILL. *J. Am. M. Ass.*, 1913, lx, 1533.

Partial and complete grafts of parts of joints in ulno-radio-humeral resections in animal experiments. N. PUCCI. *Clin. chir.*, Milano, 1913, xxi, 805.

Osteo-articular grafts. RAIMOLDI. *Riv. osp.*, Roma, 1913, iii, No. 8.

Arthroplasty. J. B. MURPHY. *Ann. Surg.*, Phila., 1913, lvii, 593. [297]

Osteoplasty in pseudo-arthritis of the tibia. O. VULPIUS. *Zentralbl. f. chir. u. mechan. Orthop.*, 1913, vii, 127. [299]

Further observations on the use of intra-articular silk ligaments in the paralytic joints of poliomyelitis anterior. B. BARTOW and W. W. PLUMMER. *Am. J. Orth. Surg.*, 1913, x, 499.

Operative treatment of paralyzed feet. MÜLLER. *Zentralbl. f. Chir.*, 1913, xl, No. 21.

Treatment of traumatic flat-foot. A. H. CILLEY. *Am. J. Orth. Surg.*, 1913, x, 221.

Restoring motility after bony ankylosis of the joints. R. T. TAYLOR. *N. Y. M. J.*, 1913, xcvi, 1113. [299]

Transplantation of joints obtained from cadavers. LEXER. *Deutscher chir. Kong.*, 1913. [299]

Mobilization of the ankylosed elbow-joint by free transplantation of periosteum. W. GREIFFENHAGEN. *St. Petersb. med. Ztschr.*, 1913, xxxviii, 93.

Successful arthroplastic surgery of the elbow by means of implantation of an ivory prosthesis. KÖNIG. *München. med. Wchnschr.*, 1913, lx, No. 21.

Replacement of finger and toe phalanges. W. GOEBEL. *München. med. Wchnschr.*, 1913, lx, 356. [300]

Cheilotomy: a function-restoring operation in crippling traumatic arthritis of the hip-joint. W. S. HANDLEY and C. P. BALL. *Brit. M. J.*, 1913, i, 929.

Cheilotomy for crippling traumatic arthritis of the hip-joint. W. I. D. WHEELER. *Brit. M. J.*, 1913, i, 989.

The open reduction of the congenital hip dislocation by an anterior incision. K. LUDLOFF. *Am. J. Orth. Surg.*, 1913, x, 438.

The operative treatment of snapping hip and of traumatic luxation of the ilio-tibial fimbria. WEISZ. *Monatsschr. f. Unfallheilk. u. Invalid.-Wes.*, Leipzig, 1913, xx, No. 5.

The new principle involved in resection of the knee in extensive articular affections. BOGORAS. *Arch. f. klin. Chir.*, 1913, ci, No. 1.

Conservative operative treatment of hammer toe. W. J. MERRILL. *Am. J. Orth. Surg.*, 1913, x, 262.

Supra-condylar osteoplastic amputation of the femur with retention of the supporting power of the stump. R. DALLA VEDOVA. *Riv. osp.*, 1913, iii, 337.

The formation of useful stumps in low amputations of the leg (amputation supramalleolaris) by means of the osteoplastic employment of the malleoli. LEVY. *Zentralbl. f. Chir.*, 1913, ci, No. 18.

Transplantation of tendons. W. B. LA FORCE. *Iowa M. J.*, 1913, xix, 553.

Free transplantation of periosteum: experimental investigations. SCHEPELMANN. *Arch. f. klin. Chir.*, 1913, ci, No. 2.

End results in transplantations from the dead and from a monkey. KÜTTNER. *Deutscher chir. Kong.*, 1913. [300]

The results obtained by implantation of silk tendons in the residual paralysis of poliomyelitis. N. ALLISON. *Am. J. Orth. Surg.*, 1913, x, 519.

A simple operation for the relief of the deformity in certain cases of Volkmann's paralysis. L. W. ELY. *Am. J. Orth. Surg.*, 1913, x, 201.

Primary muscular sarcoma and myomectomy. FASANO. *Policlin.*, Roma, 1913, xx, sez. chir., 86. [300]

ORTHOPEDIC SURGERY

Diseases and Deformities of the Spine

An anatomical explanation of many of the cases of weak or painful backs, as well as many of the leg paralyses. J. E. GOLDTHWAIT. *Am. J. Orth. Surg.*, 1913, x, 309.

Giant bifid spine. CHALIER and SANTY. *Rev. d'orthop.*, Par., 1913, iv, No. 3.

Absence of the cervical spine; report of a case. R. O. MEISENBACH. *Am. J. Orth. Surg.*, 1913, x, 647.

A case of spinal injury. C. W. PERKINS. *North Am. J. Homœop.*, 1913, xxviii, 274.

Traumatic hæmorrhachis. GRÉGOIRE and DESMAREST. *Paris méd.*, 1913, No. 25, May.

Traumatic spondylolisthesis following the fracture of a congenitally deficient fifth lumbar vertebra. A preliminary report. A. H. MACCORDICK and J. A. NUTTER. *Am. J. Orth. Surg.*, 1913, x, 215.

Spondilitic scoliosis. G. VECCHI. *Arch. di ortop.*, Milano, 1913, xxx, 256.

A study of the condition frequently called "sciatic scoliosis." C. H. BUCHOLZ. *Am. J. Orth. Surg.*, 1913, x, 528.

Scoliosis. A corrective jacket applied in sections. E. H. BRADFORD. *Am. J. Orth. Surg.*, 1913, x, 178.

Scoliosis and its treatment. G. BIDOU. *Paris, Maloine*, 1913.

Scoliosis and treatment of scoliosis. E. MAYER. *Med. Klin.*, 1913, ix, 662.

The treatment of scoliosis (fixed type) by plaster, supplemented by pneumatic pressure. J. P. LORD. *Am. J. Orth. Surg.*, 1913, x, 182.

The treatment of structural scoliosis. A. H. FREIBERG. *Am. J. Orth. Surg.*, 1913, x, 5.

How should we treat scoliosis caused by the malforma-

tion of the 5th lumbar vertebra? NAGEOTTE-WILBOUCHEWITCH. *Ann. de med. et chir. infant.*, Par., 1913, xvii, 302.

The old methods of treating scoliosis. RÖDERER. *Clinique*, Par., 1913, viii, No. 18.

Congenital lateral curvature of the spine. K. KANEKO. *Am. J. Orth. Surg.*, 1913, x, 396.

The correction of lateral curvature of the spine. E. G. ABBOTT. *Deutsche med. Wchnschr.*, 1913, xxxix, 892.

Vertebral osteo-arthritis. S. F. JONES. *Am. J. Orth. Surg.*, 1913, x, 363.

Laminectomy in medullary compression; thirteen operations on eleven patients; one case of complete recovery. A. VAN GEHUCHTEN and A. LAMBOTIE. *Nevraxe*, 1913, xiii, 319.

Fracture of the arch of the seventh cervical vertebra by a blow with a fire-arm, associated with a hemorrhagic focus in the spinal cord. MACNINI. *Policlin.*, Roma, 1913, xx, No. 5.

Pseudo-fractures of transverse processes. O. L. RHYS. *Brit. M. J.*, 1913, i, 1103.

Subluxation of the lumbosacral joint as a cause of paraplegia; report of a case; recovery after manipulation. R. R. FITCH. *Am. J. Orth. Surg.*, 1913, x, 587.

Caudal tumors. O. BRUNS. *Fortschr. d. Med.*, 1913, xxxi, 393.

Diagnosis of tumors of the spinal cord. JANCKE. *München. med. Wchnschr.*, 1913, lx, No. 19.

Suffuse subdural lipomatosis of the spinal cord in an infant. S. B. WOLBACH and J. A. P. MILLETT. *Boston M. & S. J.*, 1913, clxviii, 681.

Removal of intrathecal tumor from lumbar region of spinal cord. J. M. CLARKE and C. A. MORTON. *Brit. M. J.*, 1913, i, 932.

Brown-Sequard's traumatic syndrome. LONG and JUMENTIE. *Informat. d. alien. et d. neurol.*, 1913, viii, 100.

A preliminary note from an experimental investigation of concussion of the spinal cord and allied conditions. A. NEWTON. *Brit. M. J.*, 1913, i, 1101.

The present and future of spinal cord surgery. ROTHMANN. *Berl. klin. Wchnschr.*, 1913, l, 528. [301]

Surgery of the spinal cord. RANZI. *Deutscher chir. Kong.*, 1913. [301]

Surgery of the spinal column and the spinal cord. POTEL and VEAUDEAU. *Rev. de chir.*, Par., 1913, xxxiii, No. 5.

Operations on the spinal cord and the nerves for paraplegia, spastic paralysis, and neuralgia, and for the treat-

ment of neuritis and nocturnal enuresis. TIMOFEIFF. *Voenno-med. J.*, St. Petersburg, 1913, cckxxvi, May.

The treatment of tabetic gastric crises by Foersters-Guleck operation. NASTA. *Revista de chir.*, 1913, i, 20. [301]

The operative treatment of lues of the central nervous system. SCHOENBORN. *Zentralbl. f. d. Grenzgeb. d. Med. u. Chir.*, 1913, xvi, No. 5.

The therapeutic value of lumbar puncture. L. LOURIA. *Long Island M. J.*, 1913, vii, 169.

Malformations and Deformities

Congenital malformations caused by amniotic remnants. OMBREDANNE. *Rev. d'orthop.*, Par., 1913, iv, No. 3.

The causation and treatment of deformities following anterior poliomyelitis. B. P. CAMPBELL. *Edinb. M. J.*, 1913, x, 390.

A case of congenital bilateral defect of the radius. A. LORENZ. *Wien. med. Wchnschr.*, 1913, lxiii, 1052.

A case of double congenital coxa valga associated with subluxation on one side. LANCE. *Rev. d'orthop.*, Par., 1913, iv, No. 3.

The pathology and therapy of congenital dislocations of the hip. R. WERNDORFF. *Am. J. Orth. Surg.*, 1913, x, 243.

Deformities of the thigh developing after reduction of congenital luxations of the hip-joint. M. HORVATH. *Beitr. z. klin. Chir.*, 1913, lxxiv, 27.

Treatment of congenital dislocation of the hip. A. S. B. BANKART. *Brit. M. J.*, 1913, i, 1044.

Absence of the bony femoral heads and necks. J. RIDLON and H. B. THOMAS. *Am. J. Orth. Surg.*, 1913, x, 205.

Report of a case of total congenital absence of the femur. J. J. THOMAS. *Cleveland M. J.*, 1913, xii, 321. [302]

Congenital anterior subluxation of the knee. L. MAYER. *Am. J. Orth. Surg.*, 1913, x, 411.

Congenital absence of the fibula. P. LE BRETON. *Am. J. Orth. Surg.*, 1913, x, 408.

Talipes equinus deformity. E. W. HANNOCK. *Am. J. Surg.*, 1913, xxvii, 194. [302]

Flat-foot. K. CRAMER. *Arch. f. Orthop., Mechano-therap. u. Unfallchir.*, 1913, xii, 1.

Spontaneous gangrene and allied conditions in orthopedic surgery. W. G. STERN. *Am. J. Orth. Surg.*, 1913, x, 381.

SURGERY OF THE NERVOUS SYSTEM

A case of facio-hypoglossal anastomosis. E. C. REVERS. *Lancet*, Lond., 1913, clxxxiv, 1450.

Regenerative phenomena in the healing of motor and sensory nerve fibers. J. BOCKE. *Anat. Anz.*, Jena, 1913, xliii, 366.

Acute posterior ganglionitis simulating surgical conditions in the abdomen. L. LITCHFIELD. *J. Am. M. Ass.*, 1913, lx, 1691.

The treatment of tendo- and neurolysis with transplantations of fatty tissue. EDEN. *Deutscher chir. Kong.*, 1913. [301]

A case of paralysis of the external popliteal nerve following nodular erythema. PROCHEZKA. *Čas. lék. česk.*, Prague, 1913, lii, No. 16.

The treatment of neuralgia by injections (intraspinal injections, subcutaneous injections, intraneural injections). RIMBAUD and GRASSET. *Montpellier méd.*, Par., 1913, xxxvi, No. 20.

Neuroma of the ulnar nerve. JABOULAY. *Progrès méd.*, Par., 1913, xli, No. 20.

Malignant neuroma of the ulnar nerve. NOVÉ-JOSSE-RAND, SAVY and MARTIN. *Province méd.*, Par., 1913, xxvi, No. 21.

Traumatic section of the ulnar nerve at the posterior surface of the arm; immediate suture; restoration of function forty-eight hours after the suture; partial persistence of anaesthesia; secondary atrophy of the interosseous muscles and of the hypothenar eminence; integrity of the flexor muscles; functional results satisfactory. MIGINIAC. *Gaz. d. hôp.*, Par., 1913, lxxvi, No. 54.

The indications and results of the excision of posterior spinal nerve roots in men. FOERSTER. *Surg., Gynec. & Obst.*, 1913, xvi, 463. [302]

A case of spastic paralysis treated by Foerster's and Stoffel's operations. BILLMAN. *Ugesk. f. Laeger*, Kjøbenhavn, 1913, lxxv, No. 17.

DISEASES AND SURGERY OF THE SKIN, FASCIA, APPENDAGES

The abuse of the X-rays in the treatment of skin affections. J. T. BOWEN. Boston M. & S. J., 1913, clxviii, 682.

Erysipelas and tattooing. E. SEHRWALD. München. med. Wchnschr., 1913, lx, 976.

Treatment of erysipelas. F. S. ARNOLD. Practitioner, Lond., 1913, xc, 900.

Tuberculosis of the skin. LINSER. Med. Cor.-Bl. d. württemb. ärztl. Ver., Stuttg., 1913, lxxxiii, 313.

Extensive tuberculosis cutis with death from pyæmia; report of a case. H. K. GASKILL. J. Cutan. Dis., 1913, xxxi, 309.

The treatment of lupus. SCHOLTZ. Ztschr. f. ärztl. Fortbild., 1913, x, 193. [303]

Cutaneous gangrene. E. GREGGIO. Gazz. internaz. di med., chir., ig., Napoli, 1913, No. 14, 313.

Current methods of treating furuncles. ROZIES. Progrès méd., Par., 1913, xli, No. 20.

A new method of treating furuncles in the initial stage. HERRILD. Ugesk. f. Laeger, Kjøbenh., 1913, lxxv, No. 19.

The general pathological significance of dermatomycoses. B. BLOCH. Samml. zwangl. Abh. a. d. Geb. d. Dermat., d. Syphilidol. u. d. Krankh. d. Urogenitalapp., 1913, ii, 5.

Primary cutaneous sarcomatosis secondary to a punctured wound of the skin. FAVRE and SAVY. Lyon méd., 1913, cxx, No. 20.

The combined treatment of cutaneous carcinoma by carbon dioxide freezing and Röntgen-rays. J. FABRY. Arch. f. Dermat. u. Syph., Wien, 1913, cxvi, 389.

Treatment of cutaneous epitheliomata by the mixed method (scraping and radiotherapy). BELOT and DU-BOIS-HAVENITH. J. de radiol., Brux., 1913, vii, No. 1.

Pathology and treatment of hæmangioma cavernosum. M. M. PATTON. Northwest Med., 1913, v, 119.

In how far are newly ruptured varicose ulcers to be considered as an immediate consequence of an accident? FRANCK. Monatschr. f. Unfallheilk. u. Invalid.-Wes., Leipz., 1913, xx, No. 4.

Varicose ulcers and heated air. ROZIER. Sud méd., Marseilles, 1913, xlii, No. 1960.

Treatment of varicose ulcers by the modified Moreschi method. CHARRIER and BARDON. J. de méd. de Bordeaux, 1913, xliii, No. 18.

Basic fuchsin in chronic leg ulcer; a preliminary report. E. S. MAY and M. L. HEIDINGSFELD. J. Am. M. Ass., 1913, lx, 1680.

The technique of transplantation of fasciæ. GULEKE. Zentralbl. f. Chir., 1913, xl, 683.

The transplantation of rib cartilage into pedunculated skin flaps. J. S. DAVIS. Urol. & Cutan. Rev., 1913, xvii, 233.

Skin-grafting without dressings. JOS. WIENER. J. Am. M. Ass., 1913, lx, 1526. [303]

MISCELLANEOUS

Clinical Entities—Tumors, Ulcers, Abscesses, etc.

Fundamental problems of the theory of tumors. B. FISCHER. Frankf. Ztschr. f. Pathol., 1913, xii, 367.

Summary of investigations in tumor growth. L. LOEB. Interst. M. J., 1913, xx, 398.

Recent investigations on tumors. M. LISSAUER. Med. Klin., 1913, ix, 420. [304]

Hereditary predisposition to tumor formation. B. MORPURGO and A. DONATI. München. med. Wchnschr., 1913, lx, 626.

The artificial culture of human tumors. ALBRECHT and LOANOVICS. Wien. klin. Wchnschr., 1913, xxvi, No. 20.

The nomenclature of tumors. VON HANSEMAN. Ztschr. f. Krebsforsch., Berl., 1913, xiii, No. 2.

Malignant tumors of the African natives. LEGRAIN. Rev. suisse de méd., 1913, No. 15.

Paraffin tumors. A. N. SARAP. Voienno-med. J., St. Petersb., 1913, ccxxvii, 568.

The line of advance at present open in connection with cancer. J. M. WAINWRIGHT. Internat. J. Surg., 1913, xxvi, 152.

Newer ideas concerning the problem of cancer etiology. L. D. BRISTOL. Med. Rec., 1913, lxxxiii, 787. [304]

Comparative studies upon cancer cells and normal cells. II. The character of growth in vitro with special reference to cell division. R. A. LAMBERT. J. Exp. M., 1913, xvii, 499. [305]

Current methods of diagnosis of cancer. DUKER. Nederl. Tijdschr. v. Geneesk., 1913, i, No. 9.

Experimental production of a cancer and its lessons. C. FIRKET. Scalpel et Liege med., 1913, lxxv, 705.

The prevention and cure of cancer. P. SYMS. Med. Rec., 1913, lxxxiii, 881.

The vitality and development of transplanted cancerous tissue and the biochemistry of the cancerous area. SPINELLI. Arch. ital. di ginec., Napoli, 1913, xvi, No. 4.

Disappearance of secondary carcinoma without extirpation. H. LILIENTHAL. Internat. J. Surg., 1913, xxvi, 156.

The forms of carcinoma prevalent in Norway. SOEGAARD. Ztschr. f. Krebsforsch., Berl., 1913, xiii, No. 2.

Cancer mortality in Prussia during the years 1903-11, classified according to age. R. BEHLA. Berl. klin. Wchnschr., 1913, l, 882.

Cancer as a surgical problem. J. W. KENNEDY. Med. Council, 1913, xviii, 212.

The surgical treatment of cancer. W. S. BAINBRIDGE. Internat. J. Surg., 1913, xxvi, 143.

On the treatment of epithelioma. A. RAVOGLI. Am. J. Surg., 1913, xxvii, 173.

Dyspeptic coma and cancerous coma. CADE and ROUBIER. Arch. d. mal. de l'appar. digest. et de la nutrition, Par., 1913, vii, No. 4.

Multiple brown tumors in osteomalacia. MOLINEUS. Arch. f. klin. Chir., Berl., 1913, ci, No. 2.

Myeloma. SISOEFF. Chir. arch. Veliaminova, St. Petersb., 1913, xxix, No. 2.

Researches on sarcosporidia. I. A morphological study. A. ALEXEIEFF. Arch. d. zool. exp. et gén., Par., 1913, li, 521.

Mycetoma in America. R. L. SUTTON. J. Am. M. Ass., 1913, lx, 1339. [305]

Benign melanosis; a supplementary report. J. C. STEWART. J. Am. M. Ass., 1913, lx, 1358.

The control of rabies. H. ALBERT. Am. J. M. Sc., 1913, cxlv, 697.

Reclus' lignous phlegmon. NAKAMURA. Jundendo Ijikenku Kwai Hoko, Tokyo, 1913, No. 482.

The identity of cause of aseptic wound fever and so-

called post-operative hyperthyroidism, and their prevention. G. W. CRILE. *Ann. Surg., Phila.*, 1913, lvii, 648. [305]

Right-of-way vs. hospital treatment of surgical shock. O. F. SCOTT. *Chicago M. Recorder*, 1913, xxxv, 257.

Anthrax. SCHULTZE. *Ärzt. Sachverst.-Ztg.*, 1913, xix, 211.

Tetanus. Three cases with recovery. E. C. HENRY. *Med. Council*, 1913, xviii, 166.

Post-operative cases of death in abnormal narrowing of the aorta. FRÜHWALD. *Deutsche med. Wchnschr.*, 1913, xxxix, No. 19.

Pre-operative determination of the powers of resistance of the patients. DE GRAEUWE. *J. de chir.*, 1913, x, 433.

Complications following surgical operations. E. H. BECKMAN. *Ann. Surg., Phila.*, 1913, lvii, 718.

A peculiar action of foreign bodies. SULTAN. *München. med. Wchnschr.*, 1913, lx, No. 19.

Sera, Vaccines and Ferments

The complement fixation test in the diagnosis of gonorrhoea. R. G. OWEN and H. SNURE. *J. Mich. St. M. Soc.*, 1913, xii, 247.

Serodiagnosis of tumors by the deviation of the complement. J. HALPERN. *München. med. Wchnschr.*, 1913, lx, 914.

Abderhalden's serum test for carcinoma. EPSTEIN. *Wien. klin. Wchnschr.*, 1913, xxvi, No. 17.

Serodiagnosis of carcinoma. ROSENBERG. *Deutsche med. Wchnschr.*, 1913, xxxix, No. 20.

Clinical value of tuberculin in diagnosis and treatment. W. J. DUREL. *Southern M. J.*, 1913, vi, 303.

The use of tuberculin in diagnosis and treatment. J. F. H. DALLY. *Lancet, Lond.*, 1913, clxxxiv, 1228.

Plea for uniform method of treatment with tuberculin. J. H. THOMSON. *Brit. M. J.*, 1913, i, 926.

The present evidence for and against the use of tuberculin as a specific cure. H. B. SHAW. *Brit. M. J.*, 1913, i, 921.

The treatment of infantile tuberculosis by Rosenbach's tuberculin. C. BECK. *Ztschr. f. Kinderh.*, 1913, vi, 439.

Hypersensitiveness to tuberculo-protein and to tuberculin. C. R. AUSTRIAN. *Bull. Johns Hopkins Hosp.*, 1913, xxiv, 141. [306]

Treatment of erysipelas with antimeningococcus serum. WELZ. *Therap. Monatsh.*, 1913, xxvii, 273.

A method for standardizing bacterial vaccines. J. G. HOPKINS. *J. Am. M. Ass.*, 1913, lx, 1615.

An attempt to interpret present-day uses of vaccines. T. SMITH. *J. Am. M. Ass.*, 1913, lx, 1591.

Clinical observation on the effect of gonococci vaccine in chronic gonorrhoeal arthritides. SEMENEW. *Ztschr. f. Urol., Berl.*, 1913, vii, No. 5.

Gonargin, a new vaccine preparation. J. SCHUMACHER. *Dermat. Ztschr., Berl.*, 1913, xx, 400.

Vaccinotherapy in bacteraemia. SORMANI. *Nederl. Tijdschr. v. Geneesk.*, 1913, i, No. 15.

A note on the use of vaccines in the treatment of rheumatoid arthritis. A. B. SOLTAU. *Lancet, Lond.*, 1913, clxxxiv, 1379.

Is specificity of anaphylaxis reaction dependent on chemical constitution of proteins or on their biologic relations? H. G. WELLS and T. B. OSBORNE. *J. Infect. Dis.*, 1913, xii, No. 3.

Blood

The relations of the thymus and ovary to the blood picture. HEIMANN. *Deutsche Gesellsch. f. Gynäk., Halle*, 1913, May. [306]

The laws of the activity of the leucocytes in inflammatory processes. M. LÖHLEIN. *Fischer: Jena*, 1913.

Investigation on analysis of the blood in struma and the effect of thyroidectomy on the constitution of the blood. E. NAGELSBACH. *Beitr. z. klin. Chir.*, 1913, lxxxiii, 489.

A case of very severe melæna of the new-born, cured by injection of defibrinated human blood. MERCKENS. *München. med. Wchnschr.*, 1913, lx, No. 18.

Some details of the venous circulation. E. SCHULTZE. *Med. Fortnightly*, 1913, xliii, 169.

The occurrence of tubercle bacilli in the blood. BACMESITER. *Zentralbl. f. d. Grenzgeb. d. Med. u. Chir.*, 1913, xvi, No. 5.

The value of polymorph neutrophile leucocytes in disease; with special reference to vaccine treatment in tuberculosis. E. H. BLACK. *J. Clin. Research*, 1913, vi, 39.

Two cases of traumatic leucæmia. FACCHINI. *Gazz. d. osp. e d. clin., Milano*, 1913, xxxiv, No. 60.

Hæmolytic icterus. ANTONELLI. *Policlin., Roma*, 1913, xx, No. 5.

A method of controlling rectal hæmorrhages. B. L. MYERS. *J. Am. M. Ass.*, 1913, lx, 1619.

Control of internal hæmorrhages by means of intravenous injection of grape sugar. SCHREIBER. *Therap. d. Gegenw.*, Berl., 1913, liv, No. 3.

Successful treatment of hæmophilic hæmorrhages by means of thermocauterization. PARREIDT. *München. med. Wchnschr.*, 1913, lx, No. 21.

Hæmorrhagic conditions of children. SORESI. *Arch. Pediat.*, 1913, xxx, 252. [306]

Blood coagulation; physico-chemical processes and their relation to the action of thrombin. M. LANDSBERG. *Biochem. Ztschr.*, 1913, l, 245.

Technique and results of my method of determining the lapse of time in blood coagulation. W. SCHULTZ. *München. med. Wchnschr.*, 1913, lx, 4.

Remedial agents which specifically check coagulation and decrease the blood pressure in the female genitalia. L. POPIELSKI. *Biochem. Ztschr.*, 1913, xlix, 168. [307]

Thrombophlebitis of the external iliac vein. M. LEALE. *J. Am. M. Ass.*, 1913, lx, 1523. [307]

Thrombosis of the portal vein following the effect of blunt force to the abdomen. ENDERLEN. *Beitr. z. klin. Chir.*, 1913, lxxxiii, 726. [307]

Traumatic thrombosis of the veins of the upper arm. BAUM. *Deutsche med. Wchnschr.*, 1913, xxxix, No. 21.

Thrombosis and embolisms after gynecological operations. T. VON WENZEL. *Beitr. z. klin. Chir.*, 1913, lxxxiv, 37.

A case of embolism of the abdominal aorta. SCHIRMAN. *Pract. Vrach*, 1913, xii, 244.

Air embolism. W. F. RICE. *Hosp. Bull. Univ. Md.*, 1913, ix, 47.

Relation of gas embolism to production of artificial pneumothorax. S. T. HARRIS. *Southern M. J.*, 1913, vi, 309.

Embolism by adipose tissue in the large blood circuit and its cause. C. FROMBERG and F. NAVILLE. *Mitt. a. d. Grenzgeb. d. Med. u. Chir.*, 1913, xxvi, 23.

Direct transfusion for hæmorrhagic purpura. W. L. DUFFIELD. *Long Island M. J.*, 1913, vii, 188.

A case of direct transfusion of blood by end-to-end suture of the radial artery to the basilic vein. A. JACOMET. *Bull. méd., Par.*, 1913, xxvii, 435.

Experimental, agglutinative, and hæmolytic transfusions. OTTENBERG, KALISKI and FRIEDMAN. *J. Med. Research*, 1913, xxviii, 141. [307]

Blood and Lymph Vessels

The relation of vascular conditions to pituitrin diuresis. R. G. HOSKINS and J. W. MEANS. *J. Pharmacol. & Exp. Therapeut.*, 1913, iv, 435.

Cirroid aneurism of the hand. M. BALLIN. J. Mich. St. M. Soc., 1913, xii, 265. [308]

A case of abdominal aneurism with unusual features, operated on by means of Colt's apparatus. J. R. COLLINS and C. BRAINE-HARTNELL. Brit. M. J., 1913, i, 987.

Tuberculosis of the large arteries; with the report of a case of tuberculous aneurism of the right iliac artery. S. R. HAYTHORN. J. Am. M. Ass., 1913, lx, 1413. [308]

Primary tumors of the vascular sheaths. FERRARINI. Clin. chir., 1913, xxi, 589. [308]

Cold gangrene due to vascular paralysis. WIETING. Zentralbl. f. Chir., 1913, xl, 593. [309]

Pneumococcic phlebitis and precocious phlebitis of tuberculous patients. LAFFORGUE. Progrès méd., Par., 1913, xli, No. 18.

The present status of vascular surgery. DUMONT. Cor.-Bl. f. Schweiz. Ärzte, 1913, xliii, No. 20.

Circular suture of the vessels. M. HIRSCH. Wien. med. Wchnschr., 1913, lxiii, 1233.

Repair of the abdominal aorta by the carotid artery of the same animal. JEGER and JOSEPH. Arch. f. klin. Chir., 1913, ci, No. 2.

The operative treatment of varicose veins of the lower limbs. ORLOFF. Voenno-med. J., St. Petersburg, 1913, ccxxvi, Mar.

Experimental ligation of the portal vein; its application to the treatment of suppurative pyelphlebitis. H. NEUHOF. Surg., Gynec. & Obst., 1913, xvi, 481. [309]

Investigations on the transplantation of blood vessels. CASTIGLIONI. Beitr. z. path. Anat. u. z. allg. Path., 1913, lvi, 63.

Researches on the transplantation of veins into the ureter. CUTURI. Riforma méd., 1913, xxix, No. 17.

Intravenous injections. FRIEDMANN. München. med. Wchnschr., 1913, lx, No. 19.

The etiology and preventive inoculation of elephantiasis. JOSHINAGA. Ken-Yo-Kai-Zasshi, 1913, No. 109. [309]

Intradermic lymphangiectases in the inguinocrural region. JACOB. Bull. et mém. Soc. de chir. de Par., 1913, xxxix, 606.

Endothelioma of lymph nodes. J. EWING. J. Med. Research, 1913, xxviii, 11. [310]

A further contribution on the question of permanent subcutaneous drainage in dropsy. W. PERIMOFF. Kazan. med. Ztschr., 1913, xiii, 59.

Poisons

A method of counting bacteria in water. Remarks upon the bearing of the method upon the subject of "Saline Fever" by Paul Fildes. R. DONALD and P. FILDES. Lancet, Lond., 1913, clxxxiv, 1447.

Re-infection. LÖHE. Berl. klin. Wchnschr., 1913, l, No. 20.

A case of acute septicæmia due to the B. pyocyaneus. M. CLARKE. Med. Press & Circ., 1913, cxlvi, 492.

A bacillus of an unusual kind isolated from a case of septicæmia. J. A. B. HICKS. Lancet, Lond., 1913, clxxxix, 1526.

Tetanus bacilli and tetanus toxin. H. E. BEESER. Folia microbiol., 1913, ii, 66.

Is the tetanus bacillus gram-positive? H. EYMER. Zentralbl. f. Bakteriologie, 1913, lxix, 1.

The micrococcus tetragenous as a cause of bacteriæmia in the human. STROBEL. Beitr. z. klin. Chir., 1913, lxxxiii, 718. [310]

Treatment of acute surgical infections with rhythmical hyperæmia. THIES. Deutscher chir. Kong., 1913. [311]

Surgical Therapeutics

Further reports on KJ. (1) Its action on cancerous tumors; (2) as a cure for these in combination with subcutaneous injections of 0.5 per cent natrium arsenicum in 0.25 per cent carbolic solution. MICHALOW. Russk. Vrach, St. Petersburg, 1913, xii, 423.

The treatment of septic processes by the administration of alkalies. VORSCHÜTZ. Deutscher chir. Kong., 1913. [311]

On the value of peristaltin in the after-treatment of laparotomy patients. VON BRUNN. Zentralbl. f. Chir., 1913, xl, 431. [311]

A case of tetanus treated with intraspinal injections of magnesium sulphate. H. L. TIDY. Brit. M. J., 1913, i, 1104.

The influence of morphine, opium and pantopon on the movements of the gastro-intestinal tract in man and in animals. N. SCHAPIRO. Arch. f. d. ges. Physiol., 1913, cli, 65.

The iodine treatment and dechloruration. F. SARVONAT and R. CRÉMIEU. Province méd., Par., 1913, xxvi, 184.

A new powder for wounds. F. HAMMER. München. med. Wchnschr., 1913, lx, 1150.

Styptics, with special consideration of erystipticum "Roche." A. GISEL. Deutsche med. Wchnschr., 1913, xxxix, 1046.

Noviform, a new substitute for iodoform in surgery. FRICHBERG. Novoié v med., St. Petersburg, 1913, vii, No. 7.

Treatment of wounds with sugar. G. MAGNUS. München. med. Wchnschr., 1913, lx, 406. [311]

Therapeutic experiments with local thorium chloride treatment in carcinomatous mice and sarcomatous rats. CAAN. München. med. Wchnschr., 1913, lx, No. 20.

Balsam of Peru: a historical note. J. KNOTT. Med. Press & Circ., 1913, cxlvi, 521.

Treatment of cancer by sulphate of quinide. CASTAGNE. Ann. de chir. et d'orthop., Par., 1913, xxvi, 80.

Treatment of superficial new growths by pure radium bromide. F. H. WILLIAMS and S. W. ELLSWORTH. J. Am. M. Ass., 1913, lx, 1694.

The results obtained with the employment of fibrolysin in cicatrization. G. WERDNIGG. Klin.-therap. Wchnschr., 1913, xx, 607.

The effect of collargol clysters in septic processes. WOLF. Deutsche med. Wchnschr., 1913, xxxix, No. 20.

The diuretic action of extracts of the hypophysis. L. LUCATELLO. Gazz. d. osp. e d. clin., Milano, 1913, xxxiv, 393.

Report on the use of pituitary extract in surgical shock. C. A. HILL. Boston M. & S. J., 1913, clxviii, 720. [311]

Surgical Anatomy

The skeleton of a pseudo-hermaphrodite. W. WALDEYER. Sitzungsber. d. k.-preusz. Akad. d. Wiss., Berl. 1913, xx, 368.

Some observations on the anatomy of the inguinal region, with special reference to absence of the conjoined tendon. W. HESSERT. Surg., Gynec. & Obst., 1913, xvi, 565. [312]

Electrology

What the X-ray should mean to the physician. G. D. BOND. Tex. St. J. Med., 1913, ix, 19.

X-ray diagnosis of post-operative affections. BUSSE. Deutsche Gesellsch. f. Gynäk., Halle, 1913, May.

Clinical factors in X-ray work. A. W. CRANE. J. Mich. St. M. Soc., 1913, xii, 263.

Researches on the action of Röntgen rays on living tissues and their therapeutic applications. HURTADO. *Rev. ibero-amer. de cienc. med.*, Madrid, 1913, xxix, No. 104.

Histological changes produced in the tissues by the action of rays. WICKHAM. *Arch. d'électr. méd., exp. et clin.*, Bordeaux, 1913, xxi, No. 358.

Progress in the field of röntgenotherapy during the last year. H. E. SCHMIDT. *Berl. klin. Wchnschr.*, 1913, l, 927.

A new device in X-ray tubes rendering the diaphragm unnecessary. S. TOUSEY. *Arch. Röntg. Ray*, 1913, No. 154, 473.

The present status of röntgenotherapy. N. DOHAN. *Wien. med. Wchnschr.*, 1913, lxiii, 935.

Critical contributions on the study of deep röntgenotherapy. KRAUSE. *Fortschr. a. d. Geb. d. Röntgenstr.*, 1913, xx, No. 2.

A case of tardy injurious effects of deep röntgenotherapy. DIETERICH. *Fortschr. a. d. Geb. d. Röntgenstr.*, 1913, xx, No. 2.

Experiments with hard Röntgen rays. F. M. GRÖDEL. *München. med. Wchnschr.*, 1913, lx, 1090.

Experiments with hard Röntgen rays, and special considerations on deep radiology. F. DESSAUER. *München. med. Wchnschr.*, 1913, lx, 696.

A handbook on instantaneous photography in röntgenotherapy. J. SCHWENTER. Leipzig, 1913.

Radiotherapy for tumors. WERNER. *Zentralbl. f. Gynäk.*, 1913, xxxvii, 601.

Radiotherapy of malignant tumors. R. JEDLICKA. *Ann. d'électrobiol. et de radiol.*, 1913, xvi, 263.

Treatment of deep-seated cancer by X-rays excited by a current of unfluctuating voltage. S. TOUSEY. *Internat. J. Surg.*, 1913, xxvi, 169.

The biochemical action of rays, with special consideration of the Röntgen rays. BORDIER. *Fortschr. a. d. Geb. d. Röntgenstr.*, 1913, xx, No. 2.

The radiographic diagnosis of syphilis, tuberculosis tumors and osteomyelitis of the long bones. W. M. BRICKNER. *Am. J. Surg.*, 1913, xxvii, 165.

The radioactive substances of the thorium series in therapeutics. LEDOUXLEBARD. *Arch. d'électr. méd., exp. et clin.*, Bordeaux, 1913, xxi, No. 358.

The new radium and thorium therapy. F. H. BLACKMAR. *Med. Times*, 1913, xli, 135.

Radium emanation therapy. W. ENGELMANN. *Lancet*, Lond., 1913, clxxxiv, 1225.

Radium in dermatology. W. H. B. AIKENS and F. C. HARRISON. *Canad. Pract. & Rev.*, 1913, xxxviii, 255.

The employment of radium in surgery. A. STICKER. *Arch. f. physikal. Med. u. med. Techn.*, 1913, vii, 182. [312]

Treatment by radium in post-operative relapse of sarcoma. HARET. *J. de radiol.*, Brux., 1913, vii, No. 1.

The use of radiography in surgical affections of the stomach and intestines. BÉCLÈRE and MÉRIEL. 25th Cong. d. l'Ass. Fran. d. Chir., 1912, Oct. [312]

The bactericid action of ultra-violet light in clear, turbid and colored water. M. OLER-BLOM. *Ztschr. f. Hyg. u. Infektionskrankh.*, 1913, lxxiv, 197.

Heliotherapy. E. ESTOR. *Ann. de méd. et chir. infant.*, Par., 1913, xvii, 289.

Chromoendophotography. ILGNER. *Deutsche Ges. f. Gynäk.*, Halle, 1913.

The aërothermic treatment; personal statistics. COLOMB. *Marseille méd.*, 1913, l, No. 10.

Military and Naval Surgery

Military surgery. G. M. BLECH. *Am. J. Surg.*, 1913, xxvii, 184.

Experiences in military surgery. P. CLAIRMONT. *Wien. klin. Wchnschr.*, 1913, xxvi, 613.

The action of bullets. TILE. *Chir. arch. Veliaminova*, St. Petersburg, 1913, xxix, No. 2.

Gun-shot injuries of blood vessels. LOTSCH. *Deutsche chir. Kong.*, 1913. [313]

Gun-shot injuries in civil practice. N. A. POWELL. *Canad. J. M. & S.*, 1913, xxxiii, 324.

Wounds by modern fire-arms. PHOCAS. *Bull. et mém. Soc. de chir. de Par.*, 1913, xxxix, 614.

Air contusions caused by passing projectiles; based on experiences of the war of 1904-1905. G. E. SCHUMKOW. *Volenno-med. J.*, St. Petersburg, 1913, ccxxxvi, 192.

Experiences with the mastisol dressing in the Serbo-Turkish war. STIERLIN and VISCHER. *Cor.-Bl. f. Schweiz. Ärzte*, 1913, xliii, No. 19.

GYNECOLOGY

Uterus

Investigations of the endometrium; the histologic changes incident to benign affections of the endometrium corporis. S. KJÆGAARD. *Kjøbenh.*, 1913. [314]

The cells of the myometrium which take up the carmine in physiological injections. P. BOUIN and P. ANCEL. *Compt. rend. hebdom. Soc. de biol.*, Par., 1913, lxxiv, 728.

The blood vessels of the uterus during the menopause. SUDAKOFF. *J. akush. i. jensk. boliez.*, St. Petersburg, 1913, xxviii, 589. [314]

A voluminous calculus which enclosed the uterus and simulated a neoplasm. ROMEO. *Gazz. d. osp. e d. clin.*, Milano, 1913, xxxiv, 536.

Cancer of the uterus. R. M. RAWLS. *Med. Rec.*, 1913, lxxiii, 892. [315]

Clinical study of uterine cancers observed in the gynecological consulting room of the inclusion. LIZCANIO. *Siglo med.*, Madrid, 1913, lx, No. 3101.

Statistical contribution on uterine carcinoma. OBATA. *Arch. f. Gynäk.*, 1913, xcix, No. 3.

Some observations on carcinoma of the uterus. S. W. BANDLER. *Internat. J. Surg.*, 1913, xxvi, 159.

Operative indications in cancer of the uterus. J. L. FAURE. *Arch. mens. d'obst. et de gynec.*, 1913, ii, 324.

The present status of the radical abdominal operation for cancer of the uterus. R. PETERSON. *Surg., Gynec. & Obst.*, 1913, xvi, 561. [315]

Non-surgical treatment of cancer. A. THEILHABER. *Berl. klin. Wchnschr.*, 1913, l, 348. [315]

X-ray treatment in carcinoma of the uterus, of the mammary gland, and of the ovaries. G. KLEIN. *München med. Wchnschr.*, 1913, lx, 905.

Diffuse adenomyomatosis of uterus and rectum. E. FORGUE and G. MASSABEAU. *Paris méd.*, 1913, ii, No. 22.

Data furnished by the cystoscopic exploration in cancer of the cervix. HARTMANN. Paris méd., 1913, ii, No. 22.

Marked influence of mesothorium raying on a cervical cancer. S. MEIDNER. Therap. d. Gegenwart, 1913, liv, 149. [316]

The cautery in the radical treatment of cancer of the cervix. WERDER. Surg., Gynec. & Obst., 1913, xvi, 579. [316]

Benign invasion of the uterus and oviducts by chorio-epithelial elements. F. DAELS. Bull. Acad. roy. de méd. de Belg., Brux., 1913, xxvii, 198.

Myomatous uterus associated with bilateral inflammation of the adnexa and left pyovarium. WEINBRENNER. München. med. Wchnschr., 1913, lx, 1232.

Röntgenotherapy in myomata and fibrosis of the uterus. HIRSCH. München. med. Wchnschr., 1913, lx, No. 17.

Fibromyoma uteri. W. P. HEALY. N. Y. M. J., 1913, xxviii, 922.

Röntgenotherapy of uterine fibromyomata. CALATAYUD. J. de radiol., Brux., 1913, vii, No. 1, and Rev. espan. de electr. y radiol. méd., Valencia, 1913, ii, No. 14.

Organotherapy for menstrual troubles and uterine fibromyomata. WIJN. Nederl. Tijdschr. v. Geneesk., Amst., 1913, i, No. 12.

Etiology and treatment of uterine hæmorrhages. L. HIRSCH. Monatschr. f. Geburtsh. u. Gynäk., 1913, xxxvii, 420. [317]

Sclerosis of the uterus (arteriosclerosis uteri) and its relation to uterine hæmorrhages. BUKOJEMSKY. Arch. f. Gynäk., Berl., 1913, xcix, No. 3.

Treatment of metritis by high-frequency current electric curettement. P. COTTENOT. Bull. off. Soc. franç. d'électrothérap. et de radiol., 1913.

The treatment of dysmenorrhœa. M. GOLDSCHMIDT. Fortschr. d. Med., Berl., 1913, xxxi, 546.

The treatment of pseudo-membranous dysmenorrhœa. A. F. PLICQUE. Bull. méd., Par., 1913, xxvii, 416.

Treatment of amenorrhœa. FRIES. Deutsche med. Wchnschr., 1913, xxxix, 675. [317]

Practical application of electricity as a therapeutic agent. Amenorrhœa, dysmenorrhœa, and hæmatocele. J. R. ETTER. Med. Summary, 1913, xxxv, 69.

Uterine hæmorrhage and its treatment. F. A. HARPER, Med. Council, 1913, xviii, 173.

Medicinal treatment of uterine hæmorrhages. G. KATZ. Med. Klin., 1913, ix, 670.

Uterine hæmorrhages and the electric treatment. MARTIN. Sud méd., Marseille, 1913, xlvii, No. 1960.

X-ray therapy in uterine hæmorrhage. A. FOGES. Wien. med. Wchnschr., 1913, lxiii, 995. [317]

The treatment of uterine hæmorrhage by means of the Röntgen rays. G. E. PFAHLER. Am. J. Obst., N. Y., 1913, lxvii, 860. [317]

X-ray therapy or vaporization in the treatment of hæmorrhagic metropathys. FUCHS. Monatschr. f. Geburtsh. u. Gynäk., 1913, xxvii, 496. [318]

Surgical treatment of uterine hæmorrhage from the non-pregnant uterus. W. KRUSEN. Am. J. Obst., N. Y., 1913, lxvii, 885.

The operative treatment of cervical dropsy. VENGLOVSKY. Chir. arch. Veliaminova, St. Petersburg., 1913, xxix, No. 2.

Congenital ante flexion of the uterus. POTHERAT. Bull. méd., Par., 1913, xxvii, No. 35.

End results of my operation for retroflexion of the uterus. EWALD. Wien. med. Wchnschr., 1913, lxiii, No. 21.

The disadvantages of ventrofixation. ALLMANN. Zentralbl. f. Gynäk., 1913, xxxvii, 649.

Myohysteropexy. JACOBOWICI. Revista de chir., 1913, i, No. 1.

A perforation of the fundus uteri. KÜSTNER. Deutsche Gesellsch. f. Gynäk., Halle, 1913, May. [318]

Perforation of the uterus resulting from criminal abortion. ASCH. Monatschr. f. Geburtsh. u. Gynäk., Berl., 1913, xxxvii, 701.

A rare case of uterine traumatism. MALY. Zentralbl. f. Gynäk., 1913, xxxvii, No. 2.

Removal of danger of peritonitis by the operative treatment of ruptured uterus. SIGWART. Deutsche Gesellsch. f. Gynäk., Halle, 1913, May. [318]

Abdominal hysterectomy by anterior ablation in cases of bilateral pyosalpinx. H. BARNSBY. Tours méd., 1913, ix, 45.

Adnexal and Periuterine Conditions

Ovarian secretion; a review. A. L. MCILROY. J. Obst. & Gynec. Brit. Emp., 1913, xxiii, 265.

Conservation of ovarian tissue and its power of compensation. D. F. LEE. Indianapolis M. J., 1913, xvi, 180.

Study of the ovum of the guinea-pig in the first stages of embryogenesis. H. LAMS. Arch. de biol., Gand, 1913, xxviii, 229.

Development of the ovum in Podura aquatica. L. DE WINTER. Arch. de biol., Gand, 1913, xxviii, 197.

The ovarian function in Basedow's disease. O. FRANKL. Deutsche Gesellsch. f. Gynäk., Halle, 1913. [318]

Ovarian dyspepsia. H. G. WEBB. Practitioner, Lond., 1913, xc, 897.

Anatomical study of four ovarian grafts in woman. TUFFIER and VIGNES. Bull. et mém. Soc. anat. de Par., 1913, lxxxviii, 148.

The autoplasmic ovarian graft and its clinical value. B. WHITEHOUSE. Clin. J., 1913, xlii, 107. [319]

The conditions of sterilization of the ovary by X-ray. REGAUD and LACASSAQUE. Compt. rend. hebdom. de la Soc. de Biologie, 1913, lxxiv, 783. [319]

The clinical significance of points of follicular ruptures in the ovary. COHN. Arch. f. Gynäk., 1913, xcix, No. 3.

A case of post-partum pyovarium. OHMAN. Finsk. läkar-sällsk. handl., Helsingfors, 1913, lv, April.

A note on typhoid infection of ovarian cysts. J. BLAND-SUTTON. Universal M. Rec., 1913, iii, 385. [319]

Ovarian cyst with twisted pedicle. O. B. WIGHT. Northwest Med., 1913, v, 140. [319]

Dermoid cyst of the right ovary containing teeth, demonstrated by radiography and simulating a stone in the right ureter. GOSSET. Bull. et mém. Soc. chir. de Par., 1913, xxxix, 707.

Tubo-ovarian cysts. E. TÉDENAT and A. RIVES. Province méd., Par., 1913, xxvi, 203.

The disadvantages of conservative operations for ovarian cyst. SILHOL. Arch. mens. d'obst. et de gynéc., Par., 1913, ii, No. 4.

A case of malignant multilocular cyst of the ovary in a young girl. D. M. COWIE. Physician & Surg., 1913, xxxv, 200. [320]

Primary cancer of the ovary. MASSABUAU and ÉTIENNE. Rev. de gynéc. et de chir. abdom., Par., 1913, xx, No. 3.

Case of adeno-carcinoma of the right ovary, developing later in the left; operations; recovery. W. P. CARR. Va. M. Semi-Month., 1913, xviii, 91.

Pathology and therapy of inflammatory diseases of the uterine adnexa. FALGOWSKI. Gaz. lék., Warszawa, 1913, xxxiii, No. 18 and Gynäk. Rundschau, 1913, vii, No. 0.

Primary malignant neoplasm of the fallopian tube. F. B. GURD. Canad. M. Ass. J., 1913, iii, 389. [320]

Hæmatocele of the broad ligament caused by rupture of a tubal pregnancy. H. PAUCOT. Rev. prat. d'obst. et de pædiat., Par., 1913, xxvi, 76.

A case of extra-peritoneal adenomyoma and two cases of intra-peritoneal myomata of the round ligament, with

notes on the origin of epithelial inclusions. WEISHAUP. Arch. f. Gynäk., Berl., 1913, xcix, No. 3.

An operation for ventrosuspension by the round ligaments. H. NEUHOF. J. Am. M. Ass., 1913, lx, 1701.

A clinical lecture on pelvic cellulitis. J. B. HELLIER. Clin. J., 1913, xlii, 81.

External Genitalia

Glass ball in vagina for fifteen years. G. S. VON WEDELSTAEDT. South. Cal. Practitioner, 1913, xxviii, 172.

Vaginismus. FÖNNUS. Nord. med. Ark., Stockholm, 1913, xlv, May.

Hæmatoma of the vagina and of the external genitalia. OUNGER-BRIANZEFF. Russk. Vrach, St. Petersburg., 1913, xii, No. 14.

Thrombus and vulvo-vaginal hæmatoma. CAUWENBERGHE. Bull. Soc. belge de gynéc. et d'obst., 1913, xxxiii, 167. [320]

The origin of the micro-organisms in emphysematous colpitis. ALCHEL. Zentralbl. f. Gynäk., 1913, xxxvii, No. 19.

Vaginal carcinoma. J. FEUCHTWANGER. München. med. Wchnschr., 1913, lx, 1062.

Two cases of primary epithelioma of the vagina. TOURNEUX and GINESTY. Toulouse méd., 1913, xv, No. 8.

The utilization of the small intestine in the creation of a missing vagina. SCHWARTZ and RÉNON. Bull. et mém. Soc. de chir. de Par., 1913, xxxix, 403.

Creation of a new vagina with report of a case of transplantation of the small intestine into the vagina. BROUHA. Bull. Acad. r. Med. de Belgique, 1913, xxvi, 152. [320]

Vesico-vaginal fistula cured by transplantation of fascia lata. SCHMID. Ztschr. f. gynäk. Urol., Leipzig, 1913, iv, 33. [320]

Contribution to the study of primary carcinoma of the vulva. SAVARÈ. Ann. di ostet. e ginec., 1913, xxxv, 238. [321]

Incomplete ano-vulvar atresia (atresia anivaginalis). D. C. SELVAS Y BOTÓG. Med. de los niños, 1913, xiv, 90.

Basedow and genital glands. GRAFF and NOVAK. Deutsche Gesellsch. f. Gynäk., Halle, 1913. [321]

A contribution to the chemistry of vaginal secretions. E. GRÄFENBERG. Deutsche Gesellsch. f. Gynäk., Halle, 1913. [321]

The causes and treatment of vaginal discharges. JOLY. Ann. de la policlin. centr. de Brux., 1913, xiii, No. 3.

The treatment of leucorrhœa in a woman. KATZ. Berl. klin. Wchnschr., 1913, l, No. 17.

Gonorrhœa in the female. F. R. FURSEY. Med. Council, 1913, xviii, 169.

The treatment of gonorrhœal infections with tanargentan suppositories. R. POLLAND. Deutsche med. Wchnschr., 1913, xxxix, 656. [322]

Contribution to melano-sarcoma of the clitoris. E. VOGT. Arch. f. Gynäk., 1913, xcix, 364. [322]

Cysts in the region of the clitoris. LEFEVRE and LOUBAT. Paris méd., 1913, No. 22.

Miscellaneous

Spontaneous gangrene of the genital organs in man and in woman. SPILLMAN, THIRY and BENECH. Paris méd., 1913, ii, 319. [322]

The thyrogenous etiology of hæmorrhagic metropathies,

with remarks on the theory of eclampsia and habitual miscarriages. SEHRT. München. med. Wchnschr., 1913, lx, No. 18.

Cases illustrating certain urinary conditions in women associated with frequent or painful micturition. D. NEWMAN. Glasgow M. J., 1913, lxxix, 342.

Calculi deposited about a ligature in the female bladder. HIRSCHBERG. Ztschr. f. gynäk. Urol., 1913, iv, No. 3.

Endoscopic exploration of the bladder and the ureters in uterine cancer. LENORMANT. Presse méd., Par., 1913, xxi, No. 43.

Menstrual molimina. C. CHISHOLM. J. Obst. & Gynec. Brit. Emp., 1913, xxiii, 288. [322]

The relation of acute infectious diseases to the female genitalia. STOLZ. Klin.-therap. Wchnschr., Berl., 1913, xx, No. 18.

Clinical manifestations of genital tuberculosis in women. W. O. HENRY. Med. Herald, 1913, xxxii, 175. [323]

Management of genital tuberculosis in women. P. FINDLAY. Med. Herald, 1913, xxxii, 181. [323]

The influence of the climacteric on cancer. THEILHABER. Deutsche Gesellsch. f. Gynäk., Halle, 1913, May. [323]

Multiple primary cancer of the female genital organs. HAUSER. Arch. f. Gynäk., 1913, xcix, 339. [324]

Specific treatment in pelvic infections. J. FARBACH. Lancet-Clin., 1913, cix, 511.

The bacteriological control of asepsis in gynecological laparotomies. W. SIGWART. Arch. f. Gynäk., Berl., 1913, xcix, 284.

Psychopathies of genital origin. R. SCHOCKAERT. Bull. Soc. belge de gynéc. et d'obst., Brux., 1913, xxiii, 263.

The employment of phobol in gynecological and obstetrical practice. J. S. KALABIN. Pract. Vrach, St. Petersburg., 1913, xii, 243.

A case of acromegaly following castration in an adult woman. K. GOLDSTEIN. München. med. Wchnschr., 1913, lx, 757. [324]

Methods of physical treatment in gynecology. FRANZ. Ztschr. f. ärzte, Fortbild, 1913, x, 137. [324]

Synthetic Hydrastin-Bayer, a substitute for fluid extract hydrastis canadensis. WALTHER, München. med. Wchnschr., 1913, lx, 694. [325]

X-ray treatment in gynecology. KLOTZ. Deutsche Gesellsch. f. Gynäk., Halle, 1913. [325]

Röntgenotherapy in gynecology. KREUZFUCHS. Deutsche med. Wchnschr., 1913, xxxix, No. 19.

Technique of X-ray treatment in gynecology. FRANKL. Gynäk. Rundschau, 1913, vii, 247. [325]

Röntgen rays and mesothorium in gynecological therapeutics, especially also in uterine cancer. DÖDERLEIN. Monatschr. f. Geburtsh. u. Gynäk., Berl., 1913, xxxvii, No. 5.

Statistical study of the published cases of gynecological affections treated by Röntgen rays up to the first of January, 1913. MOHR. Fortschr. a. d. Geb. d. Röntgenstr., 1913, xx, No. 2.

Gynecological deep Röntgen-ray therapy. ALBERS-SCHÖNBERG and GAUSZ. Zentralbl. f. Gynäk., 1913, xxxvii, 604.

A new uterine curette. JAMBE. Rev. méd. de la suisse Rom., Genève, 1913, xxxiii, No. 5.

OBSTETRICS

Pregnancy and Its Complications

A case of full term ectopic gestation with a dead foetus retained in the abdominal cavity for eight months. R. PETERSON. *Physician & Surg.*, 1913, xxxv, 198. [326]

A case of pregnancy five years after a piccoli operation for puerperal inversion of the uterus. NEUGEBAUER. *Zentralbl. f. Gynäk.*, 1913, xxxvii, 529. [326]

Clinical data on extra-uterine pregnancy. CHOMIAKOVA-BOUCLOVA. *J. akush. i jensk. bolez.*, St. Petersburg, 1913, xxviii, April.

Diagnosis and treatment of extra-uterine pregnancy; also communications with regard to an uninterrupted series of over one hundred operative cures. MUHSAM. *Therap. d. Gegenw.*, Berl., 1913, liv, No. 3.

A concomitant extra-uterine and intra-uterine pregnancy. JARCA. *Revista de chir.*, 1913, i, No. 1.

A case of full term extra-uterine pregnancy with living child. N. G. KRASNOPOLSKY. *Russ. Monatschr. f. Geburtsh. u. Gynäk.*, 1913, xxviii, 225. [326]

The treatment of extra-uterine pregnancy. FALK. *Arch. f. Gynäk.*, Berl., 1913, xcix, No. 3.

Coincidence of tubal and uterine pregnancy. CLAVERIS. *Normandie méd.*, Rouen, 1913, xxix, No. 9.

Full term pregnancy in an accessory tube of a bicorant uterus. HOLLÄNDER. *Arch. mens. d'obst. et de gynec.*, 1913, ii, 393. [326]

Interstitial pregnancy. SIEFART. *Zentralbl. f. Gynäk.*, 1913, xxxvii, 375. [327]

Young ovarian pregnancies. PAUCOT and DEBEYRE. *Echo méd. du nord, Lille*, 1913, xvii, No. 20.

Total ablation of the uterus associated with multiple fibromata during pregnancy. TERECHENKOFF. *J. akush. i jensk. bolez.*, St. Petersburg, 1913, xxviii, April.

Carcinoma of the uterus in pregnancy. FLOHIL. *Nederl. Maanschr. v. Verlosk. en Vrouwenz. en Kindergeneesk.*, Amst., 1913, ii, 18.

Pregnant uterus of three months associated with a large portiocarcinoma causing a foul discharge. WEINBRENNER. *München. med. Wchnschr.*, 1913, lx, 1232.

Pituglandol in the treatment of placenta prævia. P. GALL. *Zentralbl. f. Gynäk.*, 1913, xxxvii, 334. [327]

The toxæmias of pregnancy. W. G. DARLING. *Wis. M. J.*, 1913, xi, 375.

Pregnancy-serum; therapy of pregnancy toxicoses. W. RÜBSAMEN. *Deutsche med. Wchnschr.*, 1913, xxxix, 931.

Symptoms and pathology of eclampsia. J. M. BUCH. *Hosp. Bull. Univ. Md.*, 1913, ix, 41.

Eclampsia and its treatment. A. Y. LINVILLE. *South-ern M. J.*, 1913, vi, 331.

Carbohydrate metabolism in pregnancy and in eclampsia; a few words concerning the insufficiency of the liver. W. C. BENTHIN. *Monatschr. f. Geburtsh. u. Gynäk.*, 1913, xxxvii, 305. [327]

Researches on puerperal eclampsia. CHIRIÉ. *Epilepsia*, 1913, iv, 194. [327]

The toxicity of urine during the puerperium and in eclampsia. ZINSSER. *Zentralbl. f. Gynäk.*, 1913, xxxvii, 481. [327]

The state of viscosity of the blood in eclampsia as well as in other affections and lesions of the female organism. ENGELMANN and ELPERS. *Gynäk. Rundschau*, Berl., 1913, vii, No. 9.

Cæsarean section. J. M. WILSON. *Southern M. J.*, 1913, vi, 334.

The classical Cæsarean operation. KOUTACOFF. *Vrach. Gaz.*, St. Petersburg, 1913, xx, No. 17.

The technique of the Cæsarean section. J. VEIT. *Zentralbl. f. Gynäk.*, 1913, xxxvii, 713.

Cæsarean section because of vaginal stenosis following a previous operation for vesical fistula. BECKMANN. *Ztschr. f. gynäk. Urol.*, Leipzig, 1913, iv, No. 3.

Cæsarean section, with especial reference to the rarer indications for the operation. W. H. MAXWELL. *Brit. M. J.*, 1913, i, 1105.

The Cæsarean operation upon the dead and upon the dying. KITNERA. *J. akush. i jensk. bolez.*, St. Petersburg, 1913, xxviii, April.

The results obtained with the Cæsarean section in Russia during the last twenty-five years. POBEDINSKY. *Zentralbl. d. Gynäk.*, 1913, xxxvii, No. 21.

The treatment of abortion. E. B. HOWELL. *Iowa M. J.*, 1913, xix, 566.

Consideration of the treatment of abortion. R. F. ZAPPI. *Clin. Ostetr.*, 1913, xv, 130. [328]

The treatment of septic abortion. AUBERT. *Rev. suisse de méd.*, 1913, xiii, No. 15.

End results of the conservative treatment of streptococcus abortion. M. TRAUGOTT. *Deutsche Gesellsch. f. Gynäk.*, Halle, 1913. [328]

Pregnancy, delivery and puerperium in extensive hemilateral telangiectasis with formation of varicose veins associated with lymphangiectatic elephantiasis. DREWS. *Berl. klin. Wchnschr.*, 1913, i, No. 17.

Pregnancy during leucæmia and its influence on the composition of the blood. G. J. MELNIKOFF and G. T. ZOMAKION. *Russk. Vrach*, 1913, xxii, 294. [328]

A case of severe endometritis in pregnancy. ALBERT. *Deutsche Gesellsch. f. Gynäk.*, Halle, 1913. [329]

The treatment of pregnancy pyelitis. BRONGERSMA. *Nederl. Tijdschr. v. Geneesk.*, Amst., 1913, i, 529. [329]

Pyelonephritis of pregnancy. LE FUR. *Paris chir.*, 1913, v, No. 2.

Cholecystitis and cholelithiasis associated with pregnancy. R. M. GREEN. *Boston M. & S. J.*, 1913, clxviii, 679. [329]

Addison's disease and pregnancy. E. VOGT. *Deutsche Gesellsch. f. Gynäk.*, Halle, 1913, May. [329]

Pregnancy, labor and puerperium in a case of extensive unilateral telangiectases and varicose formation with lymphatic elephantiasis. DREWS. *Berl. klin. Wchnschr.*, 1913, i, 779. [329]

Thyroid and pregnancy. E. MOSBACHER. *Deutsche Gesellsch. f. Gynäk.*, Halle, 1913, May. [330]

Thyroid and pregnancy. GRAFF. *Deutsche Gesellsch. f. Gynäk.*, Halle, 1913, May. [330]

Changes in the pineal glands in pregnancy. ASCHNER. *Deutsche Gesellsch. Gynäk.*, Halle, 1913, May. [330]

Disturbances of metabolism in pregnancy, labor and puerperium. SEITZ. *Deutsche Gesellsch. f. Gynäk.*, Halle, 1913, May. [330]

Heart lesions in pregnancy. KREISS. *Deutsche Gesellsch. f. Gynäk.*, Halle, 1913, May. [332]

Albuminuria in pregnancy. ASCHNER. *Deutsche Gesellsch. f. Gynäk.*, Halle, 1913, May. [333]

Researches concerning the after life of pregnancies complicated by heart and kidney lesions. K. BAISCH. *Deutsche Gesellsch. f. Gynäk.*, Halle, 1913. [333]

The interruption of pregnancy in disease of the kidneys. SCHLAYER. *Deutsche Gesellsch. f. Gynäk.*, Halle, 1913, May. [333]

Bilateral ovariectomy during pregnancy. FUCHS. *Monatschr. f. Geb. u. Gynäk.*, 1913, xxxvii, 525. [334]

The etiology of hydrorrhœa amniotica. S. DIETRICH. *Zentralbl. f. Gynäk.*, 1913, xxxvii, 645.

Retro-placental hæmorrhage. P. RUDAUX. *Clinique, Par.*, 1913, viii, 260.

Labor and Its Complications

The duties of the physician toward a woman in labor. E. A. COTRET. *Union méd. du Canada*, Montreal, 1913, xlii, 31.

Difficult labor caused by foetal ascites. G. LUKER. *Lancet*, Lond., 1913, clxxxiv, 1309.

Death of woman in labor as a result of dilatation of the œsophagus. N. RIZZACASA. *Gior. internaz. d. sc. med.*, Napoli, 1913, xxxv, 301.

How many full-term children in cephalic presentation pass the inlet spontaneously in flat pelvis and are born alive? P. ESCH. *Deutsche Gesellsch. f. Gynäk.*, Halle, 1913. [333]

Breech presentations in the Amsterdam Clinic for Women from 1902 to 1911. H. TREUB. *Nederl. Tijdschr. v. Verlosk. en gynæc.*, Haarlem, 1913, xxii, 103. [334]

Foetal abnormality complicating delivery. D. S. HANSON. *Cleveland M. J.*, 1913, xii, 323.

Difficult delivery following vaginal fixation; a case complicated by papyraceous foetus. UTHMOLLER. *Zentralbl. f. Gynäk.*, 1913, xxxvii, No. 18.

A case of rupture of the uterus during delivery; recovery. OUTROBINE. *J. akush. i jensk. bolez.*, St. Petersburg, 1913, xxviii, April.

Recurrent ruptures of the uterus during delivery. MIRONOVA. *Russk. Vrach*, St. Petersburg, 1913, xii, No. 16.

Case of rupture of vaginal fornix during labor. E. A. BJÖRKENHEIM. *Zentralbl. f. Gynäk.*, 1913, xxxvii, 269. [334]

A case of uterine rupture following the employment of pituitrin. HERTZ. *Zentralbl. f. Gynäk.*, 1913, xxxvii, No. 20.

Abruptio of placenta due to short cord. W. C. QUINCY. *Med. World*, 1913, xxxi, 199.

Utero-pelvic phlebitis in women in confinement. JEANIN. *Paris méd.*, 1913, No. 22.

The use of the obstetric forceps. W. RITTENHOUSE. *Am. J. Clin. Med.*, 1913, xx, 403.

Puerperium and Its Complications

A contribution to the etiology of late hæmorrhages in the puerperium. F. A. LOOFS. *Beitr. z. Geburtsh. u. Gynäk.*, 1913, xviii, 225. [334]

Differential diagnosis of hæmorrhages in interrupted tubal pregnancy and in early uterine abortion. FÜTH. *Med. Klin.*, 1913, ix, No. 21.

Three cases of symmetrical necrosis of the cortex of the kidneys, associated with puerperal eclampsia and suppression of urine. R. JARDINE and A. M. KENNEDY. *Lancet*, Lond., 1913, clxxxiv, 1291.

Inversion of uterus in puerperium. W. ZANGEMEISTER. *München. med. Wchnschr.*, 1913, lx, 616. [335]

An extraordinary case of extensive necrosis of the puerperal uterus. VON REDING. *Cor.-Bl. f. schweiz. Ärzte*, 1913, xliii, No. 21.

A critical review of the medical and surgical treatment of puerperal eclampsia. G. ZINKE. *Lancet-Clin.*, 1913, cix, 603. [335]

Prophylactic treatment of puerperal infection by intra-

venous injection of collargol. COHN. *Revista de chir.*, 1913, i, No. 1.

Puerperal traumatic neuritis. MESSA. *Ginecologia*, Milano, 1913, ix, No. 23.

Post-partum paralysis of the peroneal nerve. STAUDE. *Monatschr. f. Geburtsh. u. Gynäk.*, Berl., 1913, xxxvii, No. 5.

Miscellaneous

Is obstetrics surgery? S. LEIGH. *Va. M. Semi-Month.*, 1913, xviii, 81.

Obstetrics in the country. M. A. WARHURST. *J. Okla. St. M. Ass.*, 1913, v, 536.

Obstetrics among the Indians. G. W. HARVEY. *Calif. Eclectic M. J.*, 1913, vi, 99.

The pulse and arterial pressure in the new-born. P. BALARD. *Gaz. d. hôp.*, Par., 1913, lxxvi, 837.

Researches on sex determination. A. PINARD and MAGNAN. *Compt.-rend. hebd. Acad. d. sc.*, Par., 1913, clvi, 1396.

The origin of respiratory movements in the foetus. B. DEDEK. *Lek. rozhledy*, 1913, ii, 82. [336]

The influence of the X-rays on the foetal membranes. M. KAWASOYE. *Zentralbl. f. Gynäk.*, 1913, xxxvii, 488. [336]

Demonstration of a foetus with a solid embryoma of coccyx. E. AULHORN. *München. med. Wchnschr.*, 1913, lx, 667. [336]

A case of foetal retention; diagnosis by radiography. A. SCHWAAB and ALBERT-WEIL. *Bull. et mém. Soc. de radiol. méd. de Par.*, 1913, v, 109.

A case of malformation during the eighth month of pregnancy. BAISCH. *Monatschr. f. Gesellsch. u. Gynäk.*, 1913, xxxvii, 538.

The time when luetic infection occurs in the foetus and its clinical significance. TRINCHESE. *Beitr. z. Geburtsh. u. Gynäk.*, 1913, xviii, 201. [336]

A case of delayed maconium expulsion. M. SOLDIN. *Jahrb. f. Kinderheilk.*, 1913, lxvii, 453. [337]

The determination of pregnancy during the first three months made difficult on account of pathological conditions directly or reflexively involving the generative organs. A. E. SMITH. *Am. Inst. of Homœopathy*, 1913, v, 1180.

Practical application of Abderhalden's biological test of pregnancy. H. SCHWARZ. *Interst. M. J.*, 1913, xx, 393.

Experience with the Abderhalden reaction. SCHLIMPERT. *Deutsche Gesellsch. f. Gynäk.*, Halle, 1913. [337]

Researches on the utility of Abderhalden's ferment reaction in pregnancy and carcinoma. MARKUS. *Berl. klin. Wchnschr.*, 1913, l, No. 17.

Concerning Schottlander's publications on the determination of the length of pregnancy by means of histological examination of the placenta. PETERS. *Zentralbl. f. Gynäk.*, 1913, xxxvii, 373. [337]

Alterations of the blood during pregnancy. CANTONI. *Arch. f. Gynäk.*, Berl., 1913, xcix, No. 3.

Surgical treatment of hæmorrhages of pregnancy, labor, and the puerperium. BAR. *Gynäk. Rundschau*, 1913, vii, 163. [337]

Is albuminuria likely to occur in successive pregnancies? M. SLEMONS. *Am. J. Obst.*, N. Y., 1913, lxvii, 849. [338]

Significance of urinalysis in pregnancy. J. C. CUNNINGHAM. *J. Ark. M. Soc.*, 1913, ix, 286.

The relation of the affections of the urinary organs to pregnancy, delivery and puerperium. ZANGEMEISTER. *Deutsche Gesellsch. f. Gynäk.*, Halle, 1913.

The abstraction of calcium salts from the mother's blood by the foetus, the cause of the rapid progress of tubercular processes. J. G. DRENNAN. *Am. J. Obst.*, N. Y., 1913, lxvii, 893.

The position of the uterus after delivery, at term and during the sequelæ of immediate and tardy delivery. BOUFFE and SAINT-BLAISE. *Paris méd.*, 1913, No. 22.

Crédé's manipulation and uterine inversion. BIERER. *Deutsche med. Wchnschr.*, 1913, xxxix, No. 21.

Serological and clinical investigations concerning pregnancy pyelitis. I. Anti-bodies in the maternal and foetal blood in pregnancy pyelitis. W. WEIBEL. *Arch. f. Gynäk., Berl.*, 1913, xcix, 245.

A case of a hydatiform mole. WEYMEERSCH. *J. méd. d. Brux.*, 1913, xix, No. 17.

A case of ectoplacental epithelioma. BASSAL and CLERMONT. *Arch. gén. de chir., Par.*, 1913, vii, No. 4.

Action of the placental extract upon the vascular system and upon blood coagulation. G. COLLE. *Gazz. d. osp. e d. clin., Milano*, 1913, xxxiv, 394. [338]

The effect of hypophyseal extract (pituglandol). M. GUGGENHEIM. *Med. Klin.*, 1913, ix, 755.

The treatment of syphilis in pregnant women by means of salvarsan. LEREDDE. *J. de méd. de Par.*, 1913, xxxiii, 325.

Momburg's method. BOULATNIKOFF. *Kharkovsky med. J., Kharkov*, 1913, xv, No. 2.

GENITO-URINARY SURGERY

Kidney and Ureter

Morphological study of the arteries of the suprarenal capsules in man. G. GÉRARD. *J. de l'anat. et de physiol., Par.*, 1913, xlix, 269.

Suprarenal glands and toxic infections. A. MARIE. *Ztschr. f. Immunitätsforsch. u. exp. Therap.*, 1913, xvii, 420.

The relation between chromaffin substance and adrenalin in the suprarenal capsules. W. NOWICKI. *Przegl. chir. i ginek.*, 1913, vii, 169. [339]

The origin of the hydatids of Morgagni. MACCABRUNI. *Ann. di ostet. e ginec., Milano*, 1913, xxxv, No. 4.

The physiology of kidney innervation. LOBENHOFFER. *Deutscher chir. Kong.*, 1913. [339]

The sympathetic relationship of the kidneys. CATHELIN. *Bull. méd., Par.*, 1913, xxvii, No. 39.

Secretion of hæmoglobin through the kidneys. H. RIBBERT. *Zentralbl. f. allg. Path. u. path. Anat.*, Jena, 1913, xxiv, 241.

The renal origin of certain hæmoglobinuria in children. GAUJOUX. *Sud méd., Marseille*, 1913, xlv, No. 1960.

So-called essential hæmaturia. A. SCHÜPBACH. *Ztschr. f. urol. Chir.*, 1913, i, 270.

The arteries of the healthy and of the diseased kidney in the X-ray picture. HAUCH. *Fortschr. a. d. Geb. d. Röntgenstr., Hamb.*, 1913, xx, No. 2.

The weight of the kidney in the various surgical affections of this organ. CATHELIN. *Paris chir.*, 1913, v, No. 2.

Radiodiagnosis of pseudo-calculi of the kidney. M. PONZIO. *Arch. d'élect. méd., Bordeaux*, 1913, xxi, 258.

Renal and urethral calculi. I. ABELL. *Ky. M. J.*, 1913, xi, 406. [339]

Subparietal rupture of the kidney, with report of cases. A. H. BARKLEY. *Lancet-Clin.*, 1913, cix, 475. [340]

The physical treatment of floating kidney. L. FELLMER. *Ztschr. f. Balneol., Klimatol. u. Kurort-Hyg.*, 1913, v, 711.

Experimental researches on torsion of the kidney. G. RAZZABONI. *Pathologica*, 1913, v, 230.

The clinical significance of malformations of the kidney, the renal pelvis, and the ureters. C. ADRIAN and A. VON LICHTENBERG. *Ztschr. f. urol. Chir., Leipz.*, 1913, i, 139.

Dilation and infection of the renal pelvis. VOELCKER. *Ztschr. f. urol. Chir., Leipz.*, 1913, i, 112. [340]

Colon bacillus infection of the kidney. W. AYRES. *Med. Rec.*, 1913, lxxxii, 968.

Diagnosis and treatment of bilateral renal tuberculosis. C. PERRIER. *Rev. med. de la Suisse Roma*, 1913, xxxiii, 313.

The medical treatment of renal tuberculosis. ORAISON. *J. de méd. de Bordeaux*, 1913, xlii, No. 21.

Tuberculin in the treatment of urinary tuberculosis. BARTRINA. *Ann. d. Acad. y Lab. de cienc. med. de Catalunya, Barcel.*, 1913, vii, No. 4.

A case of post-operative serous perinephritis. BAUER-EISEN. *Ztschr. f. gynäk. Urol.*, 1913, iv, No. 3.

Symptoms of intestinal occlusion in nephritic colic. GUÉNU. *Bull. méd.*, 1913, xxvii, 207. [341]

A case of right intermittent hydronephrosis provoked by two accessory renal arteries; operation with removal of these vessels; recovery. ALEMAN. *Nord. med. Ark., Stockholm*, 1913, xlv, May.

Primary tumors of the renal pelvis. MOCK. *J. d'urol., Par.*, 1913, iii, No. 5.

Complex tumor of the kidney, associated with nodules of hypernephroma. ROMANO. *Folia urol., Leipz.*, 1913, vii, No. 8.

Epithelioma of the kidney of the foetal type. MÜLLER and SAVV. *Loire méd.*, 1913, xxxii, No. 5.

The structure and histogenesis of congenital kidney neoplasms. DIENST. *Ztschr. f. gynäk., Urol.*, 1913, iv, 45. [341]

Perirenal hæmatoma. SPEESE. *Surg., Gynec. & Obst.*, 1913, xvi, 570. [342]

Voluminous cysts of the kidney. Cystostomy in addition to nephrectomy as a treatment for very advanced reno-vesical tuberculosis. PASQUEREAU. *Gaz. méd. de Nantes*, 1913, xxxi, No. 18.

Large solitary cysts of the kidney. H. MENDELSON. *Ztschr. f. urol. Chir.*, 1913, i, 295.

Hæmorrhagic cyst of the kidney; serous cyst of the kidney. GUILIANI. *J. d'urol., Par.*, 1913, iii, No. 5.

Preliminary report upon the use of indigo-carmin intravenously as a test of renal function. H. D. FURNISS. *Surg., Gynec. & Obst.*, 1913, xvi, 567. [342]

The value of pyelography in the diagnosis of surgical diseases of the kidney. F. E. KEENE. *Penn. M. J.*, 1913, xvi, 616.

Acute septic infection of the kidney and its surgical treatment. E. JOSEPH. *Urol. & Cutan. Rev.*, 1913, xvii, 189. [342]

Experiences with the transplantation of kidneys. MANTILLI. *Gazz. d. osp. e d. clin., Milano*, 1913, xxxiv, No. 54.

Decapsulation of the kidney. WARITCHEFF. *Chir. arch. Veliaminova, St. Petersburg*, 1913, xxix, No. 2.

Renal function after decapsulation of the kidney. LA-FEYRE. *J. de Physiol. et de Pathol. gen.*, 1913, xv, 241. [342]

Anatomical lesions of the kidney following artificial occlusion of the ureter. KAWASOYE. *Ztschr. f. gynäk. Urol.*, 1913, iv, No. 3.

Contribution to the study of calculi of the intraparietal portion of the ureter. PASCUAL. *J. d'Urol.*, 1913, iii, 447. [343]

Calculus of the right pelvic ureter. NOGIER. *Lyon méd.*, 1913, cxx, No. 20.

An instance of large ureteral calculus and some other cases of calculi. G. WHERRY. *Brit. M. J.*, 1913, i, 1043.

Incarcerated ureteral calculi. E. BOROSS. *Beitr. z. klin. Chir.*, 1913, lxxxiv, 94.

Impacted ureteral calculi released by fulguration. H. D. FURNISS. *J. Am. M. Ass.*, 1913, lx, 1534. [343]

Passage of ureteral stones after intra-ureteral manipulations. J. L. RANSOHOFF. *Lancet-Clin.*, 1913, cix, 537.

Bilateral ureterolithotomy in calculus anuria. A. LÄWEN. *Beitr. z. klin. Chir.*, 1913, lxxxiv, 411.

Hæmaturia. V. C. PEDERSEN. *N. Y. M. J.*, 1913, xcvi, 905.

Infections of the upper urinary tract in infancy and childhood. R. M. GREEN. *Boston M. & S. J.*, 1913, clxviii, 645. [344]

Case of ureteral abscess. W. A. JACK. *Wash. M. Ann.*, 1913, xii, 179.

Congenital fistula of the ureter. UTEAU and BASSAL. *J. d'Urol., Par.*, 1913, iii, No. 5.

Congenital pocket of the ureter showing tardy development. THÉVENOT. *Lyon chir.*, 1913, ix, No. 5.

A case of anomalous position of the ureteral orifices. UTEAU and SAINT-MARTIN. *Toulouse méd.*, 1913, xv, No. 8.

Extravesical orifice of the ureter in a woman. HARTMANN. *Hosp.-Tid., Kjøbenh.*, 1913, lvi, No. 22.

Accessory ureters. A. PAWLOFF. *Deutsche Ztschr. f. Chir.*, 1913, cxxi, 425. [344]

Stenoses of the ureter; their relation to the genital function in man. DE MEO. *Folia urol., Leipz.*, 1913, vii, No. 9.

The effect of thyosinnamin in stenosis of the ureter. LÉVY-WEISSMANN. *J. d'Urol., Par.*, 1913, iii, No. 5.

Sounding of the ureters after Pawlik's method. J. PETRIVALSKY. *Čas. lék. Česk.*, 1913, lii, 393.

Preparing an intraperitoneal course for the urinary ducts. BOLTJES. *Beitr. z. klin. Chir.*, 1913, lxxxiv, No. 2.

Implantation of the ureters into the large intestine. LEGUEU. *Clinique, Par.*, 1913, viii, No. 20.

The local treatment of retention of urine and pus by means of ureteral catheterization. ZUCKERKANDL. *Wien. med. Wchnschr.*, 1913, lxiii, No. 22.

Bladder, Urethra, and Penis

The permeability and absorbant power of the bladder. NICLOUX and NOWICKA. *J. de physiol. et de path. gén.*, 1913, xv, 296.

Some reflections suggested by a bladder case. F. W. LARGRIDGE. *Clin. J.*, 1913, xlii, 75.

Vesical herniæ. M. CHUDOVSKY. *Beitr. z. klin. Chir.*, 1913, lxxxiv, 102.

An enormous calculus of the bladder. LOUMEAU and DELAYE. *Gaz. hebdomadaire de médecine et de chirurgie*, 1913, xxxiv, No. 19.

Diabetes and vesical calculus. GOLDBERG. *Med. Klin.*, 1913, ix, No. 17.

An extraordinary calculus formed about a foreign body. G. W. MALY. *Ztschr. f. gynäk. Urol.*, Leipzig, 1913, iv, 89.

Surgery of stone of the bladder, prostate and ureters. STEILNER. *Folia urol.*, Leipzig, 1913, vii, No. 8.

Congenital diverticulum of the bladder with a contractile orifice. BUERGER. *J. d'Urol., Par.*, 1913, iii, No. 5.

Cystoscopic pictures of bilharzia of the bladder. JOSEF. *Deutsche Ges. f. Gynäk.*, Halle, 1913.

Syphilis of the bladder. LEVY-BING and DUROEUX. *Ann. d. mal. vener.*, Par., 1913, viii, 241.

Syphilitic affections of the bladder. R. PICKER. *Orvosi hetil.*, Budapest, 1913, lvii, 136.

Gonorrhœal cystitis. R. CASTORINA. *Gazz. internaz. di med. chir.*, ig., Napoli, 1913, No. 13, 299.

Simple ulcer of the bladder. BUERGER. *Folia urol.*, Leipzig, 1913, vii, No. 9.

Simple ulcers of the bladder. LEGUEU. *Progrès méd.*, Par., 1913, xli, No. 19.

Therapeutic fistulization of the bladder. LOUMEAU. *J. d. med. d. Bordeaux*, 1913, xliii, No. 7. [344]

Five cases of bladder growth. H. T. MURSELL. *Transvaal M. J.*, 1913, vii, 246.

Removal of a carcinomatous urinary bladder and transplantation of both ureters. SAMBORSKY. *Russk. Vrach.*, St. Petersburg, 1913, xii, 568.

On the question of the so-called implantation-relapses after removal of papillomata of the urinary bladder. A. SMIRNOFF. *Arb. a. d. chir. Klin. d. Prof. Fedoroff in St. Petersburg*, 1913, vii, 33.

Some cases of retarded vesical cicatrization after suprapubic prostatectomy. THÉVENOT and LACASSAGNE. *J. d'Urol., Par.*, 1913, iii, No. 5.

Removal of a mass of chewing gum from the bladder. J. O. RUSH. *Am. J. Urol.*, 1913, ix, 236.

The value of intravesical operations. KIELLEUTHNER. *München. med. Wchnschr.*, 1913, lx, 969.

Colpocystotomy. MARCHETTI. *Riforma méd.*, 1913, xxix, No. 21.

Further remarks on hypogastric lithotomy of the empty bladder. LASTARIA. *Presse méd.*, Par., 1913, xxi, No. 44.

Some indications for suprapubic cystotomy. L. GODARD. *Am. J. Urol.*, 1913, ix, 223.

The treatment of post-operative retention of urine.

RIBACK. *Novoié v med.*, St. Petersburg, 1913, vii, No. 5.

Stricture of the urethra. A. W. NELSON. *Eclect. M. J.*, 1913, lxixiii, 238.

The effects of posterior urethral inflammation centering in a colliculitis. P. ORLOWSKI. *Urol. & Cutan. Rev.*, 1913, xvii, 254.

Gonorrhœal urethritis anterior; its treatment, with special reference to abortive measures. A. L. SACHS. *Practitioner*, Lond., 1913, xc, 841.

Diagnosis and treatment of gonorrhœal affections in general practice. P. MULZER. *Springer*: Berlin, 1913.

Communications on gonorrhœa. BRANDWEINER and HOCH. *Wien. klin. Wchnschr.*, 1913, xxvi, 882.

A new treatment of acute gonorrhœa. O. L. MULOT. *Merck's Arch.*, 1913, xv, 146.

Para-urethra. J. L. HERMAN. *N. Y. M. J.*, 1913, xcvi, 919.

Some plastic operations on the penis and urethra. H. A. FOWLER. *Am. J. Urol.*, 1913, ix, 229.

Technique of external genitoplasty in the male. BONAMY and DARTIGUES. *Presse méd.*, 1913, xxi, 93. [345]

Meatotomy; a simple method. S. H. LIKES and H. SCHOENRICH. *J. Am. M. Ass.*, 1913, lx, 1359.

An instrument for radical removal of phimoses. HANS SPITZY. *München. med. Wchnschr.*, 1913, lx, 975.

Genital Organs

The pathology of ectopy of the testicles. UFFREDUZZI. Arch. f. klin. Chir., 1913, ci, No. 1.

Torsion of the testicle. SOCHSTCHIN. Chirurgia, 1913, xxxiii, 52. [346]

Tumors of the testicles and the rôle of trauma as a cause. MIYATA. Arch. f. klin. Chir., 1913, ci, No. 2.

A case of chorion-epithelioma of retained testis with multiple metastatic growths with notes on the etiology and pathology of chorion-epithelioma. T. S. TIRUMURTI. Practitioner, Lond., 1913, xc, 814.

Orchitis of the new-born and infantilism. PAYAN and MATTEI. Marseille méd., 1913, l, No. 10.

Acute rheumatic orchitis; report of a case associated with erythema nodosum and acute torticulitis in a child aged two and one half years. M. H. BASS. J. Am. M. Ass., 1913, lx, 1608.

Affection of the epididymis, claimed as a secondary symptom of an accident. WAGNER. Med. Klin., 1913, ix, No. 20.

A suggestion for the improvement of the technique of illumination of hydroceles. P. A. GLUSCHKOW. Voïenno-med. J., St. Petersburg, 1913, ccxxxvi, 212.

The employment of autoscerotherapy in hydrocele. ZDANOWICZ. Ztschr. f. Urol., Berl., 1913, vii, No. 5.

Operative treatment of varicela. GOMOIU. Revista de chir., 1913, i, No. 1.

Vasostomy-radiography of the seminal ducts. W. T. BELFIELD. Surg., Gynec. & Obst., 1913, xvi, 568. [346]

The prostate gland and the origin of the corpora prostatica and of prostatitis hypertrophicans. G. FERULANO. Gior. internaz. d. sc. med., Napoli, 1913, xxxv, 337.

Carcinoma of the prostate. A. L. WOLBARST. Internat. J. Surg., 1913, xxvi, 164.

Carcinoma of the prostate. GEBELE. Zentralbl. f. d. Grenzgeb. d. Med. u. Chir., 1913, xvi, No. 5.

Hypertrophy of the prostate. J. M. CLEASON. N. Y. M. J., 1913, xcvi, 1019. [347]

The treatment of prostatic hypertrophy. J. R. CAULK. Tex. St. J. Med., 1913, ix, 21.

A year of surgery of the prostate. WILMS. Med. Klin., 1913, ix, 619.

Prostatectomy in the aged, with a report of two successful cases ninety years of age. H. A. MOORE. J. Indiana St. M. Ass., 1913, vi, 206.

The physical and intellectual energies after prostatectomy. LEGUEU. Bull. méd., Par., 1913, xxvii, 387.

Two cases of ulcerative granuloma of the genital organs cured by means of neosalvarsan. SABELLA. Policlin., Roma, 1913, xx, No. 5.

Total evulsion of the skin of the male genital organs. BELFRAGE. Nord. med. Ark., Stockholm, 1913, xlv, May.

Miscellaneous

Radiographic examination of the urinary tract. F. LEGUEU, P. PAPIN and G. MAINGOT. Gittler: Paris, 1913. [347]

Experimental investigations on bacterium coli infection of the urinary organs. O. HESS. Mitt. a. d. Grenzgeb. d. med. u. Chir., 1913, xxvi, 135.

The solubility of the principal stone-forming elements in the urine. LICHTWITZ. Ztschr. f. exp. Path. u. Therap., 1913, xiii, No. 2.

Tuberculin in the treatment of genito-urinary tuberculosis. C. A. COLEMAN. Ohio St. M. J., 1913, ix, 227.

Tropical or climatic buboes. A. J. J. TRIADO. Australas. M. Gaz., 1913, xxxiii, 442.

Significance of hiccup following operation on the urinary tract. MARION. J. d' urol., 1913, iii, 580. [348]

Venereal prophylaxis; why it sometimes fails. R. A. BACHMANN. J. Am. M. Ass., 1913, lx, 1610. [348]

Masturbation — injurious or harmless. W. J. ROBINSON. Am. J. Urol., 1913, ix, 238.

An unusual condition, causing impotence in the male. F. C. WALSH. Am. J. Urol., 1913, ix, 251.

Sexual impotence in the male. V. BLUM. Am. J. Urol., 1913, ix, 254.

Hermaphroditism; specimens. D. S. LAMB. Wash. M. Ann., 1913, xii, 173.

SURGERY OF THE EYE AND EAR

Eye

Angioma of the upper eyelid in a child of eighteen months, cured by bipolar electrolysis. DOLCET. Ann. d. Acad. y Lab. de cienc. med. de Catalunya, Barcel., 1913, vii, No. 4.

A case of pigmented sarcoma of the eyelid. TAMACHEFF. Russk. Vrach, St. Petersburg, 1913, xii, No. 15.

Treatment of disturbances of vision in acromegaly (operation on the canalis opticus). SCHLOFFER. Deutscher chir. Kong., 1913.

Serious injuries of the eyes and the face by so-called water-core and zodiac golf balls. OHLEMAN. Klin.-therap. Wchnschr., 1913, xx, No. 20.

Eye unconsciously injured. S. MITCHELL. Ophth. Rec., 1913, xxii, 245.

The eyes as a nidus of general infection. J. D. DODGE. Elect. M. J., 1913, lxxiii, 241.

The relation of accessory cavity disease to the eye and the orbit. E. BROWN. Ohio St. M. J., 1913, ix, 207. [349]

The influence of chronic sepsis upon eye disease. W. LANG. Lancet, Lond., 1913, clxxxiv, 1368. [349]

Streptococcic infection of both eyes. F. W. FRANKHAUSER. Penn. M. J., 1913, xvi, 646.

Tuberculosis of the eye and tuberculin. ZIEMINSKI. Med. i kron. lek., Warszawa, 1913, xlviii, No. 19.

Enucleation on account of sympathetic ophthalmia. DE LA PREDAJA. Rev. ibero-amer. de cienc. med., 1913, xxix, No. 104.

The incidence of ophthalmia neonatorum in London. N. B. HARMAN. Brit. M. J., 1913, i, 1099.

The use of vaccines in eye infections. J. G. DWYER. Arch. Ophth., 1913, xlii, 227. [349]

Restoration of the conjunctival sac. STANCULEANU and JIANU. Revista de chir., 1913, i, No. 1.

Development of membrana tectoria with reference to its structure and attachments. C. W. PRENTISS. Am. J. Anat., 1913, xiv, No. 4.

Hypopyon ulcer of the cornea and its treatment. C. M. HARRIS. Penn. M. J., 1913, xvi, 611.

A study of some forms of congenital cataract, with special reference to their clinical significance. D. T. VAIL. *Lancet-Clin.*, 1913, cix, 528. [349]

The intracapsular operation for cataract after the method of Professor Stanceanu. W. L. SIMPSON. *Ophth. Rec.*, 1913, xxii, 241. [350]

Five cases of hereditary cataract. CAMPBELL. *J. Ophth., Otol. & Laryngol.*, 1913, xix, 144. [350]

The removal of senile cataract before maturity. JENNINGS. *Med. Herald*, 1913, xxxii, 97. [350]

Another view of the extraction in the capsule cataract operation. C. B. MEDING. *Arch. Ophth.*, 1913, xlii, 241. [350]

Glaucoma. W. H. CRISP. *Colo. Med.*, 1913, x, 162.

Contribution to the pathology of hæmorrhagic glaucoma. J. STAHL. *Arch. Ophth.*, 1913, xlii, 248. [350]

The colloidal theory and its application to glaucoma. R. SATTLER. *Lancet-Clin.*, 1913, cix, 498.

Glaucomatous tension relieved by anterior sclerotomy. G. D. HALLETT. *J. Ophth., Otol. & Laryngol.*, 1913, xix, 178. [350]

Case of syphilis of the choroid and retina: Wassermann negative. J. H. WOODWARD. *Urol. & Cutan. Rev.*, 1913, xvii, 237.

A case of enlargement of the eye-ball. R. B. HIRD. *Ophth. Rev.*, 1913, xxxii, 137. [351]

Intra-ocular tumors. J. K. M. PERRINE. *J. Ophth., Otol. & Laryngol.*, 1913, xix, 180.

Blindness of left eye due to pressure of distended maxillary antrum. G. H. POOLEY and M. B. WILKINSON. *Ophth. Rev.*, 1913, xxxii, 130. [351]

A sclerocorneal trephine. B. PUSEY. *J. Am. M. Ass.*, 1913, lx, 1537.

Some impressions of the Oxford Ophthalmological Congress and the Ophthalmological section of the British Medical Association at Birmingham. MCREYNOLDS. *Tex. St. J. Med.*, 1913, vii, 332. [351]

Ear

Spontaneous gangrene of the left auricle. RICHARD. *J. de méd. de Bordeaux*, 1913, xliii, No. 20.

Ossaceous cyst of the concha. DEDEK. *Čas. lék. česk.*, Prague, 1913, lii, No. 17.

Plication of the auricular cartilage in cases of prominent ear and hæmatoma. WIEMANN. *Deutsche med. Wchnschr.*, 1913, xxxix, No. 18.

Anæsthesia by means of infiltration in oto-rhino-laryngology. JACQUES. *Rev. méd. de l'est*, 1913, xlv, No. 10.

Radical operations on the ear under local anæsthesia, its technique and after-treatment. KULENKAMPFF. *Beitr. z. klin. Chir.*, 1913, lxxxiii, 546.

Acute suppurative otitis media due to bacillus typhosus.

J. J. THOMAS and D. A. PRENDERGAST. *Cleveland M. J.*, 1913, xii, 360.

The complications of acute middle ear suppurations. G. W. MACKENZIE. *Hahneman. Month.*, 1913, xlviii, 342.

Observations on the treatment of acute suppuration of the middle ear. P. G. GOLDSMITH. *Canad. J. M. & S.*, 1913, xxxiii, 339.

Middle ear diseases in infancy and childhood. E. G. SEIBERT. *Va. M. Semi-Month.*, 1913, xviii, 62.

Inflammation of the middle ear during diseases of childhood. SCHERE and KUTVIRT. *Čas. lék. česk.*, Prague, 1913, lii, No. 14.

Chronic otitis in its relation to constitutional disease. F. G. CAWSTON. *South African M. Rec.*, 1913, xi, 158.

Lavage of the tympanic cavity. BEAL. *Ann. d. mal. de l'oreille, du larynx, du nez et du pharynx*, Par., 1913, xxxix, No. 4.

A case of mastoid abscess without otorrhœa. W. A. WELLS. *Va. M. Semi-Month.*, 1913, xviii, 56. [351]

Primary osteitis; a case of mastoiditis associated with occipital osteitis. ANTOLI. *Arch. internat. de laryngol., d'otol. et de rhinol.*, Par., 1913, xxxv, No. 2.

The operations for mastoid empyema and caries. B. ALEX RANDALL. *Therap. Gaz.*, 1913, xxxvii, 317.

Topography of the petromastoid cavity and its entrance in the adult. RAMADIER. *Ann. d. mal. de l'oreille, du larynx, du nez et du pharynx*, Par., 1913, xxxix, No. 4.

Partial chiseling open of the petromastoid bone. BONCOUR. *Ann. d. mal. de l'oreille, du larynx, du nez et du pharynx*, Par., 1913, xxxix, No. 3.

Serous and suppurative labyrinthitis — differential diagnosis. I. W. VOORHEES. *Boston M. & S. J.*, 1913, clxviii, 716. [351]

Symptomatology and pathogenesis of purulent labyrinthitis and indications for operations on the labyrinth. R. WOLFERZ. *St. Petersburg. med. Ztschr.*, 1913, xxxviii, 79.

Indications for and technique of trepanation of the labyrinth. HAUTANT. *Rev. hebdom. de laryngol. e otol. et de rhinol.*, 1913, xxxiv, No. 21. [352]

Trephining the labyrinth outside of the area of pyo-labyrinthitis. BOTEY. *Ann. d. mal. de l'oreille, du larynx, du nez et du pharynx*, Par., 1913, xxxix, No. 3.

Benign tumors of the upper respiratory passages associated with a tumor of the ear. JEDZIAK. *Przegl. lek.*, 1913, No. 18.

Two cases of endocranial complications of otic origin. BRUNETTI. *Arch. internat. de laryngol., d'otol., et de rhinol.*, Par., 1913, xxxv, No. 2.

The origin, symptomatology and operative treatment of brain abscesses caused by suppuration of the middle ear. K. UDVARHELYI. *Beitr. z. klin. Chir.*, 1913, lxxxiv, 163.

Non-operative treatment of septicæmia and of otogenous pyemia. LANG. *Čas. lék. česk.*, Prague, 1913, lii, No. 17.

SURGERY OF THE NOSE, THROAT, AND MOUTH

Primary malignant tumors of the nasal cavity and the accessory nasal sinuses. J. SAFRANEK. *Beitr. z. klin. Chir.*, 1913, lxxxiv, 126.

Tumors in the neighborhood of the ostium pharyngeum tube. LAWNER. *Monatschr. f. Ohrenheilk. u. Laryngo-Rhinol.*, 1913, xl, 262. [353]

INTERNATIONAL ABSTRACT OF SURGERY

OCTOBER, 1913

ABSTRACTS OF CURRENT LITERATURE

GENERAL SURGERY

SURGERY OF THE HEAD AND NECK

HEAD

Tuffier: Traumatic Facial Hemispasm (Hémi-spasme facial d'origine traumatique). *Bull. et mem. Soc. de chir. de Par.*, 1913, xxxix, 596.

By Journal de Chirurgie.

Tuffier presents a man thirty-seven years old, who was hit on the head and had a fracture of the bony auditory canal, followed by a suppuration in the middle ear. Slight facial paralysis with facial asymmetry came on shortly and at the end of six weeks was succeeded by symptoms of facial spasm with both gross and fibrillary contractions and some trouble with the sight.

The cause of the spasm is easily explained. The intimate connection of the facial nerve and the tympanic cavity makes it easy for the nerve to be irritated by the products of a middle ear disease and so develop functional troubles. This lesion develops from two weeks to a month after the trauma. Sometimes there is only spasm, but in others contractures between the attacks of spasms are seen. Complicating lesions of the eye or ear may be present.

This condition may last for some time, even several years, Tuffier's patient, after some weeks, seemed better and probably will recover entirely, despite the fact that there are permanent auditory and equilibratory disturbances, for there is no reaction of degeneration. The prognosis is good.

J. DUMONT.

Earl: The Limitations and Possibilities of X-Rays in Skull Diagnosis. *J.-Lancet*, 1913, xxxiii, 307.

By Surg., Gynec. & Obst.

Changes in the soft part of the brain, such as meningitis, abscess, hæmatoma or soft tumors, do not produce a sufficient change in density per se to be recognizable on the Röntgen plate. It is mainly

by their effect on the bony structures that diagnostic signs are obtained. Among the conditions producing local or general thickenings of the cranium are rickets, syphilis, acromegaly and osteitis deformans. Localized destructions may be endothelioma or metastatic tumors from the thyroid, mammary, prostate, ovary or suprarenal gland. An intracranial tumor may cause a marked local thinning of the skull by pressure atrophy.

Changes in the sella turcica and region may be due to hypophysial tumor or to other basilar growths such as tumor or cyst of neighboring structures. Primary conditions of the sphenoidal sinus may alter the form of the sella with or without affecting the bone structure. A sign of general intracranial pressure may be found in the digital impressions of the wall of the cranium-scalloped impressions separated by ridges corresponding to the outlines of convolutions. Other compression signs are the widening of the channels for the diploic veins as when the cavernous sinus is compressed the sphenoparietal sinus is seen to be greatly enlarged.

The work of localizing foreign bodies in the eye or orbit and the detection of pus and tumors in the accessory sinuses of the nose is well established and used as a routine in all the larger clinics.

HOLLIS E. POTTER.

Brown: The Diagnostic Evidence Obtained by X-Rays from the Lateral Aspect of the Skull, with Especial Reference to the Base and Its Adnexa. *Boston M. & S. J.*, 1913, clxviii, 882.

By Surg., Gynec. & Obst.

Since the contribution of Caldwell upon the value of the occipito-frontal projection of the cranium, the lateral projection has fallen more or less into disuse. All structures which are bilaterally placed are superimposed one upon the other and the picture thus obscured. But in lateral projections confirma-

tory evidence can be obtained concerning a suspected pathological condition. Frontal sinus disease, ethmoidal disease, etc., are more easily diagnosed with pictures in both planes than with the occipitofrontal alone.

In disease in the region of the sphenoid and pituitary body, the lateral view is absolutely essential to a complete understanding of the condition. There is a wide range of variations in the region of the pituitary body, all of which may or may not be called normal, and it requires a vast amount of experience to "read" accurately a lateral projection of this region.

J. H. SKILES.

Marchand: Traumatic Epilepsy (De l'épilepsie traumatique). *Clinique*, Par., 1913, viii, 210.

By Zentralbl. f. d. ges. Chir. u. i. Grenzgeb.

In this paper Marchand includes only those cases of traumatic epilepsy which followed head injuries. These constitute about 98 per cent of all cases, and occur at any age, though most of them are seen before the twentieth year. The interval between the injury and the first attack may vary greatly, but in most instances it does not exceed half a year. Convulsive attacks directly associated with the injury must be differentiated from those which do not appear till weeks or months later. The former are due to acute cerebral disturbances and usually disappear entirely with the subsidence of the acute symptoms, while the latter are the result of permanent changes which determine the convulsive attacks. The epileptic seizures happen most frequently after strong mental impressions, and the author thinks that the cerebral concussion has a great deal to do with their development. In many cases the injury is so slight that it must be looked upon as the exciting cause in an individual with a hereditary predisposition to fits. To this class belong the cases developing after trephine operations. The author denies that the surgical interference itself is the cause of the seizures, and advances the opinion that the disease for which trephining is indicated must be the cause.

HOLZWARTH.

Smirnoff: The Plastic Closure of Dural Defects (Über den plastischen Verschluss der Duradefekte des Gehirns). *Dissertation*, St. Petersburg, 1913.

By Zentralbl. f. d. ges. Chir. u. i. Grenzgeb.

This work covers the subject thoroughly. The author discards all methods employing alloplastic material. He reports the results of seventy-four experiments performed on dogs and rabbits. In the control experiments the defect was filled in by scar and glia tissue when a heteroplastic material was used. The material was slowly absorbed and a connective tissue capsule developed around it. If the cortex was not injured no adhesions formed between it and the implant. Delicate adhesions were however formed between the pia and the capsule. The author comes to the following conclusions in regard to heteroplastic methods. With brain injury present, adhesions cannot be prevented between the cortex and the

transplant. In uninjured cortex, adhesions are not observed. The least irritation of the cortex occurred when fish bladder and living peritoneum were used.

In the second part of the work the author discusses homoplastic methods. He also reports two unpublished cases in which on account of traumatic epilepsy a portion of the dura was extirpated and free fascia transplanted. He concludes that free fascial transplantation for dural defects must be given the preference above all other methods. Of special importance is the fact that it prevents cerebral prolapse. He does not consider free fat transplantation for dural defects practical and brings several arguments against this suggestion of Rehn. The cerebral pressure induced by the massive piece of fat implanted, according to the author, speaks against its practical application. Furthermore, the fixing sutures cut through the fatty tissue easily and the liquor cerebri escapes through these openings.

Smirnoff performed seven decisive experiments and comes to the following conclusions: the transplanted fat is converted into connective tissue in which islands of fat can be observed. After five weeks young connective tissue forms with new capillaries. After four months the connective tissue has become firm. In injured cortex, connective tissue from the cortex migrates into the fat. In uninjured cortex the fat lies firmly against the cortex. An extensive bibliography and twenty-one microphotographs accompany the monograph.

HESSE.

Wenglowski: The Operative Treatment of Hydrocephalus (Über die operative Behandlung des Hydrocephalus). *Chir. Arch. Weljaminsowa*, 1913, xxix, 179.

By Zentralbl. f. d. ges. Chir. u. i. Grenzgeb.

Hydrocephalus externus occurs less frequently than hydrocephalus internus. Even in the more extensive articles of Kausch, Payr, and V. Bramann, the former variety occupies only a small space. The author describes an interesting case belonging to that class. In a girl 9 months old operation revealed a large collection of fluid between the dura and the arachnoid. There were no evidences of cerebral atrophy. Free communication between the subdural space and the subcutaneous connective tissue was established to permit the fluid to drain away. To accomplish this a large piece of the dura and the skull was removed. The result was very gratifying. The fluid was rapidly absorbed by the connective tissue and the hydrocephalus disappeared. The case was observed for 5 months.

In the second part of this article the author discusses hydrocephalus internus and bases his arguments on the methods of drainage used by V. Bramann and Payr. The chief objections to ventricular drainage are the too rapid abstraction of the fluid and the variations in the pressure conditions. On this account the larger drainage tubes are to be discarded. Diverting the fluid into the general

circulation or into the abdominal cavity (Kausch) is to be avoided since by these methods the fluid is drained off too rapidly. On this account the fluid had better be led into the subdural space or into the subcutaneous tissue. A further drawback is the premature closure of the drainage opening. Wengowski made an attempt in 1906 to form a tube by utilizing the dura, and establish a communication between the subdural space and the ventricle. When employing this method great care is necessary that the dural vessels remain in communication with the flap. Formerly Boyer used the dura in the repair of a spina bifida in the lumbar region.

The author has used the method in two cases of hydrocephalus internus. The anastomosis may be made with the anterior or posterior horn of the lateral ventricle. The fluid is drained partially into the subdural space and partially into the subcutaneous tissue. In this way a wide surface is supplied for the gradual absorption of the liquid. The result in both cases operated on was very good. The late result in one case was likewise encouraging. After 1½ years the child's head was almost normal in its dimensions. The operative technique is simple, and can be carried out on rather debilitated children.

HESSE.

Archibald: Puncture of the Corpus Callosum.

Canad. M. Ass. J., 1913, iii, 451.

By Surg., Gynec. & Obst.

The problem of how best to give relief for cerebral compression from unlocalizable tumor is often a very difficult one. It is generally recognized that the subtemporal procedure of Cushing is the method of choice for the purpose of pure decompression. Sometimes, however, this method proves insufficient; in spite of a large submuscular hernia the symptoms persist. In such cases the reason may lie in the coincidence of a large hydrocephalus internus, such as is known to complicate cerebral tumor not infrequently. It was experiences of this sort which led to the puncture of the roof of the corpus callosum in an attempt to relieve the internal pressure.

The technique of the operation is as follows: On the right side, about a finger's breadth behind the coronary suture and 2 cm. from the mid-line, an opening is made with the Doyen burr, about 1.5 to 2 cm. in diameter. A slit opening is made in the dura and care is taken to avoid any large cortical vein. Then a hollow curved cannula is pushed in over the convexity of the cortex till it strikes against the falx, which membrane guides the further progress of the cannula downward, till the corpus callosum is reached. The instrument breaks bluntly through this structure with very slight force, whereupon the ventricular fluid is emptied, usually under some pressure.

The author reports four cases in which he performed puncture of the corpus callosum. Two were obstructive hydrocephalus of high grade in infants and the puncture gave only temporary relief. The

other two were cases of unlocalizable brain tumor. In one a subtemporal decompression was first done and this gave temporary relief. A second operation was performed and the corpus callosum punctured. This resulted in control of the symptoms. In the other case the puncture of the corpus callosum was done first but relief was not obtained until a subsequent subtemporal decompression was performed.

JAMES H. SKILES.

NECK

Poggiolini: Is It Always Possible to Avoid the Facial Twigs of the Cervico-Facial Branch of the VIIth Pair in Operations on the Submaxillary Fossa? (Est-il possible d'éviter toujours les rameaux faciaux de la branche cervico-faciale de la 7^e paire, dans les opérations sur la loge sous-maxillaire?) *Clin. chir.*, 1913, xxi, 1090.

By Journal de Chirurgie.

Deviations of the lower lip are frequently noted after incisions in the submaxillary fossæ and are due either to the division of the fibers of the platysma muscle or of the cervico-facial twigs of the facial nerve. They are comparatively unimportant, because, as a rule, they disappear spontaneously in time. It would, however, be desirable to avoid them altogether, if possible. According to the author, incisions must not be made in a region limited above by the posterior $\frac{2}{3}$ of the lower border of the jaw; below, by a line parallel with, and $\frac{1}{2}$ inch distant from, the precedent; behind, by the anterior border of the sterno-mastoid muscle; in front, by a line directly uniting the two first mentioned.

Six diagrams show the lines of incision the author considers safe. It may be objected that these lines remain far in front of the region where adeno-phlegmons of a very common variety have to be drained.

PIERRE FREDET.

Halpenny: The Thyroid and Parathyroid Problem.

Surg., Gynec. & Obst., 1913, xvi, 955.

By Surg., Gynec. & Obst.

The etiology of the enlargement and perverted secretion of the thyroid gland is still in doubt. It has been regarded as an infection, but could not be so demonstrated by Chambers by bacteriological methods. Chambers' work, however, points to the presence of toxins. McCarrison produced goiter by using the filtrate of a goitrous well but when the filtrate was boiled goiter could not be produced. Short believes goiter to be due to some metal which unites with iodine to form an insoluble compound.

Experiments by the author show that when the thyroid is removed the parathyroids assume the histological features of the thyroid. It is also noted that structural changes take place in the pituitary body when the thyroid is removed. Rogers' experiments indicate that there is an intimate relationship between the thyroid, pancreas and adrenals. Carlson and Woelfel demonstrated that goiter lymph when injected intravenously did not give any untoward results.

Rogers discovered thyreoglobulin and "nucleoproteid" as separate substances. Minute quantities of nucleoproteid injected subcutaneously produced acute thyroidism. The experiments up to date have not settled the question as to whether the symptoms are due to perverted or to increased thyroid secretion.

In the treatment of this condition the author recommends rest, quinine, hydrobromate, thymol and Rogers' antithyroid serum. Along surgical lines, he advises partial removal of the gland, using Crile's method of eliminating fear and nitrous oxide anæsthesia. Dunhill operates on all cases and uses local anæsthesia.

Tatum: Morphological Studies in Experimental Cretinism. *J. Exp. Med.*, 1913, xvii, 636.

By Surg., Gynec. & Obst.

Morphological observations were made on a number of rabbits which were thyroidectomized at the age of two or three weeks. At least two animals out of each litter were kept as controls. All were weighed at regular intervals. The present paper is based on a series of about twenty-five autopsies. The important observations may be summarized as follows:

Degenerative changes were noted in practically every parenchymatous organ. The most striking of these changes was serous imbibition by the most active cells of these organs. The changes noted in the glands of internal secretion corroborate the statement that removal of one gland of internal secretion results in changes in all the others. In this case, degenerative changes were marked in the hypophysis, thymus, ovary and testes, while hyperplasia was seen in the Islands of Langerhans and the medulla of the adrenal glands.

Tatum concludes that in the rabbit, athyroidism is responsible for grave degenerative changes in practically all organs and tissues of the body and that many of the symptoms of cretinism have an anatomical basis in organic cellular changes.

J. F. CHURCHILL.

Kuhn: The Frequent Occurrence of Mild Cases of Basedow's Disease and the Favorable Influence Exerted upon Them by Hygienic-Climate Factors (Über das häufige Vorkommen leichter Basedowfälle und ihre günstige Beeinflussung durch hygienisch-klimatisch Faktoren). *Med. Klin.*, 1913, ix, 834.

By Zentralbl. f. d. ges. Chir. u. i. Grenzgeb.

The author was able to observe many recruits with a mild Basedow's disease, the diagnosis being confirmed by Rehn. He ordered them to service, and in spite of the severe bodily exertion incident to service an improvement and even a disappearance of all nervous and cardiac symptoms set in. The conclusion is drawn that Basedow's disease is not always to be considered etiologically as a thyrotoxicosis, but that the primary factor frequently is a disease of the nervous system. The condition improves under a

carefree and hygienically favorable life, even though absolute rest is not adhered to. The author believes with Kurschmann that the vago-sympathetic cause of Basedow's must be accepted in many cases. The fact that cure is obtained by operation does not contradict the theory, as secondary thyroid dangers also may induce the Basedow symptoms. A table showing the findings of eleven cases examined in the Charité is appended.

SCHLENDER.

Mannaberg: An Attempt to Influence Basedow's Disease by X-Rays Applied to the Ovaries (Über Versuche, die Basedowsche Krankheit mittels Röntgenbestrahlung der Ovarien zu beeinflussen). *Wien. klin. Wchnschr.*, 1913, xxvi, 693.

By Zentralbl. f. d. ges. Gynäk. u. Geburtsh. s. d. Grenzgeb.

Based upon the theory of an interrelation existing between the thyroid gland and ovaries the author attempted to influence Basedow's disease by applying X-rays to the ovaries. The investigations were conducted on ten patients. In eight cases an increase in weight from 2.3 to 21 per cent occurred. In half of the cases the exophthalmus decreased; it disappeared entirely in one instance. The pulse rate decreased considerably in some cases, in others only slightly. Tremor was influenced favorably. The circumference of the neck and menstruation were not influenced. In three cases existing diarrhoeas disappeared after the first treatment. Two cases which improved under X-ray treatment became worse after the application of the rays to the thyroid gland, the third case remained uninfluenced.

LEMBCKE.

Schloffer: The Operative Treatment of Basedow's Disease (Über die operative Behandlung der Basedowschen Krankheit). *Prag. med. Wchnschr.*, 1913, xxxviii, 313.

By Zentralbl. f. d. ges. Chir. u. i. Grenzgeb.

The author discusses the relations between the thyroid gland and the thymus and between the *formes frustes* and the thyrotoxic goiter heart. With internal treatment only temporary improvement takes place; with operative treatment about 75 per cent of the cases result in cure. Death following the operation occurs only in advanced cachexia due to status lymphaticus. The operation usually performed is the excision of half a lobe, preceded in weak individuals by ligation of the vessels. The thyroidea inferior should be saved on account of the danger of causing injury to the parathyroids. An aggravation of the symptoms occurs immediately after the operation, but in about two days improvement sets in, the restlessness, sleeplessness and tachycardia disappearing. Gradual recession of the other phenomena and increase in weight takes place. The exophthalmos persists for a considerable time. Naturally any irreparable cardiac degeneration remains; in 70 per cent of the cases, however, general improvement occurs.

The author then states his own results. Early operation is advised. In acute cases it is best to

order a rest cure, and await the disappearance of the stormy phenomena. The author warns against X-ray treatment, iodine and thyroid preparations. At operation iodine should not be employed and

the loss of blood should be minimized. Local infiltration is the anæsthetic of choice except in highly excited patients, when a general narcosis has to be employed.

BIERNATH.

SURGERY OF THE CHEST

CHEST WALL AND BREAST

Albrecht: The Internal Secretion of the Mamma (Zur Frage der inneren Sekretion der Mamma). *Deutsche Gesellschaft. f. Gynäk.*, Halle, 1913, May.

By Zentralbl. f. d. ges. Gynäk. u. Geburtsh. s. d. Grenzgeb.

The author comes to the conclusion that early removal of the breast in young lambs does not produce any appreciable influence upon the development of the animal as a whole, or upon any system of organs, especially the genitals, and has no effect upon heat, pregnancy and labor. The breast, therefore, cannot be considered an organ of internal secretion. The injections of mammary extract also did not lead him to suspect the presence of an internal secretion. The author's experiments confirm those of Fedoroff, Adler, Schiffman and Vystavell, in that an inhibition of the ovarian function follows the injection of mammary extract, even up to complete cessation of menstruation in woman, but it is doubtful if this action is specific for mammary extract. Different observations lead to the supposition that other organic extracts possess a toxic action. The action is probably due to substances of the nonlactating breast, which physically do not enter the circulation, and are absorbed only during lactation, when they are able to produce their inhibitory action upon the ovaries.

Ssinoserski: Paget's Disease (Zur Frage der sogen. Pagetschen Krankheit der Brustdrüse). *Chir. Arch. Welfaminowa*, 1913, xxix, 336.

By Zentralbl. f. d. ges. Chir. u. i. Grenzgeb.

The treatment consisted of 96 applications of Finsen light, which produced no improvement. Röntgen therapy produced some healing. After three years of rapid advancement with some calcareous deposits, the breast was removed and the axilla cleaned out. Healing followed. After a careful microscopical examination the author arrived at the conclusion, that it is impossible to differentiate between the so-called Paget's disease and the squamous-celled carcinoma which develops on the base of a chronic inflammatory condition.

HESSE.

Epstein: Amputation of the Intrascapular Thorax (Zur Frage der Amputatio interscapulothoracica). *Chirurgia*, 1913, xxxiii, 344.

By Zentralbl. f. d. ges. Chir. u. i. Grenzgeb.

This operation is one of those severe surgical attacks which are but rarely executed. According to accurate statistics compiled by Nedsjesliki, there are 128 cases reported in the literature, with defi-

nite data for prolonged observation. Thirteen patients died as the result of the operation. The combined statistics are as follows: death due to operation, 12 per cent; recurrence, 32 per cent; cures lasting less than a year, 39 per cent; and cures lasting longer than one year, 17 per cent. These figures are not so bad as they seem, since many of the cases date back to the pre-antiseptic age. The author observed five cases, three of which have previously been reported, all ending in recovery.

Two types of operative procedures are employed for these cases; one school (Pozzen, Tullio, Degenello, Owrtnchnikoff) employing a conservative method, endeavoring to accomplish their purpose with resection, and the other school (Nancrede, Ajello, Prianischnikoff, Berger, etc.) employing a radical method, removing the entire extremity and shoulder girdle. The author proposes a procedure based on the manner of spread of these tumors by the lymph and blood-stream of the shoulder. The operation consists in the removal of half of the shoulder girdle, the scapula and clavicle and resection of the humerus; the upper extremity can, however, be saved. According to this method a woman, forty-five years old, was operated. She had a tumor the size of a child's head involving the left scapula. At the operation the scapula and the acromial end of the left clavicle were removed. After several plastic operations the patient was discharged with a dragging shoulder, but a functionable hand and forearm. She died later from a severe paraproctitis and sepsis. The tumor proved to be a sarcoma.

SCHAAACK.

Carson: Interscapulothoracic Amputation of the Shoulder. *Ann. Surg.*, Phila., 1913, lvii, 796.

By Surg., Gynec. & Obst.

Carson states that this operation is indicated in a great many cases and done in a very few, judging by the number of cases reported. The conditions demanding such an operation are:

1. Traumatism of the shoulder, including gunshot wounds.
2. Cases of extreme bone disease of the shoulder and upper arm.
3. All cases of sarcoma of the shoulder and arm, except possibly those of giant-celled sarcoma limited to the lower two thirds of the humerus.
4. All cases of carcinoma involving the upper half of the arm, and in some cases of carcinoma of the breast, where the axilla and arm are involved.
5. Some cases of tuberculosis.

Radical amputation should be insisted upon just as soon as a positive diagnosis of sarcoma is made.

Keen thinks it possible that when the disease has invaded the medullary canal, operation may already be too late on account of the physiological fact that the bone marrow has a share in the production of the red blood cells.

Notwithstanding the fact that the operation is a long and tedious one, the mortality is only about 4 per cent in tumor cases and 25 per cent in traumas. The chief dangers are due to hæmorrhage and shock. The hæmorrhage may be very materially limited by tying the axillary artery and vein, a procedure which is made comparatively easy by resecting a part or all of the clavicle as recommended by Le Conte. Carson does not think this procedure necessary unless the clavicle be diseased and states that in his experience the difficulties of the operation are very much lessened by first dividing the pectoral muscles from above downward as close as possible to their origin, for the reason that it is very easy to include the artery and vein in the clamps applied to the muscles, and afterwards resecting the middle third of the clavicle either without removing the periosteum, where the clavicle is not involved, or subperiosteally where the clavicle is involved. Having done this, the subclavius muscle and fascia covering the vessels and nerves should be carefully divided and drawn outward, thus fully exposing the vessels and nerves. The artery should be tied first, the limb elevated until it is blanched and the vein tied. By this procedure much blood is saved.

By blocking the nerves, shock may be lessened or even prevented in some, though not in all, cases, depending somewhat on the amount of hæmorrhage. Ether by the intratracheal insufflation method is the anæsthetic of choice since it seems to limit shock and diminish post-anæsthetic effects.

In traumatic cases infection plays a very important rôle, yet this is not necessarily a fatal complication since Treves operated on such a case on the battle-field and complete recovery resulted. The two cases reported by Carson — one with epithelioma following an old extensive burn of the arm; the other a round-celled sarcoma of the arm, probably arising from the periosteum — made good recoveries. If after these patients are up and about they complain of lopsidedness, an artificial shoulder and arm, properly fitted, will relieve this very annoying condition.

HARVEY B. MATTHEWS.

Sternberg: Indications and Technique for Artificial Pneumothorax in Pulmonary Tuberculosis (Zur Frage der Technik und Indikation des künstlichen Pneumothorax bei Lungentuberkulose). *Verhandl. d. wiss. Ver. d. Ärzte d. städt. Obuchow-Krkh., St. Petersburg*, 1913, xx, 127.

By Zentralbl. f. d. ges. Chir. u. i. Grenzgeb.

The author draws conclusions from forty-three cases treated by means of artificial pneumothorax. Puncture is to be preferred to open operation. The dangers of gas embolism can easily be overcome if manometer readings are carefully made. The advantages of puncture are less trauma and fewer

chances of infection, as well as a higher percentage of successful results. The author succeeded in producing pneumothorax in all his cases in spite of the ease with which the opening healed. Future inflations with gas must be governed strictly by the individual cases regarding the amount and the time intervals in order that the condition of the patient may not be seriously disturbed.

The author divides the indications into two groups. To the first belong cases of advanced unilateral involvement, which offer a poor prognosis, and above all those cases of diffuse unilateral aspiration pneumonia following hæmorrhage, and followed by high temperature with little tendency towards resolution. The second group constitutes a relative indication and consists of cases in which toxæmia has subsided but with marked unilateral anatomical changes, cases with small but rapidly advancing lesions and cases with brisk and frequent hæmorrhages. Contrary to Forlanini, the author does not consider the establishment of pneumothorax advisable in incipient cases of tuberculosis since these respond well to other methods of treatment and since the production of pneumothorax is usually followed by hypertrophy of the right heart. Pneumothorax is contraindicated in advanced bilateral cases and in those complicated by cardiac and renal conditions.

VON SCHILLING.

Sternberg: Artificial Pneumothorax for Pulmonary Hæmorrhage (Über künstlichen Pneumothorax bei Lungenblutungen). *Verhandl. d. wiss. Ver. d. Ärzte d. städt. Obuchow-Krkh., St. Petersburg*, 1913, xxii, 34. By Zentralbl. f. d. ges. Chir. u. i. Grenzgeb.

This is a report of two cases of pulmonary hæmorrhage with a hopeless prognosis. After a total injection of 1500 cc. of nitrogen, the hæmorrhage was controlled. The temperature fell from 39° C. to normal in a short time and the general condition was good.

VON SCHILLING.

PHARYNX AND ŒSOPHAGUS

Biggs: Cast of Epithelial Lining of the Œsophagus from a Case of Chloroform Poisoning. *Proc. Roy. Soc. Med.*, 1913, vi, Laryngol. Sect., 123.

By Surg., Gynec. & Obst.

The patient drank and vomited one ounce of chloroform. On the third day she vomited the cast. Treatment with bismuth carbonate, lanoline and paroline accompanied by rectal feeding was continued thirteen days. Œsophagoscopy three months later revealed no tendency of the œsophagus to contract.

EARLE B. FOWLER.

Torek: The First Successful Case of Resection of the Thoracic Portion of the Œsophagus for Carcinoma. *Surg., Gynec. & Obst.*, 1913, xvi, 614.

By Surg., Gynec. & Obst.

After reviewing the causes of failure in the operation for carcinoma of the œsophagus, Torek describes the method of operating by which he succeed-

ed in overcoming certain difficulties and avoiding certain dangers of intrathoracic resection of the œsophagus. He calls attention to Sauerbruch's view that only the carcinomata near the neck or near the cardia should be resected, and that the carcinomata in the middle portion should be left untouched. In contrast to this the author states that the carcinomata near the cardia are not only rarer than those in the middle portion but are also more frequently associated with inoperable metastases. The carcinomata in the middle portion therefore play a more important rôle in the problem of cancer of the œsophagus. Among the dangers of the operation were injury to the vagi and leakage from the oral stump of the œsophagus after resection.

The patient was a woman, 67 years old. The tumor was situated in the middle portion of the œsophagus, beginning just below the arch of the aorta and extending one and three fourth inches down. Gastrostomy had been performed some time previous; anæsthesia by tracheal insufflation was employed. An incision was made through the whole length of the seventh intercostal space, from the posterior end of which it was extended upward by cutting through the seventh, sixth, fifth and fourth ribs near their tubercles. This gave excellent access to the parts. Extensive adhesions between lung and parietal pleura were separated. The portion of the œsophagus below the tumor was lifted out of its bed after laying the vagi aside. Over the tumor the dissection of the vagi was more difficult, requiring

the division of some branches crossing it. During this procedure the pulse remained steady, between 93 and 96. The dissection of that part of the œsophagus which passed behind the arch of the aorta proved difficult. It was accomplished by dislodging the aorta after dividing a number of its thoracic branches.

The tumor was attached to the left bronchus which was cut during the process of separating the tumor from it. This was afterward sutured with silk. The dissection of the œsophagus was continued all the way up to the neck. It was divided with a cautery at a safe distance below the carcinoma after double ligation; the lower stump was invaginated and the upper brought out through an incision in the neck at the anterior border of the left sternocleidomastoid muscle. It was then placed under the skin of the chest, the cut end, after resection of the carcinoma, being sutured to an incision in the skin made for that purpose. Thus an infection of the pleura from the œsophagus was rendered impossible.

The thorax was closed without drainage. The patient made a good recovery. On the seventh day, when the last stitches were removed, the wound was completely closed. Feeding is done by introducing the upper end of a gastrostomy tube into the end of the œsophagus; when the patient swallows, the food passes through this tube into the stomach. There are several methods of œsophagoplasty that could be employed. The author urges early diagnosis and early operation.

SURGERY OF THE ABDOMEN

ABDOMINAL WALL AND PERITONEUM

Kustner: A Pedunculated Necrotic Tumor the Size of the Fist in the Region of the Umbilicus (Ein nekrotischer, über faustgrosser Tumor, welcher breit gestielt in der Gegend des Nabels sass). *Deutsche Gesellschaft. f. Gynäk., Halle, 1913, May.*

By Zentralbl. f. d. ges. Gynäk. u. Geburtsh. s. d. Grenzgeb.

A 34 year old multipara, who aborted a year previously, complained of pain in the right inguinal region. About a week later the skin in the region of the umbilicus ruptured and pus exuded. In a short time a pink tumor protruded, which later turned black.

Bimanual examination showed an empty pelvis and the uterus lying just behind the abdominal wall, which was densely infiltrated. Fever was present. The tumor was removed with a Paquelin cautery. The stalk consisted mostly of fibrous tissue and the tumor smooth muscle with some connective tissue. In two months the epithelium was entirely restored, and the infiltration of the abdominal wall disappeared. It was then discovered that the left border of the uterus was adherent to the abdominal wall in the region of the umbilicus. The histological findings as well as the fixation of the

uterus would speak more in favor of a subserous myoma of the uterus than a necrotic abdominal wall desmoid. It is not improbable that the stalk of the subserous polyp became twisted, the tumor becoming adherent to the wall of the abdomen in the umbilical region, where the rupture took place.

Machefer: Biliary Peritonitis without Perforation of the Bile Passages (Les peritonites biliaires sans perforation des voies biliaires). *Thèse de doct., Par., 1913.*
By Journal de Chirurgie.

This study is based on a personal case and on sixteen found in the literature. The author thinks the peritoneal effusion in those cases is really bile, though the macroscopical appearance is the only proof, as chemical examinations are either lacking or doubtful. He does not believe that the condition is an ordinary peritoneal collection discolored by bile resorption. The bile may reach the peritoneal cavity through an unrecognized perforation of a duodenal ulcer, through a perforation of the duodenum, the gall-bladder, or the bile ducts; or it may filter through the surface of the congested liver, or the walls of the gall-bladder. The latter is the hypothesis accepted by the author. The filtration is

supposed to take place either, through the hypertrophied mucous diverticula (canals of Luschka) or through abnormal lymphatic channels, or on account of chemical changes in the composition of the bile. Machefer agrees with authors who ascribe it to changes in the walls of the gall-bladder (sometimes caused by the Eberth bacillus), biliary hypertension due to blocking of the passages by calculi being a favoring, but not altogether necessary, factor. The real mechanism, which would account for the fact that the above-mentioned lesions are common while biliary peritonitis is so rare, is unknown.

The effusion contains, besides bile, a fluid exudate produced by the peritoneal reaction. According to the degree of septicity of the bile there is an acute peritonitis with little purulent fluid and few pseudomembranes, or a subacute peritonitis with a large amount of bile-colored serum. This effusion is always free; it collects at first on the right side; it may remain there, without any adhesions to confine it. It sometimes contains typhoid or colon bacilli.

The signs are those of a peritonitis. The onset is sudden. There is usually no jaundice as there is in biliary peritonitis following a perforation of the bile passages. The peritonitis is either acute with little effusion and a prompt fatal outcome, or subacute with a large effusion and attenuated symptoms. The prognosis is unfavorable. The diagnosis from appendicitis, peritonitis due to perforation of the bile channels and intestinal obstruction, is difficult.

The treatment is evacuation of the collection followed by cholecystectomy, or cholecystostomy when the common duct is occluded or obstructed. The post-operative treatment is that of all cases of peritonitis.

L. HOUDARD.

Clairmont and Von Haberer: Remarks on the Contribution of Prof. Nauwerck and Dr. Lübke: Does a Biliary Peritonitis Exist Without Perforation of the Bile Passages? (Bemerkungen zu der Arbeit von Prof. Nauwerck und Dr. Lübke: Gibt es eine gallige Peritonitis ohne Perforation der Gallenwege?) *Wien. klin. Wchnschr.*, 1913, xxvi, 891.

By Zentralbl. f. d. ges. Chir. u. i. Grenzgeb.

The authors reported a case of biliary peritonitis without perforation of the biliary passages, in which also the pathologist was unable macroscopically to find any perforation or even a suspicious area. Contrary to the views of Nauwerck and Lübke who consider a perforation of the bile passages as always necessary for the formation of a biliary peritonitis, the authors on the basis of the published cases come to the conclusion that the following pathological and anatomical findings are the basis of biliary peritonitis without perforation: 1. A slit-like perforation demonstrable only at autopsy is present. 2. A primary thinning of the wall (microscopically demonstrable) exists through which in all probability the bile has exuded. 3. On account of dilation of the subserous bile passages of the liver a small per-

foration has probably resulted. 4. In other cases a perforation may not be demonstrable even at autopsy, but an abnormal permeability of the walls to bile is present as in the case reported. In all these conditions the same clinical picture prevails at operation: the surgeon is unable to find the place of exit of the bile and attack it surgically.

UNTER ECKER.

Baradulin: Pneumococcic Peritonitis (Zur Frage der Pneumokokkenperitonitis). *Chirurgia*, 1913, xxxiii, 527.

By Zentralbl. f. d. ges. Chir. u. i. Grenzgeb.

In 1911, Rohr collected 189 cases of pneumococcic peritonitis from the literature. In Russia the cases have but rarely been observed and described. The author reports two cases operated upon successfully. The first patient was a girl six years old, who became ill two weeks previously with abdominal symptoms. In the left hypochondrium a fluctuating swelling developed. At the operation, after opening the peritoneal cavity, about three glasses of greenish-yellow pus were evacuated. The cavity was then tamponed. A cure resulted. The second case was a boy fourteen years old, who became ill with similar symptoms. Here also an encapsulated accumulation of pus developed, which was drained by laparotomy, and the cavity tamponed. The patient recovered.

In both cases the bacteriological examination of the pus showed a pure culture of pneumococci. The ways by which pneumococci enter the abdominal cavity are variable. In pleuroitis the pneumococci enter through the diaphragm. Pathologically and clinically two large types can be differentiated: The localized and the general or diffuse. The localized form offers a decidedly better prognosis. Both of the author's cases belong to this group. The diagnosis of a pneumococcic peritonitis is very difficult, as only general peritonitic symptoms appear. Rohr's statistics show 86.3 per cent recovery for the localized form and only 10.68 per cent for the diffuse form. The treatment, of course, must be operative and at the earliest possible moment.

SCHAAK.

Wendel: Retrograde Incarceration; "Hernia en W" (Die retrograde Incarceration; Hernie en W). *Ergebn. d. Chir. u. Orthop.*, 1913, vi, 536.

By Zentralbl. f. d. ges. Chir. u. i. Grenzgeb.

Under retrograde incarceration and "hernia en W" have been described cases in which a beginning or complete gangrene of a loop of bowel not lying within the hernial sac has occurred, the contents of the sac being entirely normal. Both terms are however not synonymous; a "hernia en W" can occur without incarceration and a retrograde incarceration can occur also in other hernias. In retrograde to incarceration of free end organs as the appendix, tube, omentum and ovary, the relations are very simple if the gangrene is easily explained as being due to partial or complete constriction of the vessels leading from the abdominal end of the organ. The condition is different, however, in the case of the bowel.

The author has collected 78 cases from the literature and comes to the following conclusions: Retrograde incarceration occurs most commonly in old people with old and large hernias. The contents of the hernia may consist of one to three separate loops of bowel, or of mesentery alone. The loops are usually incarcerated but not always. The connecting loop may be intact although the herniated loops may be incarcerated. Frequently the hernial loop is much altered and gangrene usually sets in remarkably early. The mesentery of the connecting loop may be incarcerated in the hernia or not. Even when it is not incarcerated it may show marked vascular changes which are sharply limited and may form an arcade-like figure. The genesis of "hernia en W" therefore is not identical with the genesis of retrograde incarceration. The gangrene or the nutritional disturbance of the connecting loop is due either to an incarceration of the mesentery or a compression of the same on account of tension and traction; possibly also on account of kinking of the distended connecting loop. The distention and fecal stasis with its bacterial and mechanical disturbances also can aid in the production of gangrene of the connecting loop. The author advises combining the two conditions described as "retrograde incarceration" and "hernia en W" under the term "retrograde incarceration," limiting it only to conditions in which during a hernia that loop of bowel continuous with the herniated loop shows decided nutritional disturbances, the explanation of which must be sought in the hernial relations and not purely abdominal causes.

The author then discusses the diagnosis, prognosis and treatment. He advises risking a resection rather than an enterostomy.

OEHLER.

Swetschnikow: A Case of Spontaneously Incarcerated Diaphragmatic Hernia of the Stomach, the Spleen and a Loop of Bowel (Ein Fall von spontan incarcerierter diaphragmaler Hernie des Magens, der Milz und einer Darmschlinge). *Morskoj vrach*, 1913, April, 217.

By Zentralbl. f. d. ges. Chir. u. i. Grenzgeb.

A healthy young Austrian sailor twenty-four years old, while performing some labor, was taken ill with severe pains in the epigastrium: Vomiting set in shortly after and was repeated during the next few days. The epigastrium was sensitive to pressure and rigid. During the next two days the objective findings increased. The patient passed flatus and fecal matter. Pulse 64. The tongue was moist but coated. On the third day after the onset, cyanosis of the head was present, especially of the ears. The pulse was hardly palpable on the left side; on the right it was weak, 135 per minute. The patient complained of pains in the epigastrium, especially during deep expiration. No vomiting or singultus, but marked meteorism in the upper abdomen, of the left flexure of the colon, transverse colon, ascending colon and right iliac fossa was present. The left iliac fossa was sunken and dull, whereas the other

parts were tympanitic over the lower portions of the left lung a tympanitic sound was heard, gradually merging into the stomach tympany. The abdomen was highly sensitive, rigidity marked, tongue moist and clear.

After the administration of high enemas of oil and seltzer water, a little fecal matter and much foul gas were expelled. The subjective condition improved, the meteorism decreased. The rigidity disappeared over the entire abdomen except in the epigastrium. Pulse 90. Cyanosis much less. The operation was therefore postponed. On the following day the cyanosis of the face and ears returned. Pulse 120. The abdomen was not distended or sensitive. Edge of the liver became palpable; it was soft and not sensitive. Cardiac tones clear and in normal location. The tympany over the lower edge of the left lung less marked. No vomiting, but the patient regurgitated everything that he swallowed. After another high enema some gas was expelled. The patient passed a good night. The abdomen next morning was soft and insensitive. The liver was markedly enlarged, but not sensitive. The epigastrium was not distended, but was sensitive. A swelling was observed over the 3-4 rib, internal to the left mammary line. Tympany was definite over the lower border of both lungs, more marked on left side. Cardiac dullness not definite and the impulse was absent. The patient could lie only on the left side, and regurgitated everything he swallowed. By evening the heart was pushed further to the right. The left half of the thorax was tympanitic; posteriorly the falling drop sound could be heard. Hippocratic succussion could be elicited.

A diagnosis of diaphragmatic hernia was made and the operation performed by Gerulanos. The stomach was absent from the abdominal cavity. The diaphragm on the left side was found bulging into the abdomen and tense. The edges of a tear could be palpated as firm tense bands. The abdominal incision was enlarged transversely, and the stomach punctured through the diaphragm. It became possible to introduce two fingers into the diaphragmatic wound and enlarge it. The stomach filled the entire left thoracic cavity to the second rib; adhesions had formed between it and the pleura and could not be replaced. Following a further enlargement of the diaphragm-opening the heart ceased to beat and respiration stopped. It was impossible to revive the patient. Only with difficulty was it possible to separate the stomach from its adhesions. A loop of bowel was first brought out, then the spleen, and finally the gangrenous stomach.

Important points in the differential diagnosis from other incarcerations are the cyanosis, the unequal radial pulse, the clean moist tongue, the regurgitation of the small amount of fluid without any attempts at vomiting, the tympany over the lower portions of the lungs and the displacement of the heart.

HOLBECK.

Schmidt: The Radical Operation for Intestinal Hernia with Incomplete Hernial Sac; Sliding Hernia (Zur Radikaloperation der Darmbrüche mit inkomplettem Bruchsack; Darmgleitbrüche). *Deutsche Ztschr. f. Chir.*, 1913, cxxii, 266.
By Zentralbl. f. d. ges. Chir. u. i. Grenzgeb.

Schmidt reports the history of three interesting cases observed and operated by him. He then discusses the work of Sprengel, Finsterer and Sudeck, as well as the anatomy and operative technique of these herniæ. From the results of his work he concludes that in a sliding hernia of the colon on the right side, a one-angled loop of colon is involved, whereas on the left side a two-angled loop enters into the hernia. In opening a sliding hernia extreme care must be employed, so as not to open the bowel. The reposition of such a sliding hernia must be accomplished by inversion, which is illustrated by drawings.

Superfluous parts of the free hernial sac are to be removed, but one must be careful not to divide the blood-vessels supplying the bowel. Before severing the sac it is held against the light to see if it is empty. In general its anterior and inner surface may be removed without danger, as the bowel and vessels lie posteriorly and laterally. If reposition is difficult the abdominal wall may be split in the angle of the outer part of the ring. If the spermatic cord is closely adherent to the sac it is advisable to implant the testicle into the abdomen rather than to castrate.

VON TAPPEINER.

Tate: Sarcoma of the Omentum. *Am. J. Obst., N. Y.*, 1913, lxvii, 1142.
By Surg., Gynec. & Obst.

Tate reports a case of sarcoma of the omentum and tabulates 22 cases which he finds in the literature to date. His patient was a male, 32 years of age, who had a left inguinal hernia for years which had required the use of a truss. The rupture had occasioned no particular discomfort until three months previously, when it had begun to produce some pain. In the few weeks prior to operation the hernial mass had started to increase in size, so that for these two reasons the patient was operated. At operation the mass was the size of a cocoanut and was composed of omentum in which was embedded the testicle and cord. There was also a considerable amount of paraffin in the sac which had been injected two years previously by some one for the attempted cure of the hernia. The mass with testicle and paraffin were removed and the hernia repaired. The microscope showed the mass to be a round-celled sarcoma of the omentum, while the testicle was normal. The patient was seen 18 months later and had a large secondary growth in the abdomen, but refused further operative attention.

N. SPROAT HEANEY.

Benedict: Chylous Cyst of the Mesentery. *Surg., Gynec. & Obst.*, 1913, xvi, 606.

By Surg., Gynec. & Obst.

The author supplements Friend's list of 53 cases in the issue of the same journal for July, 1912.

Excluding duplicates, the list is brought up to 96 cases although Benedict had previously excluded four in Friend's list as probably pseudo-chylous and thinks that a few more may be so or that duplications may exist on account of listing under different names. He carries the literature back to Poncy, Jr., 1699, and adds four other cases antedating Rokitsky's report of 1842, commonly regarded as the beginning of the history of this condition. There seems to be no sex or age predilection and the prognosis is surprisingly good: 60 recoveries, 14 deaths, 10 unspecified results after operation and 12 cases diagnosed at necropsy, some of the last having lived for years with the tumor.

Aspiration was performed in 5 cases; drainage, mainly after preliminary incision in 24, some form of enucleation or resection in 31; and marsupialization in 4. The result appeared to depend not on the method of operation, but upon the condition of the patient, i. e., whether he had an occlusion of bowel, peritonitis, sepsis, etc.

Drummond: The Surgical Aspects of Persistent Meckel's Diverticulum. *Surg., Gynec. & Obst.*, 1913, xvi, 656.
By Surg., Gynec. & Obst.

The paper is based upon a review of the surgical records of the Royal Victoria Infirmary, Newcastle-upon-Tyne, extending over a period of twelve years.

There were twenty-two cases of acute abdominal disease resulting from a persistent Meckel's diverticulum, seven of which became inverted into the small intestine and produced intussusception — making 7 per cent of all the cases of intussusception from January, 1900, to June, 1912. Intestinal obstruction due to acquired adhesions occurred in 6 cases. In two cases there was strangulation of the small intestine over the diverticulum, which was adherent to the umbilicus. In another case in which the diverticulum adhered to the umbilicus, a secondary volvulus of the lower ilium, cæcum and ascending colon occurred. In the remaining six cases there was evidence of inflammatory change in the diverticula.

An attempt is made to show that, speaking generally, a certain type of diverticulum is responsible for a definite and specific lesion. A Meckel's diverticulum of unusual length (6 or 8 inches) in addition to causing intestinal obstruction may be inflamed or strangulated as the result of interference with its blood supply by a loop of implicated small intestine. Diverticula adherent to the umbilicus may cause strangulation of the small intestine, or produce a secondary volvulus. The small cone-shaped diverticula become inverted into the bowel and produce intussusception.

The lesions are considered under three headings; viz., obstruction, inflammatory conditions and more rare forms such as enterocysts, calculi, etc., though not infrequently the pathological condition cannot be classed under one of these headings. One case is recorded of an intestinal obstruction, gangrene of the Meckel's diverticulum and a calculus.

In dealing with the differential diagnosis of the lesions produced by Meckel's diverticulum, appendicitis is stated to be the most frequent source of error. The reason that lesions of Meckel's diverticulum are confounded with appendicitis is that both organs are capable of undergoing the same pathological changes; e.g., peritonitis, obstruction, inversion, harboring of calculi, etc. Other lesions, such as pathological conditions of the gall-bladder and intestine may be confounded with Meckelitis.

GASTRO-INTESTINAL TRACT

Borchgrevink: Acute Dilatation of the Stomach and Its Treatment. *Surg., Gynec. & Obst.*, 1913, xvi, 662. By Surg., Gynec. & Obst.

The author reports five cases successfully treated by abdominal posture. He thereupon gives a review of 137 cases published since Schnitzler's introduction of the postural treatment in 1895. Of thirty-one cases not treated or medically only, twenty-nine died. Of 48 cases, treated by stomach tube, 24 recovered. Of 23 operated cases, 5 survived, 1 after gastro-jejunostomy, 1 after gastrostomy and 3 after their non-incised stomachs had been emptied during laparotomy. Of 26 cases treated by abdominal posture, 2 died, one from the gastric dilatation and one after the condition had been cured by the postural treatment. In two of the cured cases, the abdominal position was little used and seemed to be without effect. In the other 22 cured cases, the abdominal posture more often in the presence of threatening symptoms, and partly, when longer treatment by the stomach tube had been without result, has brought about a noticeable and often a surprising effect. In three cases, which were laid on the right side, the effect was excellent. Lying on the left side did not have any decided effect.

Considering the etiology of acute gastric dilatation, Borchgrevink draws the following conclusions, which are based partly on the good results obtained by abdominal posture. 1. The dilatation primarily occurs as a sequel of overloading of the stomach, either by excess in food or fluids, or by stagnation of the contents of the stomach and following gastric hypersecretion. 2. The dilated stomach produces the arterio-mesenteric occlusion of the duodenum as it compresses and empties the small intestine, and, increasing in size, pushes it into the pelvis, thus tightening the root of the mesentery. 3. By abdominal posture the arterio-mesenteric compression is relieved and the stomach allowed to empty its contents into the bowel.

Heyrovsky: Histological Examination of the Mucosa in Ulcer and Carcinoma of the Stomach (Histologische Untersuchungen der Magenschleimhaut bei Ulcus ventriculi und Carcinom). *Deutsche Ztschr. f. Chir.*, 1913, cxxii, 359.

By Zentralbl. f. d. ges. Chir. u. i. Grenzgeb.

Detailed examinations in 120 cases gave the following results: In more than half a decided gastri-

tis was found. In gastric ulcer accompanied by gastritis no definite cause for the latter was made out. No change in the fundus glands, characteristic of hypersecretion and hyperacidity was demonstrated. The follicular erosions found commonly in ulcer probably are important in the formation of ulcer. The ulcer patients with gastritis after an anastomosis had more gastric disturbances than those without a gastritis. The staining technique and the literature on the subject are appended. THIEMANN.

Grüber: The Relations between Carcinoma and Peptic Ulcer on the Upper Digestive Tract (Beitrag zur Frage nach den Beziehungen zwischen Krebs und peptischem Geschwür im oberen Digestionstrakt). *Ztschr. f. Krebsforsch.*, 1913, xiii, 105. By Zentralbl. f. d. ges. Chir. u. i. Grenzgeb.

The article contains the statistical investigations on the results of about ten thousand post-mortems in regard to the frequency of peptic ulcer of the œsophagus, stomach and duodenum on the one hand, and carcinoma on the other. Furthermore, it gives a detailed description of the microscopical and macroscopical findings of several interesting cases, with a thorough discussion. The author comes to the conclusion that the statistical findings at post-mortem show absolutely no point in favor of the contention that carcinoma develops particularly on the basis of a peptic ulcer. The views of Payr and Küttner based particularly upon surgical material are criticized as lacking convincing proof. The histological proof of the development of carcinoma on the basis of ulcer, according to the author, is found only rarely. The clinical as well as the anatomical methods of investigations cannot feasibly be employed, as correct statistical information is not available. MEYER.

Seidel: The Perforated Gastric Ulcer (Über das perforierte Magengeschwür). *Zentralbl. f. Chir.*, 1913, xl, 910. By Zentralbl. f. d. ges. Chir. u. i. Grenzgeb.

Seidel reports twenty-five cases of perforated gastric ulcers which were operated upon with a mortality of 28 per cent. It is most important to close the perforation perfectly and this is effected in the best way by placing auxiliary sutures parallel to the border of the perforation. On these auxiliary sutures the real closing sutures find a secure hold. Gastro-enterostomy was as a rule not added (only in one case); it offers, when performed later on, much better prospect for a good healing. KINDL.

Palfrey: The Administration of Ox Bile in the Treatment of Hyperacidity and of Gastric and Duodenal Ulcer. *Am. J. Med. Sc.*, 1913, cxlv, 796. By Surg., Gynec. & Obst.

This report embodies the results of treatment of fifty cases of the most common form of dyspepsia characterized by "sour stomach," "heart burn," or pain after eating. A review of the physiology of the pylorus shows that the control of the pyloric

sphincter depends upon the degree of alkalinity and acidity in the duodenum. When the duodenal contents are alkaline the pylorus opens, when they are acid it closes. No degree of acidity on the gastric side can cause the pylorus to open.

According to Pilcher, the acid contents of the duodenum are neutralized by the bile and pancreatic juice as well as by the duodenal secretion.

This action may be enhanced by the administration of ox bile per os.

The bile pills are prepared after the directions of Pfaff, each pill containing 0.25 gram of dried ox bile and coated with solol to conceal taste and prevent dissolution in the stomach. Two or three pills are given three times a day for a week; the number is then reduced.

As the author states, this report is preliminary, but the results obtained in fifty cases are worth reporting.

H. A. POTTS.

Mayo: Palliative Operations for the Relief of Incurable Carcinoma of the Stomach. *St. Paul M. J.*, 1913, xv, 269. By Surg., Gynec. & Obst.

A high percentage of individuals with cancer are incurable when they present themselves for examination and only in a certain percentage is a palliative operation indicated. In performing a palliative operation the surgeon assumes a great responsibility. He must be quite sure that the palliation will be sufficient to repay the patient for the expense and suffering and for time spent in the hospital, and he should take into consideration that in the background is an unenlightened public opinion to be influenced by success or failure. Palliative operations are indicated for the relief of one or more of several conditions which may develop in the gastro-intestinal tract, the most common of which is obstruction. A differential diagnosis cannot always be made between malignant and benign ulcerations unless a specimen be removed for microscopic examination. Moreover, when a specimen is obtained for examination it may be taken from a point near but not actually a part of the disease and thus give an incorrect version of the pathology. If a specimen cannot be obtained and a diagnosis is made on the clinical findings only, the patient should be given the benefit of the doubt and the condition treated as though it were benign.

Twenty-two patients who recovered from a palliative operation performed in the clinic for clinical or doubtful cancer of the stomach, and whose after-history was traced, lived more than one year. Fifty per cent lived from one to five years; the others died supposedly from malignant disease. Cancer in the vicinity of the cardia, producing obstruction, occurs in about 10 per cent of the cases of gastric cancer. Gastrostomy is a useful means of palliation in these cases and should not be delayed to the last resort. The Witzel method of operation is ordinarily performed, but the Stamm-Kader technique is equally effective. A number 16 English catheter is used. Gastro-enterostomy is a

satisfactory palliative procedure in cases of inoperable malignant obstructions of the pylorus and for those cases having huge excavations in the posterior wall of the stomach which are usually carcinomatous but occasionally benign. If the tumor be large and more or less fixed, as it usually is in inoperable cases, anterior gastro-enterostomy after the Wolfer-Hartmann method gives excellent results. The posterior method is used for less extensive growths and in cases in which the clinical diagnosis between cancer and ulcer is questionable. Jejunostomy is especially useful in cases of extensive involvement when a doubt as to the diagnosis exists. It is also useful in cases of accidental perforation of the ulcer. The gastric tumor should be removed even though all of the glands cannot be extirpated. It gives longer and more comfortable existence to the patient.

Clement: Occlusion in a Bilocular Stomach (Occlusion aigue dans un estomac biloculaire). *Marseille méd.*, 1913, iv, 248. By Journal de Chirurgie.

The woman, 32 years old, entered the hospital with cyanosis, breathing irregularly and vomiting a greenish bile-stained liquid continuously. This condition had lasted fifteen days and began very suddenly. On examination the abdomen was found to be distended and tympanitic, especially in the upper part. A solid immobile mass was palpated in the left hypochondrium, which did not correspond to any organ.

On opening the abdomen an enormously distended stomach came into view; it was so distended that the wall was transparent. Examination disclosed a bilocular stomach, the opening between the two parts being so narrow that fluid could not pass. A gastro-enterostomy was performed and an adhesion to the ilium freed. The patient died six hours later. At autopsy there were no signs of ulcer, active or healed, or of new growths about the stomach.

The absence of scars made it seem that the constriction must have been either a congenital affair or due to very early ingestion of some caustic. On account of the condition of the patient it was impossible to get a history of any previous attacks. The author believes that the trouble of fifteen days duration must have been due to a spasm from a long standing hyperchlorhydria or from a lesion in the innervation of the stomach. Such cases are very rare and the diagnosis from intestinal obstruction high up is hard to make.

J. DUMONT.

Balfour: Anterior Gastro-Enterostomy. *Ann. Surg., Phila.*, 1913, lvii, 902.

By Surg., Gynec. & Obst.

It is generally conceded that when a gastro-enterostomy is indicated, the posterior no-loop operation is safer, gives the best end-results, and that it carries practically no risks of unfortunate mechanical sequelæ. The method has been so consistently satisfactory that it may have been used at times when other methods would have sufficed as well or

perhaps better. It is particularly applicable for benign lesions in the region of the pylorus when a resection of the pyloric end of the stomach is not indicated or a plastic operation is not possible.

For various reasons an anterior gastro-enterostomy is the operation of choice in certain definite groups of cases, the largest of which is composed of the obstructions of the pylorus due to carcinoma in which a resection of the growth is not feasible. In many of these cases the mechanical obstruction with its retention of decomposed food products and the starvation is the important factor. Not only are these patients greatly relieved temporarily by drainage of the stomach but the terminal stages of the malignancy are much less pitiable. It is particularly in this type of case that the anterior method is preferable on account of the speed, safety and simplicity with which it can be performed. A smaller group is composed of certain benign lesions at or near the pylorus where a posterior gastro-enterostomy would be desirable but not possible because of the presence of some mechanical condition. Extensive adhesions, congenital or inflammatory, malformations, etc., may be sufficient to preclude the advisability of attempting the posterior method, and yet permit the anterior operation to be done safely and quickly.

Goullioud: Simultaneous Resection of the Stomach and Transverse Colon; Five Cases (*Réséction simultanée de l'estomac et du colon transverse; 5 observations*). *Lyon chir.*, 1913, ix, 475.
By Journal de Chirurgie.

The nearness of the colon to the stomach makes it possible for new growths of one organ to invade the other and so make resection of both necessary. Leriche has collected thirty-two such cases, with ten deaths. The author had but one operative fatality in his five cases. He removed the tumor of the stomach and colon in one mass and then made a gastro-duodenostomy and lateral anastomosis of the colon.

In one case there was a myosarcoma of the stomach invading the meso-colon so that it could not be removed without destroying the blood supply of the colon. The tumor, with parts of the stomach and 30 cm. of the colon was removed and the continuity of the gastro-intestinal canal brought about as described above. The patient died of pneumonia eight days later.

In the second case a cancer of the stomach was resected with some of the colon, a gastro-duodenostomy and a lateral anastomosis of the colon performed. The patient died eleven months later of recurrence in the pleura and supraclavicular lymph glands. In the third case 16 cm. of the stomach and 25 cm. of the transverse colon were resected for an abscess about a gastric ulcer in a woman 62 years old. The patient recovered and was in good health fifteen months later.

In the fourth case the cancer of the colon was resected and twenty months later it was necessary to resect 15 cm. of the pyloric part of the stomach

and 12 cm. of the intestine. The patient recovered and was in good health nine months later, three years after the first operation. In a second case of a woman 53 years old who had had painful attacks for fifteen months, a cancer of the colon and stomach was resected *en masse* and the patient was in good health six years and three months after the operation.

Momburg: Lacing and Closing of the Pylorus with Omentum (*Umschnürung und Verschluss des Pylorus durch Netz*). *Deutsche med. Wchnschr.*, 1913, xxxix, 1096.

By Zentralbl. f. d. ges. Chir. u. i. Grenzgeb.

In operating on his last two cases of duodenal ulcers Momburg proceeded in the following way: He first closed the pylorus with a silk ligature; in the furrow thus formed he pulled a piece of the omentum behind the pylorus upwards placing it around the pylorus. He fastened this omental ring with two or three sutures.

One of the patients died five days after the operation from pneumonia and at the autopsy it was found that the omental ring closed the pylorus perfectly and tightly. Momburg believes that the omentum alone will hold the pylorus closed after the silk thread ligature has been cut.

KOLB.

Haenel: Duodenal Ulcer (*Über das Ulcus duodeni*). *Zentralbl. f. Chir.*, 1913, xl, 912.

By Zentralbl. f. d. ges. Chir. u. i. Grenzgeb.

The author discusses the symptoms and diagnosis of duodenal ulcer. He believes that operation is indicated in the early stages of the duodenal ulcer, when all internal therapeutic measures fail; operation is further indicated in hæmorrhages, symptoms of stenosis, and, above all, in perforation of the ulcer, which is the most dangerous complication and occurs in about fifty per cent of all cases. The direct method of operation consists in the excision of the duodenal ulcer, invagination and suture, but has the disadvantage, that the cause of the evil, i. e., the influence of the gastric juice upon the duodenal wall, is not eliminated and new ulcers may form. According to the author the method of choice is the gastro-enterostomia retrocolica posterior with closure of the pylorus.

Haenel has performed gastro-enterostomy nineteen times in twenty-six cases of duodenal ulcer during the last eight years (in five cases with closure of the pylorus). Twice he excised the ulcer and in one case added gastro-enterostomia retrocolica posterior. In five cases of perforation the ulcer was sutured four times. Two patients with perforated ulcer died.

HARF.

Berard and Alamartine: Accidents and Technique of Jejunostomy (*Accidents et technique de la jéjunostomie*). *Rev. de chir.*, 1913, xlvii, 660.

By Journal de Chirurgie.

The authors report the case of a man 50 years old suffering from a diffuse cancer of the stomach with

reflex œsophageal dysphagia. A jejunostomy was performed according to the technique of Witzel-Eiselsberg. As the patient was normal for the first three days and the œsophageal spasm had ceased, he was allowed fluids by mouth. On the fourth day the abdomen became tense and there were colicky pains but no vomiting; the patient became rapidly worse and died that evening. At autopsy, a sharp kink was found in the jejunum and the jejunum and duodenum proximal to the jejunostomy were dilated. Liquids passed readily as soon as the mouth of the jejunostomy was freed.

To avoid a recurrence of this accident a jejunostomy in omega (Albert and Mayo-Robson) is now practiced. They searched the literature to find the technique of a jejunostomy which most closely fitted the following requirements: it must be simple and rapid as the patient is usually cachectic; the opening must be continuous and readily closable; finally there must be no danger of obstructing the intestine.

The method of Albert and Mayo-Robson with a lateral or button anastomosis of Jaboulay-Lumiere appeared to be the best.

The authors advise local anæsthesia preceded by the injection of scopolamine and morphine. A median or lateral oblique subumbilical incision is made, and anastomosis without sutures using the Jaboulay-Lumiere button is performed. A lateral jejunostomy is then made at the middle of the loop according to Toutan.

J. OKINCZYC.

Viguiér: 1. Volvulus of the Cæcum, Ascending Colon and Initial Portion of the Transverse Colon; Death from Intestinal Hæmorrhage. 2. Volvulus of the Pelvic Colon Treated by Simple Untwisting; Recurrence, Resection of the Affected Loop; Cure (Volvulus du cæcum du colon ascendant, y compris l'angle hépatique, et de l'origine du colon transverse; mort par entérorragie. Volvulus du colon pelvien, traité par la détorsion simple; récidence vingt mois après; résection de l'anse colique; guérison). *Bull. et mem. Soc. de chir. de Par.*, 1913, xxxix, xxii, 952.

By Journal de Chirurgie.

Viguiér's first case was that of a soldier, 25 years old, who was suddenly seized with violent pain above and to the right of the navel, accompanied by vomiting. Next morning, the vomitus was brownish, the paroxysmal pain remained in the same point, the abdomen was distended, the pulse 130 and thread-like. Neither gases nor stool had been passed during the night. Immediate laparotomy, 17 hours after the onset of the symptoms, showed a volvulus of the cæcum and whole ascending colon which dragged with them the terminal portion of the small intestine and the hepatic flexure and initial portion of the transverse colon. The torsion was complete (360°) and clockwise. Untwisting and restoring the gut to its normal position led to a partial emptying of the incarcerated gas and fecal matter, but the patient died on the operating table.

At autopsy the mucosa, from the duodeno-jejunal angle downward, was studded with minute

hæmorrhagic spots, which became larger and more marked as one came nearer the large intestine, so that in the terminal portion of the ileum the mucosa was intensely congested, dark purple with black patches. These lesions stopped abruptly at the site of the torsion where the mucosa resumed its normal appearance. The cause of death was intestinal hæmorrhage, the twisting of the mesenteric vessels having resulted in a huge hæmorrhagic infarct in almost the whole of the gut.

In the second case, that of a woman 42 years old, the first attack of volvulus of the pelvic colon was treated by laparotomy, puncture of the gut with a trocar to do away with the enormous distention and untwisting. The torsion was at least twice 360° and reversely clockwise. Recovery was uneventful, but 20 months later there was a recurrence, less severe than the first attack. The torsion was only 180° and in the same direction as formerly. Resection and end to end suture brought about a cure.

The author, whose opinion is concurred in by LEJARS, thinks that resection, preferably in the interval, or at the time, of the operation for obstruction, if the general condition of the patient permits, is the only radical treatment; untwisting leads to recurrence and anchoring of the loop yields only poor results.

HARTMANN quotes a case with multiple recurrences, finally cured by resection.

DELBET has operated on two cases of volvulus of the large intestine, one in a child 7 years old. Untwisting was immediately followed by an extremely copious evacuation, but death occurred in a few hours. The second, in a man 50 years old, was treated by untwisting and anchorage. The man recovered but could not be followed.

ROBERT once reduced a volvulus very easily, but the gut was already markedly altered at the point of torsion and leakage caused death. Resection would have been the correct procedure in this case.

SOULIGOUX has recently treated a volvulus by simple untwisting; the general condition was such that nothing more would have been possible.

TUFFIER has seen a case where, after multiple recurrences yielding to non-operative treatment, an artificial anus had to be made during a more severe attack. The patient died in a few hours.

SAVARIAUD has seen six cases of acute volvulus of the small intestine, all ending fatally. He noted also a case of chronic volvulus of the large bowel in which simple untwisting brought about recovery, but since the first attack, recurrences have twice necessitated surgical interference.

J. DUMONT.

Kellogg: Incompetency of the Ileocecal Valve; Disorders Arising from this Condition and Their Treatment. *Med. Rec.*, 1913, lxxxiii, 1105.

By Surg., Gynec. & Obst.

The study of the ileocecal valve and its disorders has been greatly neglected. The author studied sixty cases, and the most common symptoms were constipation, marked gastric pain, obstinate indi-

gestion, flatulence, etc. A large percentage showed evidence of appendicitis, colitis, mental and nervous depression.

The treatment is divided into the palliative and the operative. The former consists in securing at least three bowel movements daily and in changing the intestinal flora by administering cultures of several varieties of bacteria (*B. bulgaricus*, *B. bifidus* and *B. glucobacter*). The increased bowel activity is obtained by bulky laxative diet with the addition of agar-agar and paraffin oil if necessary; gymnastics, outdoor life, cold bathing, etc., all assist. The results have been most satisfactory, and the operative procedure has been resorted to only when it was necessary to enter the abdomen for some other pathological condition.

The operation consists in restoring to normal the partial intussusception of the small bowel into the cæcum. This is easily done by pushing the small intestine into the cæcum for a short distance and fixing it by a couple of sutures passed through the outer coats of the gut and it is often best to narrow the aperture between the lips of the valve by constricting the outer layers of the gut with a suture or two. The competency of the valve is then tested.

J. H. SKILES.

Obál: Primary Typhlitis (Primäre Typhlitis). *Beitr. z. klin. Chir.*, 1913, lxxxiv, 201.

By Zentralbl. f. d. ges. Chir. u. i. Grenzgeb.

The cæcum used to be looked upon as the seat of origin for all inflammatory processes occurring in the ileo-cæcal region. At present there is a difference of opinion as to whether such a condition as primary typhlitis occurs at all. The author reports a case from the surgical clinic of the University of Budapest which is an undoubted example of typhlitis without appendicitis. The patient was a young man with an abscess in the ileo-cæcal region. Operation revealed a large perforated ulcer in the anterior surface of the cæcum, though the appendix was perfectly normal. These observations were confirmed by microscopical examinations of sections of the ulcerated area as well as of the appendix. The possibility of specific disease, as typhoid or tuberculosis, were carefully excluded.

With this case and the observations of other authors to support his views, the author concludes that primary typhlitis certainly does occur. It can hardly be differentiated, however, from the much more frequently occurring appendicitis. The infection arises from the faecal contents of the bowel. Congenital and acquired changes of the cæcum are to a certain degree predisposing factors. DENCKS.

Sonnenburg: Pathology and Therapy of Perityphlitis (Pathologie und Therapie der Perityphlitis). Leipzig: Vogel, 1913.

By Zentralbl. f. d. ges. Chir. u. i. Grenzgeb.

Sonnenburg's new book is thoroughly revised and all extraneous matter excluded. In regard to appendicitis the entire treatment is concise and

thorough. Sonnenburg's personal note on the value of the blood-picture with all its consequences is clear and concise. In this connection he states: "We possess to-day sufficient diagnostic aids to make a diagnosis and render a prognosis and to differentiate the cases (especially in the acute stage to differentiate the mild from the severe cases). The proper interpretation of the blood-picture is often the deciding factor for action, as it shows us the virulence of the infection and the involvement of the peritoneum in the individual case." In another place he continues: "As long as in an acute attack of appendicitis, the peritoneum is not involved and the inflammatory condition, usually catarrhal in nature, is confined to the lumen of the appendix and probably associated with an enteritis or colitis, so long is there no reason to treat this condition differently from the way in which the same condition in other parts of the intestinal tract would be treated, i. e., with laxatives." VERTH.

Lardennois and Okinczyc: The "Y" Cæco-sigmoidostomy (La typhlo-sigmoidostomie en Y) *J. de chir.*, 1913, x, 538. By Surg., Gynec. & Obst.

The authors present the following procedure as a more logical, a technically simpler and a more efficacious method of "short circuiting" the large intestine for grave chronic obstruction or rebellious

Fig. 1. Showing result to be avoided. The Y is inverted due to the excessive length of the sigmo-sigmoid segment. The section of the colon has been made too low and the two anastomoses are too close together.

Fig. 2. Approximation of the sigmoid to the cæcum. The cæcum has not yet been resected. The end of the sigmoid has been freshened by cutting with scissors below the occluding clamp.

colitis. After various experiments in cæco-sigmoidostomies, the authors finally arrived at the following perfected operation:

The patient is placed in the Trendelenburg position and a long median incision is made from the pubes to the umbilicus. The colon is rapidly explored for the clinical lesions and the termination of the small intestine inspected for the only possible contra-indications to this operation — namely, a stenosing band across the ileum.

1st Step. The cæcum and sigmoid flexure are brought well up into the wound. This is easily accomplished as lesions for which the operation is indicated are usually accompanied by a mobile cæcum.

2nd Step. This consists in the approximation of the mesenteries and the closure of the button-hole formed by the mesentery, the posterior parietal peritoneum and the pelvic mesocolon. This is done following Lane's technique: Beginning with the right surface of the mesocolon, a suture is "run" from the sigmoid to the posterior parietal peritoneum at the sacral promontory and thence to the left surface of the mesentery close to its termination. Great care is exercised to avoid blood-vessels. The two ends of the suture are held in a clamp and are not tied until the anastomosis is completed.

3rd Step. Appendectomy is performed quickly as the appendix interferes with the anastomosis.

Fig. 3. Showing the correct result. Approximating suture below the sigmo-sigmoid implantation to fix the angle of the Y.

4th Step. An intestinal clamp is placed above the bottom of the cæcum to mark the limit of the cæcum which is to be resected.

5th Step. After milking away the contents, two intestinal clamps are placed on the sigmoid. It should be cut high enough toward the colon to make the right cæco-sigmoid branch a little longer than the left colon sigmoid branch in order to leave some distance between the two anastomoses. If the colon loop is too long, the Y will be inverted, which might lead to a vicious circle (Fig. 1). The two clamps should include most of the depth of the mesocolon and the extremities should be in apposition.

6th Step. The iliac sigmoid is now cut between the clamps, the cut surfaces being cauterized. The mesocolon is cut to the end of the long clamp and immediately sewed over to control hæmorrhage. The upper extremity of the cut colon is wrapped in saline gauze and laid aside.

7th Step. The inferior end of the sigmoid is placed in apposition to the cæcum and the posterior layer of serous sutures is passed. (Fig. 2.)

8th Step. The anastomosis between the cæcum and sigmoid is completed, both sigmoid and cæcum being cut across just proximal to the sealing clamps before the sutures are passed.

9th Step. The compresses are removed from the superior end of the cut sigmoid and, after choosing a point far enough from the cæcal anastomosis and at the same time high enough so that the work can

be done outside the abdomen, the sigmoid-sigmoidostomy is done in the usual manner. This presents no particular difficulty as patients for whom this operation is indicated usually have a long sigmoid.

roth Step. The suture as passed in step two is now tied just tight enough to close the opening in the mesentery and the operation is terminated by replacing the intestines and closing the abdomen. The result obtained is represented schematically by Fig. 3.

ELLIS FISCHEL.

Heile: The Origin of Inflammations in the Appendix on the Basis of Bacteriological and Experimental Evidence (Über die Entstehung der Entzündungen am Blinddarmanhang auf bakteriologischer und experimenteller Grundlage). *Mitt. a. d. Grenzgeb. d. Med. u. Chir.*, 1913, xxvi, 345.

By Zentralbl. f. d. ges. Chir. u. i. Grenzgeb.

In the course of inflammations of the appendix variable processes, bacterial and mechanical, are usually present. The important question as to which process induced the inflammation remains unsolved. The presence of bacteria even in the earliest stages does not clear up the etiology any further. Even though the bacteria must be considered as the causal factors of the later inflammation, mechanical factors are nevertheless contributory.

From animal experimentation the author concludes that the advancing destructive inflammation of the appendix with secondary peritonitis is caused by the action of toxic substances formed by the retention of the contents of the appendix. The toxins arise on the one hand from a variety of bacteria which in themselves are not pathogenic, and on the other hand by changing the media in which they grow. The destructive inflammation of the appendix therefore is not an infectious disease. This is further proven by the fact that bacteria are never found in the circulating blood and secondary metastatic abscesses are never developed. All prophylactic measures must be based on the fact that the inflammation is due to an intoxication. It is of importance not only to prevent the retention of substances but also to influence that which has been retained. Incompletely split up albumen is very dangerous as it may enter the appendix in the change from a diarrhoea to constipation.

Rjesanoff: Anatomical Consideration of Ligamentous Formations About the Proximal End of the Large Intestine; Ligamentum Variforme (Schwartige Ablagerungen in der Gegend des proximalen Abschnittes des Dickdarms als anatomisches Gebilde; Ligamentum varioforme). *Chirurgia*, 1913, xxxiii, 126.

By Zentralbl. f. d. ges. Chir. u. i. Grenzgeb.

This article represents an extensive anatomical study — an original investigation on many cadavers. It was the author's purpose to study the normal conditions of these membranous formations, and therefore only those cadavers were selected which presented absolutely normal abdominal findings. Ninety-three bodies were studied. Five distinct

types are described according to the manner in which the peritoneal membranes are disposed. 1. When they are extensive, they envelop the gall-bladder and cover the ascending colon as far as the cæcum. In these cases the membrane appears much like a continuation of the small omentum. 2. The ligaments cover the ascending colon, the cæcum and possibly the appendix. 3. These are cases in which the peritoneal folds affect only the cæcal region, the appendix being frequently attached to the cæcal wall. 4. Rare instances in which the ligamentous folds begin in the right abdominal wall, extend across the cæcum and ascending colon and blend with the great omentum. These formations are described also as ligamenta cæco-parietale and ligamenta mesenteric-parietale. 5. To the last group belong those cases in which the floor of the cæcum is fixed in an unusual position. Many of the above classified peritoneal folds have been previously described under various names, for example, ligamentum felleocysticum-pylorocolicum (Huschke and Luschka) more recently by Jonnescu in 32 per cent, Ancel and Sencert in 58.7 per cent.

In all individuals presenting any of these conditions, certain other peculiarities can be detected in the abdomen. The description of these constitutes another chapter of the article. The great omentum shows an abnormally large development. The descending colon is often under-developed. The sigmoid is usually fixed in the left iliac fossa. The mesentery of the small intestine is unusually wide at its attachment. The course of the mesenteric vessels also is peculiar. The results of these investigations are tabulated and well illustrated by thirty-five drawings. The peculiarities in the development of the bowel are also discussed.

After quoting the literature extensively and going into the subject in detail, the author concludes that there is a close connection between the embryonic development of the gut and the later development of the peritoneal folds or membranes. His opinion is supported by personal observations on fourteen embryos between the ages of one and five months. The single cases of varying peritoneal folds are discussed in detail and well illustrated. In conclusion the author again points out that membranous developments about the proximal end of the large gut are not looked upon as the result of inflammatory processes, as surgeons frequently assert, but that we have here to deal with anatomical structures which have a developmental history of their own. Since these structures possess an embryological development of their own and can therefore vary widely, the author has proposed the name "ligamentum varioforme."

SCHAAACK.

Goldthwait: Orthopedic Principles in the Treatment of Abdominal Visceroptosis and Chronic Intestinal Stasis. *Surg., Gynec. & Obst.*, 1913, xvi, 587.

By Surg., Gynec. & Obst.

The work of the orthopedist in these cases consists in the modeling of the body so that the common

deformities of flat chest and the narrowed upper abdomen, with the acute angle at the costal border, with the hyperextension of the lower spine, the forward protrusion of the head, the marked relaxation of the abdominal wall, etc., can be overcome.

It is impossible for the viscera to work correctly unless they can be put in their normal position and in the extreme type of congenital visceroptosis the space in the upper abdomen does not exist if the patient has reached the age of maturity. It is essential in these cases to remodel the body so that the ribs are flared and the space in the upper abdomen restored to its normal shape and size. In this way the abdominal wall will be tightened and the strain upon the muscles will be lessened and their tone restored. In the mere remodeling of the body the organs naturally sag back more nearly into their normal positions, even without any artificial support. Artificial support is, of course, needed in the extreme cases to maintain the poise until the muscles and ligaments can have gained their proper tone.

The aim which the orthopedic surgeon has in mind is to make the poorly nourished, badly poised, inefficient, visceroptotic type of individual, strong well poised and vigorous. Postures, both when standing and lying down, braces, exercises, stimulating bathing, massage,—all have their place in bringing about this remodeling. In such position or with such postures and as a result of the natural improvement with the viscera, frequently the intestinal stasis or difficulty in the evacuation of the bowel is very much lessened, if not wholly controlled.

Such a restoration of the poise and proper contour of the body produces free circulation in the spinal cord and the natural improvement in the nervous and mental vigor of the individual. With such an understanding of the problem the author feels that the prognosis in most of these cases is good, even though the degree of visceroptosis is extreme.

Maylard: Abdominal Incisions and Intestinal Anastomosis in the Treatment of Carcinoma of the Colon. *Glasgow M. J.*, 1913, lxxix, 401.

By Surg., Gynec. & Obst.

Maylard emphasized the advisability of certain incisions and methods of intestinal anastomosis for carcinoma of the colon. He advocates either transverse or oblique incisions; that is to say, incisions are transverse in the mid and upper abdomen, oblique in the lower. Vertical incisions he uses only for diagnostic purposes. He prefers the transverse and oblique incisions first, because they effect the freest possible exposure, and therefore admit of free removal of diseased bowel, and second, because they result in cicatrices that are least likely to weaken and cause herniæ. In the case of tumor or stricture of transverse colon, the incision is carried across the abdomen from one to two inches above the umbilicus. The recti muscles are divided if necessary and no untoward effects accrue if the rectus sheath is secured in front and behind the muscles; a secure and non-giving cicatrix results.

In case the hepatic or splenic flexures are involved, or the ascending or descending colon, transverse incisions are carried outward from points situated respectively above and to the right or left of the umbilicus. The great advantage of these incisions lies in the anatomical fact that there is no cross division of the muscle or aponeurotic fibers. In case of involvement of cæcum, lower part of ascending colon, lower descending colon, the iliac colon, or the pelvic colon, an oblique iliac incision is best.

The success in intestinal anastomosis depends upon two essential conditions. First, the healthier the bowel edges along the line of union the more rapid and secure the healing. It is largely because of the unhealthy condition of the bowel edges that failure so commonly occurs when anastomosis is attempted under conditions of acute obstruction. The second consideration is the perfect coaptation of uninterrupted serous surfaces. The author prefers "end to side" anastomosis, with invagination of proximal segment, where excision does not interfere. As the great danger in colon anastomosis lies in the divided meso-colon, with its lacteals and lymphatics serving as an atrium of infection, it was the author's aim to obviate this condition by his invagination anastomosis. Maylard further recommends forcible dilatation of the anus to allow expulsion of gas and thereby prevent strain on suture line of anastomosis.

R. W. McNEALY.

Turnure: Gas Cysts of the Intestine. *Ann. Surg.*, Phila., 1913, lvii, 811. By Surg., Gynec. & Obst.

Turnure gives a synopsis of the forty-nine reported cases with a report of his own case. He states that intestinal pneumatosis is a chronic, probably self-limited process, consisting of the formation of gas cysts, which may occupy any layer of the intestinal wall. The gas acting as a foreign body gives rise to inflammatory changes and leads to the formation of giant cells. Furthermore that thirty-five out of the forty-four cases show the presence of gastric or duodenal ulcers or at least symptoms pointing to some chronic disease of the intestinal tract of years' standing.

The views of the origin of intestinal pneumatosis vary widely, but may be grouped as follows:

1. The gas-forming bacterial theory which is endorsed by the majority of observers.
2. The mechanical theory, in which the process is entirely analogous to that of traumatic emphysema; viz., that the intestinal gas escapes from minute ruptures in the bowel wall.
3. The neoplastic theory in which the gas cysts are considered as new growths, the center of which have undergone degeneration, followed by liquefaction and the formation of gas.
4. The chemical theory in which the coli ærogenes group of bacteria is thought to form the cysts.

A summary of the chief characteristics of the lesions found by Turnure is as follows:

1. Extensive gas cyst formation, situated for the most part outside the longitudinal muscular coat.

2. Characteristic appearances of the gas cysts and cyst walls, in which an endothelial lining and giant cells are a feature.

3. Occurrence of spaces or channels, some of which may be lymphatics partly lined by endothelium and partly filled with giant cells, endothelioid cells and leucocytes.

4. Evidences of dilatation of lymphatics and of the inter-communication of large lymphatic spaces, possibly cyst spaces, with undoubted lymph channels.

5. Absence of communication between cysts.

6. Inflammatory and productive processes between the cysts and under the peritoneum, resulting in the formation of connective tissue and fibromatous masses, leading to the obliteration of certain cysts and therefore to a kind of healing process.

7. Absence of bacteria in most of the cysts.

8. The deposition of highly refractive needles in the interior of many cysts, causing a peculiar flattening of the cells of the lining membrane, and the possible rôle of such crystalline matter in the production of some of the giant cells.

Thus Turnure concludes from the reported cases and from a study of his own that the condition is self-limited with a tendency to spontaneous cure.

HARVEY B. MATTHEWS.

Brown: The Value of Complete Physiological Rest of the Large Bowel in the Treatment of Certain Ulcerative and Obstructive Lesions of This Organ, with Description of Operative Technique and Report of Cases. *Surg., Gynec. & Obst.*, 1913, xvi, 610. By Surg., Gynec. & Obst.

Brown points out in his paper the advantages of complete physiological rest of the entire large bowel in the treatment of certain diseases of this organ which have heretofore been treated by various surgical methods. He describes a technique by which this rest can be accomplished, and how, when its purpose is fulfilled, the bowel can be put back into commission in a manner both safe and satisfactory. The type of cases in which the author has found this surgical rest treatment of value are enumerated as follow: (1) Mucous colitis associated with obstructive lesions; (2) ulcerative colitis (amœbic, bacillary, tuberculous, etc.); and (3) obstructions to the colon, acute and chronic, due to neoplasms.

In mucous colitis Brown's technique seems better to meet the indications than Lane's operation, or the Weir-Mitchell treatment, etc. By it all pericolic bands and adhesions can be severed, the cæcum elevated from the pelvis and the intestinal stasis immediately relieved. The entire colon can be put at rest and during this process of complete physiological quiet, the patient can be given the benefits which follow dietetic, hygienic and orthopedic treatment. In this way the bowel can be given a chance to regain its normal tone.

Technique: Through a right rectus incision sufficiently long for general exploratory purposes, the abdomen is opened. The cæcum is at once

sought and the entire large bowel is carefully examined. All pericolic adhesions are severed, the appendix removed and the stump buried. The ileum is next severed between two clamps, close to the ileocæcal valve. The distal ileum is tied off and buried as was the appendix. At a suitable part of the cæcum, a purse-string suture of linen is placed and the cæcum is next incised. Through this incision, a large catheter is inserted after which the purse-string is tightly tied. A second purse-string of No. 1 chromic catgut is next placed. Under the loops of this purse-string, three long catgut fixation sutures are placed. A stab-wound is next made at McBurney's point and the catheter and fixation sutures are pulled through. The peritoneal surfaces of the cæcum surrounding the catheter are next scarified. The catheter is now slipped through the button and the fixation sutures threaded through the eyes and tightly tied, thus closely approximating the serous surfaces of the cæcum to the parietal peritoneum. A stiff rubber drainage tube is next inserted into the proximal ileum, fixed with a double purse-string suture and brought out of the lower angle of the rectus incision. The parietal peritoneum is made to hug it snugly by a few catgut sutures and the abdominal wound is closed in the usual way.

The indications for restoring the continuity of the large bowel are (1) improvement of the patient's general condition and the return to normal, as shown after repeated chemical, microscopical, and culture growth examination of irrigation fluids passed. This restoration should not be made too early, particularly in the ulcerative lesions of the colon. To put the organ back into commission, restoration is readily accomplished by simply cutting out the anus and closing the distal ileum with a purse-string suture. A lateral anastomosis of the ileum to the ascending colon may be preformed or the ileum switched into the sigmoid (Lane). The author has never found any difficulty in restoring the continuity of the intestine.

The author bases his paper upon ten cases so operated. Two were cases of chronic intestinal stasis, with obstructions due to pericolic bands and flexures; both are greatly improved and now comparatively well. Three were operations for amœbic dysentery; all cases were cured. One ulcerative colitis with extensive involvement of the sigmoid and rectum; patient now in good health. One case of extensive obstructive tuberculous colitis; patient received great relief and lived in comfort for two months. Three were late and inoperable malignancies; one lived six months, one five months. The third is still living, nine months after operation and is comfortable and in reasonably good health.

Rosenheim: Colitis Chronica Gravis (Über Colitis chronica gravis). *Deutsche med. Wchnschr.*, 1913, xxxix, 989.

By Zentralbl. f. d. ges. Chir. u. i. Grenzgeb.

The difference between colitis gravis and simplex is only one of degree. In all cases a definite inflam-

matory condition of the mucous membrane exists, followed usually by erosions and tumor-like formation. Fistulae and abscesses may develop as secondary complications. Somnolence, colics, endocarditis, multiple neuritis, etc., are due to a general intoxication. A specific symptom complex does not exist. The prognosis is always doubtful. Rosenheim observed three deaths (peritonitis, sepsis and general cachexia) in his series of fifteen cases.

Rest in bed, bland diet, opium, tannin, bolus alba, bismuth, etc., frequently accomplish much therapeutically. A local treatment of the colon is impossible in many cases on account of the sensitiveness. The insufflation treatment is of no value. Irrigations with boric acid and tannic acid are of value in mild cases only. Enemata of starch, gelatine and gum arabic appear to be of more value. Surgical treatment should then be considered only when internal therapy has proved futile, but under certain conditions it may be a life-saving procedure. Special indications for surgical intervention are prolonged fever, progressive emaciation, marked discharge of pus in the faeces and local or general complications.

WOLFSOHN.

Graham: Report of a Case of Faecal Tumor Associated with Hirschsprung's Disease. *Tr. Am. Proctol. Soc.*, 1913, June.

By Surg., Gynec. & Obst.

Graham reports a case of faecal tumor with Hirschsprung's disease, which was that of a young French woman, aged twenty-seven, who had undergone three abdominal operations. Present illness dates from birth. Not unusual to go a week or ten days without a stool, and then evacuation was produced only by means of enemata.

At the age of 19, she was operated upon and a large faecal tumor was removed from the sigmoid. At the age of 25, she suffered another attack of complete intestinal obstruction. She was operated upon again, and this time a large faecal tumor was removed.

In August, 1912, for the third time, she presented symptoms of complete intestinal obstruction for seven days. Abdomen enlarged and general tympanitis except in the lower right quadrant, where there was a dull area corresponding to a large tumor, which could be readily palpated. The tumor, a faecal mass, was exceedingly hard and did not pit on pressure. It could be easily moved in every direction throughout the abdomen. Attacks of violent, colicky pains were frequent. Vomiting was persistent, pulse 120, temperature 101° F. She requested that the faecal tumor be removed, but refused to give her consent to any short-circuiting or resection of the bowel.

At operation the tumor was found in sigmoid. Its greatest circumference was 19¾ inches; its weight was 64 ounces. The dilatation which was confined to the sigmoid was very marked, the greatest circumference being 20 inches. Patient made an uneventful recovery, and was discharged from the

hospital on the tenth day. She gained in weight, and appeared to be in the best of health. She experienced no difficulty in procuring daily evacuations with the aid of small doses of cascara. On December 15, 1912, she was doing nicely. Information was received later that she was operated upon April 19, 1913, and died three days after.

Von Beck: Late Conditions after Exclusion of the Colon by Means of Ileosigmoidostomy (Spätzustände nach Dickdarmausschaltung durch Enteranastomos zwischen Ileum und Flexura sigmoidea Ileosigmoidostomie). *Beitr. z. klin. Chir.*, 1913, lxxxiv, 338. By Zentralbl. f. d. ges. Chir. u. i. Grenzgeb.

Von Beck reports his results in fifty-two cases of colon exclusion by means of ileosigmoidostomy performed for chronic ulcerous colitis (26), chronic pericolicitis and displacement (6), extensive tuberculous of the bowel (10), and for inoperable colon carcinoma (10). Three cases died during the first four weeks after the operation (peritonitis, pneumonia, thrombosis); in the remaining forty-nine cases a good functional anastomosis resulted, no bad effects following the short circuiting. The length of life of the carcinomatous patients after operation was four to twelve months. Excellent end results were obtained in the tuberculous cases, even in extensive involvement of the lower ileum, caecum and colon.

These cases were operated in two stages; in the first, the diseased area was extirpated, the ascending colon tied off and the ileum was anchored anteriorly to the abdominal wall; after four to six weeks the ileum was sutured to the sigmoid and the tuberculous ascending and transverse colon were then excluded. Results: One death, three years after operation, from tuberculous infection of the bowel, the colon, however, being normal; two deaths, six and eight years, respectively, after operation of pulmonary phthisis, colon entirely normal. Of the remaining seven cases, six are well and able to perform their daily duties (four to ten years after operation). Of the thirty-two cases operated for colitis, pericolicitis and displacement, six cases returned in from one to five years complaining of gradually increasing obstipation, relative obstruction or retrograde peristalsis. All were women. In three of the cases an appendicostomy had been performed and irrigation treatment employed ineffectively. In three cases a secondary operation was necessary on account of retrograde peristalsis, saccular dilatation of the rectum, faecal accumulation to the middle of the transverse colon and spasms in the ileum and jejunum. In these cases the author recommends the exclusion of the colon by means of ileosigmoidostomy with invagination of the distal end of the ileum into the caecum. In cases of spasm and retrograde peristalsis—peculiar to the female sex—he advises making an end to end anastomosis between the ileum and sigmoid and anchoring the upper end of the sigmoid outside as a mucous fistula or extirpating the colon at a later date.

BLEZINGER

Libensky: The Initial Stages of Atypical Neoflexure in the Rectum and the Sigmoid Flexure (Die ersten Anfänge der atypischen Neubildung im Rectum und im S. romanum). *Ztschr. f. klin. Med.*, 1913, lxxvii, 355.

By Zentralbl. f. d. ges. Chir. u. i. Grenzgeb.

The author has observed two cases of recurrent adenoma of the sigmoid flexure and their metaphysis into atypical new growths. He reports a number of similar cases from literature and emphasizes the importance of rectoscopy on account of the uncertainty of the symptoms. Eight autopsies are reported from the author's own observations and he points out that the condition of the pedicle of the adenomatous polyps is of special prognostic importance. Only polyps with thin pedicles may be considered benign. Broad pedunculated polyps necessitate the extirpation of the entire base of insertion to prevent recurrence.

HELLER.

Baermann and Heinemann: Treatment of Amoebic Dysentery with Emetin (Die Behandlung der Amöbendysenterie mit Emetin). *München. med. Wchnschr.*, 1913, lx, 1132.

By Zentralbl. f. d. ges. Chir. u. i. Grenzgeb.

The authors experimenting with emetin from different manufacturers furnishing samples of varying strength found that the drug was very toxic for amoebæ. When injected subcutaneously, or better still, intravenously, most of the organisms—and in especially favorable cases, all of them—in the intestinal wall and in the ulcerated areas were killed. After 10–70 days a few organisms may again be found. There are, however, strains of amoebæ which evidently withstand the effects of emetin. Cysts do not seem to be directly affected by it though its early use will possibly intercept their formation. With the use of emetin even in the severest cases prompt healing takes place in the ulcerated areas of the bowel.

The maximum intravenous dose is 250 mg. per 60 kg. body weight. The best results were obtained by the following method: 1–2 intravenous injections with 100 ccm. physiological NaCl solution, or the subcutaneous injection of 150–200 mg. followed after 8–10 days and at intervals of 2–3 days, according to the condition of the stools, by 4–5 subcutaneous injections of 100–120 mg. Where necessary a similar course of treatment may be repeatedly given at intervals of 3–4 weeks.

VERTH.

Proust: Rectal Prolapse Treated by Colopexy and Peri-anal Wiring; on the Coexistence of Rectal and Genital Prolapse; on Hystero-colopexy (Prolapsus du rectum traité par la colopexie et le cerclage de l'an; de l'association des prolapsus rectaux et génitaux; de l'hystéro-colopexie). *Bull. et mem. Soc. de chir. de Par.*, 1913, xxxix, 657.

By Journal de Chirurgie.

Proust's patient, a woman 48 years old, whose prolapse dated back 8 years, had previously had a supravaginal hysterectomy. Laparotomy showed a very deep Douglas pouch which was obliterated. The

sigmoid loop was anchored, above the uterine stump, to the remnants of the round ligaments and to the peritoneal covering of the bladder. Two months later, a peri-anal wiring was made to correct a tendency to eversion of the anal mucosa. A year after the operation, there is a slight abdominal eventration; the prolapse remains cured; the silver wire is still unbroken.

QUÉNU, commenting on this report, points out the influence hysterectomy may have on the development of rectal prolapse. The uterus and rectum have common means of suspension; therefore, any cause bringing about the fall of one endangers the fixity of the other. Hysterectomy deprives the rectum of the anterior support afforded it normally by the uterus. The weakening of the pelvic floor favors the prolapse of both organs. Hence the not infrequent association of rectal and genital prolapse and the wisdom of anchoring both the rectum and uterus when colopexy is resorted to. In a case of large prolapse, Quénu first sutured the vaginal vault to the rectum; next he stitched the upper edges of the broad ligaments to the posterior peritoneum on each side of the gut; and finally laid the sigmoid loop crosswise and anchored up to the left iliac fossa, where a small slit was made in the posterior peritoneum. The tendon of the lesser psoas muscle was bared and the bowel stitched to it. The uterus, from the cervix to the fundus, was also sutured to the anterior abdominal wall. In younger women this total hysteropexy would be replaced by a shortening of the round ligaments.

LENORMANT states that the association of rectal and genital prolapse, though not uncommon, is far from constant. To the giving way of the pelvic floor, which undoubtedly is a potent predisposing cause, must, however, be added an abnormal length and mobility of the pelvic colon. This explains why, while genital prolapse is so common in women, rectal prolapse is almost as rare in females as in males, and also why, in large rectal prolapse, colopexy is a necessary adjunct to perineorrhaphy.

Lenormant always uses the Quénu-Duval technique for colopexy, oftentimes supplementing it with a Thiersch peri-anal wiring. The latter operation alone is an excellent palliative procedure in cases in which a major operation is contra-indicated; it is sometimes sufficient in children. Lenormant has performed colopexy 9 times for large prolapses. Out of 5 cases that could be followed, 2 had rapid recurrences, 3 are cured after 4½, 7 and 8 years.

MAUCLAIRE has performed three colopexies after hysteropexy or colpoperineorrhaphy. He had one operative death; one case could not be followed; the third is perfectly well 18 months after the operation.

J. DUMONT.

MacLaren: Rectal Section for Pelvic Abscess in Men. *J.-Lancet*, 1913, xxxiii, 254.

By Surg., Gynec. & Obst.

The author opens the paper with a report of a case. A boy, 12 years old, was brought to the

hospital three days after the onset of appendicitis. The appendix had ruptured. He was immediately operated and much pus was found in the abdomen. Two drains were inserted, one to the bottom of the pelvis and the other to the base of the appendix. He did not improve very much following the operation. On the tenth day following the abdominal section he was very sick, having a pinched, drawn face and a rigid, much distended abdomen. His operative wound was discharging considerable pus. He complained of a great deal of pain. His anus was widely open, the anterior wall bulging, and the peritoneal cul-de-sac was distended to its utmost by a collection of pus which filled the pelvis. The sac was opened with a sharp pointed scissors, using them as a dilator. At least a quart of serous pus came away first, followed by thick, foul, colon pus. A winged rubber tube was inserted. His improvement was very rapid.

In the hands of the author, rectal section for the drainage of pus in the pelvis has proven a life-saving measure. The results are immediate and brilliant. As the operation is so simple it is hard to understand why there is so much prejudice by so many surgeons against doing it. A second abdominal operation in these cases is so frequently followed by death that the author now hesitates to perform it and does a rectal section instead. Since the institution of the method his mortality rate has been considerably reduced. This method of treatment is especially adaptable to those cases of appendicitis with abscess formation which occur in young children. It may be used as preliminary operation in those cases which reach the surgeon exhausted and very septic and with large abscesses in the pelvis. If after opening the rectum the patient does not immediately improve, the abdomen should be opened.

EDWARD L. CORNELL.

Deloire: Autoplasty with Flaps of Fat in Anal Fistula (De l'autoplastie graisseuse dans la fistule anale). *Bull. et mem. Soc. de chir. de Par.*, 1913, xxxix, xxi, 889. By *Journal de Chirurgie*.

In extra-sphincteric anal fistula, non-tuberculous, incision or even extirpation of the fistula is insufficient, because the perirectal fat has disappeared and the cavity does not fill up. On the other hand, any method dividing the sphincter would result almost with certainty in faecal incontinence.

In such a case, the writer dissected and extirpated the fistulous tract. The bottom of the wound was bounded by the left side of the rectum. Six months later, the cavity was still $1\frac{1}{4}$ to $1\frac{1}{2}$ inches deep and wide enough to admit a pencil. Then a cutaneous flap was cut from the left thigh, the subcutaneous fat being carefully preserved; the pedicle was rotated so as to bring the flap in the wound created by the freshened edges of the cavity. The skin was sutured to the skin, while the fat went to fill the perirectal gap. The result was all that could be desired.

J. DUMONT.

Barnes: A Method of Operating on Fistula without Cutting Muscular Tissue. *Tr. Am. Proctol. Soc.*, 1913, June. By Surg., Gynec. & Obst.

This method is used in those cases of fistulae which involve the sphincter muscles. An incision is made external to the sphincter, similar to that made when incising an ischio-rectal abscess. Through this opening the scar tissue is dissected out up to the internal opening. An incision is then made at the skin margin, so that the middle of this incision passes through an imaginary longitudinal line drawn from the internal opening. A submucous dissection is then channeled out up to the internal opening. Gauze drainage is kept in this until the external wound is healed sufficiently. Then the submucous tract, which remains, is incised under local anaesthesia. No muscular tissue having been cut, the function of the sphincters is preserved intact.

Zobel: A Further Consideration of Sir Charles Ball's Operation for Intestinal Hæmorrhoids. *Tr. Am. Proctol. Soc.*, 1913, June.

By Surg., Gynec. & Obst.

In every instance in which the essentials of Ball's technique have been followed out carefully, the author's results have been exceedingly satisfactory.

After a trial of this operation, the author sums up his conclusions as to its value as follows: That, as a modification of the old ligature operation, it is better than the latter, and at the same time is far superior to the clamp and cautery operation, in that it takes care of and avoids the recurrence of that revolut anal skin ring which generally becomes markedly oedematous immediately after these operations, leaving behind skin tags after the swelling subsides.

Murray: Further Observations on Pruritis Ani; Its Probable Etiologic Factor; Results of Treatment. *Tr. Am. Proctol. Soc.*, 1913, June.

By Surg., Gynec. & Obst.

Murray finds no reason for materially modifying his former reports, but has gathered data which has helped to prove the correctness of his previous work. He found streptococcic infection in three cases of pruritis ani and vulvæ, and in four cases in which the anus and the scrotum were involved. These complicated cases, with the exception of two vulva cases, improved by the use of the vaccine treatment.

In the past year Murray has increased his former series of thirty-two cases, by twenty-five, in five of which streptococcic infection was not found. These cases showed other infections, which still further proves the coccigenous nature of pruritus ani, and demonstrates also that other bacteria than streptococci may bear a causal relationship, as was hinted in the author's first paper on this subject. His cases, so far as he has been able to determine, have not been affected by diet. Since he discovered the infection in pruritus ani he has never changed the diet of any patient; neither has he restricted them in the smoking or drinking habits. The improvement

under the vaccine treatment, without regard to eating, drinking, or smoking, gives him additional proof for the bacterial theory.

During the past year Murray has carefully investigated the itching to discover whether it extends into the anal canal beyond Hilton's white line. He found that only in one instance did it extend beyond that point, and then only for a short distance. His investigations have given him additional proof that pruritus ani is not caused by any local lesion within the anal canal, and that when such lesions exist with pruritus ani they are coincidental. In the cases operated for local lesions, the pruritus ani has not been permanently improved as a result of the operative procedure.

Murray states that rectal and general surgeons have observed many cases of fistulæ with discharges upon the anal skin, not accompanied by pruritus ani. The same is true of hæmorrhoids, constipation, and other rectal lesions, pruritus ani occurring in only a small proportion of such cases. Murray, therefore, still holds that when pruritus ani exists in connection with other lesions it is a coincidence. In his 1912 report he gave a summary of nine hundred consecutive rectal cases wherein this fact was established fairly well.

The author refers to the opsonic index, or, more properly, the coefficient of extinction of opsonins, and claims that much valuable information is to be gained by this test. His work shows that if a complicating infection exists and other bacteria than streptococci are found to be the sole invading organisms, we must use the corresponding autogenous vaccine. The opsonic index, following a bacterial diagnosis, is the proper method for determining this.

The results of treatment and the history of patients prove to him that if pruritus ani exists with local lesions which demand operation, the prognosis depends upon whether a skin infection is present or not. If the skin infection is present the local lesions may be cured by the operation, but the patient should not be led to believe that the pruritus ani also will be cured by it. Per contra, if a skin infection does not exist with a local lesion and itching, the prognosis may be that it is very probable that the itching will cease with the cure of the local lesion.

After personal investigation in treating; watching results; noting how cause, effect, and results dovetail together; comparing these investigations with statements and theories made in textbooks, and in articles appearing from time to time in medical journals, containing no definite pathology or scientific reasons for cause and effect, Murray cannot understand how the profession will uphold such theories in preference to the bacterial theory which has been so well proven in his own cases and confirmed by other observers.

The uniformity of the bacteriological findings is a strong support for the bacterial theory of the etiology of pruritus ani. The chronicity of all the cases; the uniformity of symptoms; the similarity of

the conditions of the skin; the locality; the regularity as to the time of attacks; the uniformity of itching outside of Hilton's white line; the uniformity of the blood findings as to the coefficient of extinction of opsonins, and the fact that all local applications which have given beneficial results in the past have contained a strong germicide,—all point directly to a common cause. Further confirmation is found in the uniformly good results of treatment with autogenous vaccine of the variety of bacteria against which the patient has a low phagocytic power, and in the lack of good results by the various haphazard methods of treatment in general vogue.

Endo's medium is used to plate the cultures. The vaccine employed is of the strength of one billion to the cc., beginning with two minims, or one hundred and thirty millions.

Murray's references to fissures in previous papers having been misunderstood by some, he desires to state that he had referred only to fissure-like cracks of the skin and not to anal fissures or ulcers.

LIVER, PANCREAS, AND SPLEEN

Opokin and Schlamoff: Hemostatic Effect of Muscle Tissue in Injuries of the Liver (Zur Frage der blutstillenden Wirkung der Muskeln bei Leberverletzungen). *Arb. a. d. chir. Klin. d. Prof. S. Fedoroff a. d. milit. med. Akad., St. Petersburg, 1913, vii, 91.* By Zentralbl. f. d. ges. Chir. u. i. Grenzgeb.

In the past few years the efforts at hæmostasis in injuries of the liver have tended toward a new direction. An attempt is being made to stop the hæmorrhage by covering the surface of the liver with living tissue by plastic operation. To this class of work belong the unsuccessful experiments and clinical observations on transplantations of the omentum (Loewy, Boljarski, Hesse), the more recent attempts at fascia transplantation (Kirschner, David), and, lastly, the efforts of Læwen to cover the bleeding surface with muscle tissue. These experiments were performed only on rabbits, and give rise to the following queries: 1. Has the muscle tissue hæmostatic properties, or does it simply act as a mechanical tampon? 2. To what extent can plastic work with muscles be employed in hæmorrhages from parenchymatous organs? 3. How is the hæmostatic influence of muscle tissue to be explained?

To answer these questions the authors performed experiments on dogs. The muscles used were the rectus, or preferably the gluteus maximus. The muscle tissue was divided into thin slices, and preserved in warm salt solution while the wound in the liver was produced. It was made as large as possible without removing much liver tissue. The areas varied in size with that of the dogs, from 2 x 4.5 to 3.5 x 12 cm. Bleeding was profuse, but was rapidly checked by the implantation of the muscular flap, and finally stopped entirely. The fixation sutures had little to do with checking the hæmorrhage, but the muscular flap does act to some extent as a tampon. Twelve dogs were used for the

tests. Four died of peritonitis in from two to five days, two of pneumonia after one and three weeks. The rest were killed at varying intervals, three months being the longest period of observation. Microscopic examination in the early cases showed round cell infiltration in the transplanted muscle and in the later ones connective tissue change. In three cases the flap became necrotic and sloughed out. Secondary hæmorrhage did not occur.

The best part of the paper is devoted to a discussion of the thrombokinetic action of muscles. According to Loeb (1904) muscle extract possesses exceptionally strong blood-clotting qualities. To satisfy themselves on this point the authors experimented with extracts of the muscle, lung and liver of five rabbits, testing the thrombokinetic action in vitro. The technique followed was that of Prof. Slowzoff. The results showed that lung extract possessed the strongest blood-clotting properties, and that of muscle alone, the second. Liver extract possesses but slight clotting power.

After further theoretical discussion the authors conclude that the transplantation of muscle tissue into wounds of the liver for hæmostatic purposes deserves increased attention, especially from a biological standpoint.

SCHAAK.

Norris: Solitary Cysts of the Liver. *Ann. Surg., Phila.*, 1913, lvii, 805. By Surg., Gynec. & Obst.

Norris states that true solitary cysts of the liver of non-parasitic origin are rare lesions as compared with other conditions found in and about that organ. Many reported as such have been congenitally dilated gall-bladders or ducts, cystadenomata, or true cystic livers and not true single cysts. These cysts may be intra- or extra-hepatic and of any size up to several liters content, and they occur more frequently on the under surface of the right lobe of the liver. They are more common in the female and late middle life. The causation of these cysts may be summed up as follows:

1. Confluence from cystic degeneration or occlusion of aberrant bile-ducts.
2. Degenerative changes in nævi; these are usually small.
3. Cystic changes in an adenoma of the bile-ducts, usually large.
4. In the case Norris reports, infarct, a possible cause.

Moschcowitz, in 1906, said that these cysts were associated with congenital anomalies in other parts of the body, especially cysts of the kidney. That this is not necessarily so has been proven by the fact that they have been found unassociated with other anomalies.

Certain definite changes take place in the cysts of long standing, such as calcareous infiltration, numerous blood vessels; and they are usually surrounded by a firm fibrous capsule, the inner surface is smooth, often ridged and of an opaque white color. In places the wall may be so thinned as not to show this characteristic appearance. The con-

tents vary. Usually colorless fluid fills the cavity, although there may be bile or blood-tinged fluid. Albumin is present; in some cases bile pigment, blood, hæmatoidin, cholesterin and tyrosin have been found. Microscopically the capsule is composed of laminated fibrous tissue which may contain bile-ducts sometimes dilated. Occasionally blood pigment is found between the bundles of fibrous tissue. The fibrous tissue invades the liver tissue for a short distance and is lined internally with a layer of epithelial cells, which may be columnar or polyhedral in the small cysts.

As these cysts do not give symptoms until they are of sufficient size to cause pressure they are usually diagnosed post-mortem. They may be mistaken for a distended gall-bladder, cystic liver, echinococcic cyst, gumma, or cyst of some neighboring organ.

The operative results have been satisfactory and the procedure should be as radical as is consistently safe. If enucleation can be done without severe hæmorrhage, this is the best method. If there are very firm attachments and other contra-indications to enucleation, it is best to suture the cyst wall to the parietal peritoneum and drain. Simple puncture is to be condemned. In the case reported, Norris evacuated a cyst the size of an orange, containing 200 cc. of clear fluid, sutured the cyst wall to the parietal peritoneum, drained the cavity and closed the abdomen in the usual way. Convalescence was normal and the drainage tract closed in four weeks.

HARVEY B. MATTHEWS.

Khautz: Cholelithiasis and Cholecystitis During Childhood and Its Treatment (Cholelithiasis und Cholecystitis im Kindesalter und ihre Behandlung). *Zentralbl. f. d. Grenzgeb. d. Med. u. Chir.*, 1913, xvi, 545.

By Zentralbl. f. d. ges. Chir. u. i. Grenzgeb.

The occurrence of gall-stones during childhood is extremely rare. The author was able to collect only fifteen cases. Five of these are autopsy findings and only one clinical observation in the new-born and nurslings. There were 5 cases between 5 and 10 years and 4 between 13 and 17 years old. The stones are described as polyhedral or ovoid cholesterol masses. Those in infants weighed up to 2 g. Those in older children were the size of a pea and over.

It cannot be stated whether the female sex also is predisposed during childhood; sex is not mentioned in most cases. The four cases over 13 years were all girls. The clinical phenomena are practically the same as in the adult. The diagnosis in the absence of icterus and enlargement of the gall-bladder is difficult on account of the rarity of the disease. It is confirmed only by finding the stones in the fæces as was possible in several cases. The treatment is based on the same principles as in the adult. Pure cholecystitis without stone is still much rarer. Case reports and literature are appended.

UNTER ECKER.

Bachy: Cholecystectomy in Cholelithiasis; Indications and Results (De la cholécystectomie dans le lithiase vésiculaire; indications et résultats). *Thèse de doct., Par., 1913.* By Journal de Chirurgie.

The author, basing his conclusions on 80 cases of Lejars, Gosset and Desmarest, believes cholecystectomy the only sure cure for cholelithiasis. Medical treatment is unsatisfactory as it is apt to be followed by more severe attacks, occlusion of the bile passages, intestinal or pyloric obstruction, peritonitis, biliary cirrhosis or cancerous degeneration.

Removal of the gall-bladder is made justifiable in the first place by the conditions of the paravesicular organs; acute or subacute cholecystitis with pus abscess and chronic sclerosis hydrops of the gall-bladder are all indications. No functional disturbance follows its removal. After cholecystotomies recurrences are frequent and further operation is made difficult by the adhesions formed about the gall-bladder. In acute, acute suppurative and chronic cholecystitis and in hydrops of the bladder, simple cholecystectomy gives excellent results. When the gall-bladder trouble is complicated by adhesions to the intestinal tract or dilatation of the bladder giving symptoms of obstruction, it may be necessary to do a gastro-enterostomy as well as a cholecystectomy. When there is a chronic pancreatitis, which is very hard to differentiate from gall-bladder disease alone, drainage of the common duct may be necessary in addition to removal of the bladder, but four such cases have cleared up without drainage.

Bachy advises ether anæsthesia after injection of pantopon, Sprengel's incision, cholecystectomy according to the Gosset and Desmarest method and always drainage by gauze from the cut end of the cystic duct. One cholecystectomy was done for acute cholecystitis; 46 for chronic cholelithiasis; 7 for cholecystitis with pericholecystitis; one for recurrence after cholecystostomy; 4 for fistulæ; 8 combined with appendectomy or gastro-enterostomy for cholecystitis with digestive troubles; 6 for hydrops of the gall-bladder with stone in the cystic duct; and 4 for cholecysto-pancreatitis.

The mortality was 1.25 per cent. One patient died after seven months of generalized carcinoma, primarily in the gall-bladder; another died after two years of sarcoma of the liver. There were three passing recurrences. The four cases of pancreatitis were cured.

PIERRE MOCQUOT.

Jacob: Suprapubic Fistula after Post-Typhoid Suppurative Cholecystitis; Cholecystectomy; Recovery with Persistence of the Bacilli in the Stools (Fistule sus-pubienne consécutive à une cholécystite suppurée post-typhoïdique; cholécystectomie; guérison, avec persistance de bacilles paratyphoïdes dans les fèces). *Bull. et mem. Soc. de chir. de Par., 1913, xxxix, xx, 879.* By Journal de Chirurgie.

A soldier, 21 years old, six weeks after the onset of a mild typhoid fever, complained suddenly of pain in the right half of the abdomen and in the

right shoulder. A collection developed above the pubis without jaundice or high fever. On incision pus was evacuated; later gall-stones and bile came out. Finally a fistulous opening remained in the laparotomy incision, just midway between the symphysis and navel. Small calculi occasionally, and bile containing large numbers of paratyphoid bacilli continuously, escaped from it.

Cholecystectomy through a transverse incision proved very difficult owing to the exceedingly dense adhesions. The gall-bladder was found much thickened and stuffed with calculi; its ulcerated fundus communicated with the sinus by a long fistulous tract burrowed through masses of adhesions. The hepatic and common ducts were normal. Recovery was uneventful but the man remains a chronic bacillus carrier, as his fæces contain many paratyphoid bacilli.

J. DUMONT.

Stuckey: The Employment of the Omentum for Hæmostasis in Extirpation of the Gall-Bladder (Die freie Netztransplantation zur Blutstillung bei Gallenblasen-exstirpationen). *Verhandl. d. wiss. Ver. d. Ärzte d. städt. Obuchow-Krkh., St. Petersburg, 1913, xxii, 43.* By Zentralbl. f. d. ges. Chir. u. i. Grenzgeb.

During the extirpation of a gall-bladder severe hæmorrhage occurred from the liver which could not be controlled by tamponade nor by hemostats; the latter tore through the liver substance. The author decided to use omentum to cover the defect. After pressure for 1-2 minutes the transplanted piece of omentum remained adherent to the liver surface and the bleeding was controlled completely. Three days after operation death occurred from cardiac conditions.

Post-mortem examination showed that the omental covering had become adherent over the raw surface of the liver; where the serous covering of the liver was intact no adhesions took place. There was no blood in the peritoneal cavity. On cross section it was plainly seen that the omentum had become firmly adherent to the liver substance. This observation was confirmed by microscopical sections. Only here and there were small hæmorrhages found between the omentum and the liver substance. The adjoining liver substance was markedly hyperæmic. The omental capillaries were congested.

The author compares this method with that of Clairmont and Negri, who transplanted peritoneal flaps. He points out that omental transplantation has several advantages. There is always plenty of material. It can be obtained easily with slight traumatism. It forms adhesions more readily than other tissues. The hemostatic effect is more marked.

VON SCHILLING.

Jordan: Inhibitive Action of Bile on Bacillus Coli. *J. Infect. Dis., 1913, xii, No. 3.*

By Surg., Gynec. & Obst.

To ascertain the inhibitive action of bile upon *B. coli*, pure cultures were plated in parallel series

upon plain agar and bile agar. A colony count after 48 hours incubation showed marked inhibition by bile, both of strains of *B. coli* freshly isolated from human faeces and of those long cultivated on agar or kept for a year in water suspension. Several of the freshly isolated strains were inhibited to a somewhat greater degree than other strains kept in water suspension or cultivated on nutrient agar for many generations. These results do not support the assumption that the cells of *B. coli* inhibited by bile are those which have become "attenuated" by a long sojourn in water and are thus negligible in determining recent contamination. To investigate further this "attenuation" 100 colonies of *B. coli* fished from pure culture on plain agar plates and the same number from bile agar plates were tested for vigor in milk coagulation and maximum indol production. The cells of *B. coli* grown on bile agar showed no greater physiological activity than those grown on plain agar.

Samples of water and fresh sewage were tested with lactose broth and lactose bile in parallel series. In a water series of forty 5-cc. samples each, *B. coli* was isolated from 42 per cent of the lactose broth and from 30 per cent of the lactose bile tubes. In a second series of one hundred and fifty 1-cc. samples each, *B. coli* was isolated from 31 per cent of the lactose broth and from 22 per cent of the lactose bile tubes. In a sewage series of 70 samples each, properly diluted, *B. coli* was isolated from 50 per cent of the lactose broth and from 23 per cent of the lactose bile tubes. It thus appears that bile inhibits from one third to one half of the viable cells of *B. coli*.

Lange: A Case of Free Transplantation of the Omentum in a Stab Wound of the Spleen

(Ein Fall von freier Netztransplantation bei Stichverletzung der Milz). *Verhandl. d. wiss. Ver. d. Ärzte d. städt. Obuchow-Krkh.*, St. Petersburg, 1913, xxii, 31. By Zentralbl. f. d. ges. Chir. u. i. Grenzgeb.

The patient had a stab wound in the posterior axillary line at the level of the 9th rib. Severe anæmia and marked rigidity of the abdominal wall was present. A resection of the 9th and 10th ribs was performed. The wound in the diaphragm was enlarged. A wound of the spleen bleeding severely was found. The wound of the spleen was tamponed with a free end of the omentum; hæmorrhage ceased immediately. Isolation of the pleura according to Frey and tamponade completed the operation. Recovery resulted.

O. VON SCHILLING.

Michelson: Modern Surgery of the Spleen (Die Ergebnisse der modernen Milzchirurgie). *Ergebn. d. Chir. u. Orthop.*, 1913, vi, 480.

By Zentralbl. f. d. ges. Chir. u. i. Grenzgeb.

Michelson discusses the effect of splenectomy upon the organism. Numerous cases have proven that removal of the spleen does not result in any injury to the body. A hyperleucocytosis following splenectomy is specific and may last for years

under certain conditions. The biologic characteristics of the blood are changed temporarily; the antitryptic and bactericidal power of the serum is decreased at first, but soon returns to normal. Other phenomena following splenectomy are enlargement of the peripheral lymph glands, hyperplasia of the red bone marrow with pains in the long bones and an enlargement of the thyroid gland. These, however, are not constant. Several observations lead to the conclusion that under certain conditions small additional spleens may hypertrophy and take up the function of the removed organ. Injury of the spleen is a very frequent indication for surgical procedure. Diseased conditions of the spleen predispose to lacerations. During acute infectious diseases lesser traumas such as severe sneezing, coughing, and vomiting may cause fatal ruptures; the same is true of malaria. Of the subcutaneous injuries the following are differentiated: contusions of the spleen without laceration of the capsule. These demand intervention only in case the capsule ruptures secondarily or in case a hematoma suppurates or a blood cyst is formed. 2. The definite ruptures including capsule are usually transverse tears and multiple in 50 per cent of the cases. Laceration of the left kidney frequently accompanies the injury and may render the diagnosis extremely difficult. The clinical picture may be divided into three stages: (1) symptoms of shock; (2) stage of improvement (latency) usually of short duration but occasionally lasting for several days; (3) stage of terminal internal hæmorrhage. The cessation of the primary hæmorrhage occurs usually during the initial shock. In several cases the omentum entered the tear and aided. The diagnosis of the subcutaneous injury of the spleen can as a rule be made with a certain degree of probability. The operation of choice is splenectomy; only in markedly adherent large splenic tumors tamponade should suffice. Suture of the spleen is not advisable as several tears may be overlooked. Bullet wounds, stab wounds, and other open injuries of the spleen are usually accompanied by injury of other organs (lungs, pleura, diaphragm, stomach, bowel). Isolated injury of the normal spleen can occur only when the diaphragm during the moment of injury is fixed in deep inspiration.

The diagnosis is extremely difficult and the demand that in all perforating injuries of the lower left thoracic wall and exploratory thoracotomy should be performed is therefore entirely justified. In bullet wounds splenectomy is probably always indicated; in stab wounds, however, suture can be performed in many cases.

Abscess of the spleen may occur either because of suppuration of a splenic hæmatoma or in the course of infectious diseases and is induced either by trauma or by an embolic infarct. These abscesses are characterized by their tendency to sequestrum formation. The early symptoms are not characteristic and consist of fever and chills. Pains in the region of the spleen radiating to the shoulder occur only after the abscess reaches the capsule. If the

seat of the abscess is in the upper part, the diagnosis is difficult as early involvement of the left pleura takes place. If the abscess is developed in the lower pole, a palpable splenic tumor soon appears. Fluctuation rarely occurs, likewise respiratory rubs, as the diaphragm is more or less fixed reflexly, but if they do occur are of deciding significance. Leucocytosis although frequently present is of value only in typhoid abscess. Puncture of the spleen is not without danger and should be performed only on the operating table where operative procedures may follow immediately. The prognosis of the operation is good if performed early.

Of the cysts, blood cysts are the most common, being however, not true cysts. They are always single. In contradistinction to these are the multiple serous and lymph cysts. Objective signs: splenic tumor with irregular nodular surface, fluctuation rare, rubs are frequently heard due to perisplenic adhesions. No diagnostic blood changes are present. The prognosis in general is favorable except in suppuration and ruptures. The best surgical procedure is resection; in very large cysts with not too firm adhesions splenectomy must be considered; in very large cysts with firm adhesions, incision and drainage must suffice. Echinococcus cysts of the spleen are unilocular. They develop most commonly in the center of the organ, pushing both poles away from the center. This gives the organ a characteristic long-drawn-out shape. If hooklets are present, the diagnosis is clear. Exploratory puncture is advised against on account of the danger. Operative treatment consists in opening the cyst widely, extracting the mother membrane, and employing wide tamponade. To shorten convalescence it is advisable to bring the edges of the cavity together with sutures thus eliminating it.

Of the malignant tumors of the spleen sarcoma alone demands surgical interest. The diagnosis is made in the presence of rapidly developing, hard, nodular tumors in the absence of blood changes, fever, fluctuation, and malaria, but accompanied by severe pains due to tension of the capsule and traction on the ligaments. Recurring malaria is the most frequent cause of tumor-like hyperplasia of the spleen. The malarial spleen as a rule assumes enormous dimensions; its consistency is firm and the cut surface has the appearance of raw meat. Around it firm, but highly vascular adhesions are formed, especially at the lower pole. Pressure symptoms as a rule are mild; but the dystopic spleen by traction on its ligaments causes severe pain. The diagnosis as a rule is not difficult when the history and the characteristic form of the tumor are considered. Extirpation should be undertaken only in the presence of severe disturbances and in which the upper pole lies below or only a little below the edge of the costal arch. Partial ligature of the vessels of the pedicle is technically as difficult and has not proven practical. Splenopexy likewise has not found many adherents. The occurrence of an isolated tuberculous splenomegaly has been proven to exist but is

relatively rare. That occurring in the miliary form of tuberculosis develops slowly and may cause quite an enlargement of the organ which at times is nodular. The general condition is not materially affected in contradistinction to the splenic pseudo-leukemia in which the general condition with similar enlargement is severely affected. The diagnosis has rarely been made. The increase of the red blood cells (hyperglobulia) described by Rosengart is not pathognomonic. The treatment should be splenectomy performed as early as possible; it may be impossible in the presence of extensive adhesions in advanced cases. It is advisable to suture the spleen to the abdominal wound to establish drainage.

A wandering spleen usually occurs in the presence of diseased conditions and enlargements and especially during pregnancy. Sudden torsion of the pedicle causes stormy symptoms similar to torsions of ovarian cyst pedicles. In the presence of severe symptoms surgical treatment is indicated in a wandering spleen; splenectomy for markedly diseased spleen except in leukemia and splenopexy according to Bardenheuer for a small wandering spleen. Surgical intervention is contraindicated in leukemia, anemia splenica infantum, and in the splenomegaly of amyloid disease. Of the idiopathic splenomegalies Banta's disease alone interests the surgeon.

NEUPERT.

Giffin: Clinical Observations Concerning Twenty-Seven Cases of Splenectomy. *Am. J. M. Sc.*, 1913, cxlv, 781.

By Surg., Gynec. & Obst.

The histologic examination of the spleen in cases of splenic anemia reveals no constant histological picture, and the author here reports the clinical findings in the twenty-seven cases in which splenectomy has been performed in the Mayo Clinic. For convenience these are divided into three groups: (1) those which conform closely to the clinical syndrome of splenic anemia, eighteen in number; (2) cases presenting clinical features which suggest that the splenomegaly was a part of a more or less widespread infection, and secondary rather than primary; (3) miscellaneous cases. In the study of these cases the author shows twenty-seven cuts outlining the splenic tumor and tabulates the post-operative results, giving the pathology, blood counts and all clinical data concerning them.

The author concludes that a proper grouping of cases showing marked splenic enlargement with an anemia of the secondary type is at present quite impossible, and that the clinical features form the best basis for a tentative classification. It assists especially in recognizing clean-cut and uncomplicated cases of splenic anemia. The review indicates a possible relationship between gall-bladder disease and splenomegaly and indicates more clearly in uncomplicated cases of splenic anemia that a large percentage of cases return to excellent health after splenectomy, but in cases complicated by other diseases of an infectious nature the value of splenectomy is questionable.

H. A. POTTS.

SURGERY OF THE EXTREMITIES

DISEASES OF BONES, JOINTS, MUSCLES, ETC.
GENERAL CONDITIONS COMMONLY
FOUND IN THE EXTREMITIES

Cluzet and Dubreuil: Action of the X-Ray on the Development of Callus. Comparative Study of Radiographic and Microscopic Aspects of Callus (Action des rayons X sur le développement du cal. Etude comparative des images radiographiques et microscopiques du cal). *J. de physiol. et de pathol. gen.*, 1913, xv, 367.
By Journal de Chirurgie.

In the author's experiments fractures were produced in the legs of dogs and then immobilized in plaster. Some were treated with Röntgen rays and the dogs killed after a variable time in order to determine the influence of the rays upon the formation of callus. Others were radiographed but not subjected to long exposure and were used to determine the histologic significance of the radiographic appearance of new-formed callus. He concludes:

Cartilaginous callus uniting a fracture is not recognizable by shadows.

The union may appear firm upon clinical examination as a result of fibrous or cartilaginous callus, and yet the radiograph may resemble that of a recent fracture.

In a dog not exposed to treatment with the rays, the bony callus makes its appearance between the eleventh and seventeenth day. In one treated by long exposure to the X-rays on different aspects of the fracture, the bony callus is delayed until the forty-first day.

If only one aspect of the fractured surface has been exposed to the rays the callus appears first on the opposite side.

These effects of the rays are the same whether the exposures are made before or after the fracture, but the formation of the callus is only delayed; it finally follows its normal course.

PIERRE CRUET.

Machard: The Use of Tuberculin in Osseous Tuberculosis in Children (De l'emploi de la tuberculine dans la tuberculose osseuse chez les enfants). *Rev. méd. de la Suisse romande*, 1913, xxxii, 333.

By Journal de Chirurgie.

Machard has experimented with TBk (Beranek's tuberculin) in twenty-one cases of osteo-arthritis tuberculosis in children from four to fourteen years of age. One fungus osteo-arthritis of the knee, ten coxalgias and six spondylitis cases were treated by focal injections and four by hypodermics. Five cases treated focally resulted satisfactorily, four had doubtful results and seven, negative. In the fungus osteo-arthritis of the knee, the condition was aggravated. The successful cases would undoubtedly have cleared up as rapidly under the usual treatment.

In those treated locally the amount of local reaction and the changes in temperature varied greatly with the same dose, showing no relation to the amount or quality of tuberculin used. In fact, the

temperature changes in patients who were not getting tuberculin and in the periods of rest of those who did get injections were just as great as in those who were receiving regular treatment. Machard is of the opinion that tuberculin treatment of osteal and articular tuberculosis in children can not replace the other conservative treatment and in fact is dangerous in certain cases.

Sahli advises seeking a negligible local reaction, whereas Coulon advises a strong local and general reaction. It seemed difficult to find the amount of TBk necessary to produce a negligible local reaction.

VALLETTE stated, in discussion that Machard's technique differs from that used by Coulon. Generally speaking, Machard uses weaker doses at four-day intervals, whereas Coulon makes his injections every eight days. Further, Machard treated cases of vertebral tuberculosis in which the site was hard to bring in contact with the TBk. In the fungus osteo-arthritis case favorable results might have been obtained by subcutaneous injections. Coulon has had good results in adults as well as in children. Vallette believes that Coulon's positive cases are very encouraging, and that more work should be done along this line.

J. DUMONT.

Vulpis: Treatment of Surgical Tuberculosis by Means of Light Rays (Über die Lichtbehandlung der chirurgischen Tuberkulose). *München. med. Wchschr.*, 1913, lx, 1079.

By Zentralbl. f. d. ges. Chir. u. i. Grenzgeb.

The author discusses the physiological influence of light, with special reference to its remote effects. He reviews the technique of heliotherapy, used by Rollier for its general systemic effect, and by Bernhard for its local effect, on the diseased area in cases of surgical tuberculosis. Clinical experience at the Rappenan sanatorium has convinced the author that heliotherapy can be as successfully applied in the lowlands as in high altitudes if one takes advantage of the artificial light rays. The author employs the electric arc light as well as the quicksilver vapor light and the quartzlamp.

He believes that light therapy is destined to take an important place in the treatment of surgical tuberculosis. "We can state positively that light therapy in its present form in the lowlands can compete with heliotherapy of the highlands. This has been made possible by the ease with which natural and artificial light can be combined. When the two methods are compared it cannot be disputed that artificial light has certain advantages. It is always at our disposal and not dependent upon weather conditions. The amount and intensity of the light can be regulated, which is not true of the ever varying sunlight with its uncertain ultraviolet constituents. The quartzlamp furnishes a richness in ultraviolet rays which surpasses even that of natural sunlight of the highlands."

BRANDES.

Müller: A Case of Acute Bone Atrophy (Über einen Fall von akuter Knochenatrophie). *Deutsche militär. Ztschr.*, Berl., 1913, xlii, 387.

By Zentralbl. f. d. ges. Chir. u. i. Grenzgeb.

Müller treated a case of acute bone atrophy for many months and states that it is desirable in such a condition to have X-ray examinations taken as early as possible. The diseases with which this may become confused are chronic articular rheumatism, neuritis, traumatic joint conditions, phlegmons of the soft parts, herpes zoster, etc. The typical findings upon X-ray examination are the involvement of the base and head of the bones, not of the diaphysis, as is observed in chronic atrophy due to inactivity or senile atrophy.

The author believes with Sudeck and Kienböck that acute bone atrophy is due to tropho-neurotic reflex disturbances and recommends, if the diagnosis is correct, energetic passive motion instead of the usual treatment of rest and wrapping the limb in cotton. In his own case, the author obtained also a good functional result within a short time. In conclusion, he points to the fact that in spite of the good functional result obtained, the bone atrophy persisted unchanged. According to his point of view, the affection consists not merely in a rare action of the bone salts, due to the prolonged atrophy, but in a solution of the entire bony framework. KNOKE.

Molineux: The Multiple Brown Tumors Found in Osteomalacia (Über die multiplen braunen Tumoren bei Osteomalacie). *Arch. f. klin. Chir.*, 1913, ci, 333. By Zentralbl. f. d. ges. Chir. u. i. Grenzgeb.

The author reports in detail three cases which he classifies as osteitis fibrosa atrophica on the basis of pathological-histological studies in contradistinction to the osteitis fibrosa hypertrophica in which an increase of bony substance takes place. He emphasizes the fact that even in view of the appearance of the brown giant-celled sarcoma-like tumors there is no essential difference between these two forms of the disease. The different forms of bony malformations he attributes to loss of balance between the bone-forming cells and the bone-destroying cells, caused either by an irritation or a destruction. As the cause of the disease is still unknown it is of importance to know that the author in three cases found a definite hyperplasia of the parathyroids. The findings reported first by Erdheim are therefore confirmed. In the interpretation of the brown tumors the author's views coincide with those of Lubarsch and Rehman. He considers the epulis-like tumors not as definite new growths but as hyperplasias incident to the irritative and destructive processes occurring in the bones. STAMMLER.

Domingo: Cystic Tumor of the Head of the Femur (Tumeur kystique de la tête du fémur). *Rev. de l. Hosp.*, Montevideo, 1913, vi, 3.

By Journal de Chirurgie.

The patient some years before coming under observation had violently twisted his left lower limb,

injuring the hip. He was confined to bed for one month and was not able to walk for five months. Four years ago the patient fell from a horse upon the left hip. Following this accident he experienced pains in the inguinal region. He began to limp and one year ago noticed a swelling at the outer part of Scarpa's triangle which steadily increased.

Examination showed a swelling in the above named region and atrophy of the limb. Movements were painful. Immediately inferior to Poupart's ligament there was a hard irregular mass of about 8 cm. in diameter; also several small glands. The great trochanter was increased in size. X-ray showed a tumor the size of an orange, surrounding the head of the femur, the anatomical neck and upper part of great trochanter.

Operation. Antero-external incision. The tumor was opened and bloody fluid escaped; the cavity was lined with loose soft tissue and in the wall were smaller cavities giving the cyst a sponge-like appearance. The cavity was packed, and following the operation, it contracted and healed. Histological examination of the bony fragments revealed a cystic enchondroma. The author entered into a full consideration of cysts of the long bone. SALVA MERCADÉ.

Brooke: The Treatment of Gonorrhœal Arthritis. *Hahnemann. Month.*, 1913, xlviii, 417.

By Surg., Gynec. & Obst.

Results in these cases are not good. The author had all degrees of limitation of motion and believes from the literature that such is the usual result in the severe cases. There is no such thing as an idiopathic arthritis, but a primary focus always exists with a definite period of metastasis for each organism — streptococcus, 24–28 hours; grippe, 9 days; gonorrhœa 19 to 22 days.

Gonorrhœal arthritis gives sudden onset involving several joints of which all clear up but one. Thus it differs from tuberculosis, in which the onset is slow and never under three weeks after injury. The knee is the most frequent site of gonorrhœal arthritis. Destruction is due to the accumulation and pressure of products of infection in the capsule.

Brooke advises aspiration and injection of 5 to 10 cc. of 2 per cent formalin glycerine at intervals of from a day to a week. He secures extension by Buck's adhesive dressing with weight enough to separate the joint surfaces and relieve pain; opens and clears out the joint, if aspiration is impossible on account of thick fluid; considers vaccines next in importance to surgical measures; and uses Neisser mixed vaccine from 50 to 500 million at a dose. Bier's hyperæmia is of use in subacute stages. C. E. WELLS.

Edberg: Purulent Arthritis in Sucklings and Its Importance in Future Deformities (Om purulenta spädbarnsartriter och deras betydelse för framtida deformiteter). *Hygeia*, 1913, lxxv, 203.

By Zentralbl. f. d. ges. Chir. u. i. Grenzgeb.

The author reports four cases of purulent coxitis, one case of omarthrititis, one case of simultaneous

omarthrititis and gonitis, and one case of bilateral gonitis. The bacteriological examination verified the presence of pneumococci in a three weeks' old coxitis; staphylococci (pyog. aur.) in three cases; viz., in a five weeks' old coxitis, a ten days' old omarthrititis and a five weeks' old omarthrititis and gonitis; and streptococci in a two months' old bilateral gonitis. Two cases of coxitis (one three weeks old and one 1½ years old) were not examined bacteriologically, though the author is of the opinion, for valid reasons, that both were due to septic infections. The author's views in this connection are in direct opposition to those of Rovsing, who in 1896 asserted that in sucklings many cases of joint inflammations that are described as septic are in reality of a tuberculous nature. The author corroborates the prevailing conception as to the significance of acute enteric catarrh in bone and joint inflammations. He is of the opinion that the "catarrhal synovitis" of the old Volkmann school is the usual pathological anatomical form, notwithstanding the fact that osteal involvement is observed occasionally. The author bases his opinion upon the rapid healing frequently following slight arthrotomies. None of the author's cases ended fatally; the suppuration terminated after a very small incision. Fortunately, the author was able to observe the cases described for several years. None of the coxitis cases showed a luxation at the time of the first operation; in two cases of coxitis complete luxation developed; in a third, a subluxation; in a fourth, coxa vara. According to the author, the luxations developed less frequently in the acute stage of the septic coxitis. Invariably these coxitis developed early para-articular abscesses; the exudate of the joint perforated early and the capsules' expansion properties were diminished. It is not easy to assume that the luxation depends primarily upon the distension, in case the former does not occur before the capsule is perforated. In sucklings there are no septic destructive luxations observed, like those that occur in osteomyelitic coxitis in a somewhat advanced age. The most remarkable observations brought to light by radiographic examinations are the extensive atrophy and deformity of the entire intra-articular part of the extremity. There is a marked incongruity between the head and the extremities in this respect, which is noticed with increasing force and frequency as the extremities are approached. This condition is influenced by motion, muscular forms, and the burden imposed — all of which tend to induce luxations.

The author points to the possibility of a radiographic differential diagnosis between congenital luxations of hip-joint and those resulting from coxitis occurring during the suckling age. The author claims priority for these studies, which were first described by Drehmann.

In two cases of luxation of the hip-joint operative reposition was successful. In none of three cases of gonitis which the author could observe, was there a permanent injury following upon a purulent arthri-

tis. These cases present a favorable prognosis, presuming early and correct treatment.

In a subsequently examined case of omarthrititis, atrophy of the head of the joint and a soft crepitation were established; but no tendency toward an habitual luxation was noted.

GIERTZ.

Greiffenhagen: The Mobilization of an Ankylosed Elbow-Joint by Means of Periosteal Transplantation (Über Mobilisierung des ankylotischen Elbogengelenks durch freie Periosttransplantation). *St. Petersb. med. Ztschr.*, 1913, xxxviii, 93.

By Zentralbl. f. d. ges. Chir. u. i. Grenzgeb.

For the mobilization of an ankylosed elbow-joint, Greiffenhagen advises the interposition of periosteal flaps which may be taken from the tibia. In the removal of the periosteum it is advisable to include cortical fibers. The flaps are laid and fixed upon the freshened bone surface with the osteoplastic layer upon the sawed surface. The outer wound is closed almost completely, a small drainage tube being inserted in one angle. The arm is kept quiet. After a few weeks passive motion is begun. The defect in the tibial periosteum is closed immediately and no disturbance occurs. The author described three cases.

HOHMEIER.

Marchal: Traumatic Lesions of the Meniscus of the Knee (Lésions traumatiques des ménisques du genou). *Bull. Ass. med. belge d. accidents du travail*, 1913, ix, 241.

By Journal de Chirurgie.

Marchal reports eight cases of traumatism to the knee resulting in injury to the internal meniscus. From these cases and those in the literature he has come to the following conclusions:

1. Injury to the meniscus is produced by direct or indirect traumatism caused generally by sudden torsion of the knee.
2. The internal meniscus is usually affected.
3. The symptomatology is varied: (a) Localized pain over the meniscus; (b) hydro-arthritis, slight or extensive; (c) fixation of the joint as by a foreign body; (d) limitation of motion, especially extension; (e) abnormal mobility of the knee.

Extirpation gives better results than suturing of the meniscus. The operation is simple but strict asepsis must be employed. The author advises early exploration in all cases of chronic hydro-arthritis so that atrophy of the triceps may be prevented.

J. DUMONT.

Bartow and Plummer: Further Observations on the Use of Intra-articular Silk Ligaments in the Paralytic Joints of Poliomyelitis. *Am. J. Orth. Surg.*, 1913, x, 449.

By Surg., Gynec. & Obst.

The authors have described in a previous paper a technique designed to give better control of the more or less flail joints following poliomyelitis. In brief, the procedure is to so introduce paraffined silk into the joint as to hold the parts in correct weight-bearing posture, and at the same time allow of a

certain amount of movement. The silk is expected to act as a mechanical agent in holding the correct posture for a time, but, eventually, to become invested with a strong covering of fibrous scar tissue, which will act as an interarticular check ligament, in effect somewhat like the normal crucial ligaments of the knee.

The operation as described is as follows: For example, a paralytic valgus with drop foot; a small incision over the inner malleolus down to the bone. At this point a specially designed curved drill, diamond pointed and with an eye in the point, is entered into the bone and forced downward and forward, traversing malleolus, astragalus, scaphoid and inner cuneiform. At the point of emergence, a small incision is made and one or more strands of the silk led back through the tunnel in the bones. A second insertion of the drill at the upper point is carried to the lower, not through the bone, but through the integument around the joints, and the other end of the silk strand is led back to the first point, forming the loop. This is pulled up tight and tied, pulling the foot into a slight varus and dorsoflexion. A plaster splint retains the position for from 12 to 20 weeks, and a modified shoe is then applied and walking begun.

This procedure may be varied to include both sides of the foot for drop, into the os calcis for calcaneus, or through the condyles and the heads of tibia for flail-knee; also through the anterior superior spine of the ileum and greater trochanter for paralysis of internal rotators; also through the acromion and head of humerus for paralysis of the shoulder and subsequent luxation of the humeral head.

The authors state that, all told, over 100 joints have been so treated, and in almost all of these there has been marked improvement in function and position.

Earlier cases relapsed, but a longer plaster fixation, allowing longer time for the scar envelope of the silk to form, corrected this detail.

There have been no infections, and in only three cases was it necessary to remove the silk, and that only after a period of from three to six months. In all these latter cases there was no sign of infection. The silk was partially disintegrated, and after removal the corrected posture was well maintained by the interarticular scar.

The authors wish to call attention to the necessity of absolute asepsis in the handling of the silk; also all secondary deformity-producing factors must be recognized and properly dealt with. Contractures, strong opposing muscles, etc., must be eliminated. It frequently happens that a knock-knee complicates a flail valgus foot, and it is essential to correct the knee posture as well as the foot. Other such combinations will suggest themselves.

The authors state that they feel that this measure will find a very useful field in the early surgical treatment of these lesions, as there has been no destruction of joints, and any late returning muscle power will not be interfered with. It also obviates

a long and protracted period of apparatus treatment, and furthers the use of developmental exercises.

The authors do not advocate this method as the only treatment for flail joints, but in properly selected cases have found it the best method and very useful in combination with some of the other operative procedures.

Tourneux: Sarcomas of the Tendon Sheaths (Les sarcomes des gaines tendineuses). *Rev. de chir.*, 1913, xlviii, 817. By Journal de Chirurgie.

The author reviews 93 cases of sarcoma of the tendon sheaths; in 66 the tendon sheaths of the upper limbs were involved and in 27 those of the lower. The tendons of the hand, especially the flexors, were affected most commonly. Trauma is often the original cause and it sometimes starts a rapid growth in already existing tumors. The tumors are lobulated, reddish yellow in color and very vascular. The connective tissue forms are hard, the cellular forms soft. The tendon is last invaded, but the muscle and cellular tissue offer but slight resistance. Degeneration is rare and visceral metastases uncommon. There are round, epithelioid and giant cell sarcomas; myo-, fibro- and alveolar sarcomas, these by some authors being classed as endotheliomas. The giant cell form is not common.

The beginning is slow and insidious; rapid growth indicates malignancy. The tumor is at first interlobular, hard or elastic and not reducible. The tendons and skin are involved late in the process. Pain is a late and not marked symptom. When the tumor becomes malignant it grows rapidly, invading neighboring tissues and becoming generalized by the blood-stream. Generalization occurred in only six of the cases cited. Recurrence is quite frequent (21 cases) and even the giant cell sarcomas recur. They must be distinguished from arthrosynovial cysts, exostoses and osteosarcomas. Muscular sarcomas are differently located. The treatment should be surgical and radical if the tissues are infiltrated (amputation or disarticulation).

In fourteen cases of round cell sarcoma there were eight recurrences usually with generalization and in sixteen cases of the epithelioid form, six recurrences. These recurrences should be treated by secondary amputation. J. OKINCZYC.

Spieß: The Giant-Celled Sarcomas Originating in the Tendon-Sheaths and Aponeuroses (Zur Lehre der von Sehnnenscheiden und Aponeurosen ausgehenden Riesenzellensarkome). *Frankf. Zschr. f. Pathol.*, 1913, xiii, 1.

By Zentralbl. f. d. ges. Chir. u. i. Grenzgeb.

Spieß studied forty-eight cases reported in the literature and four of his own observation in regard to the pathologic-anatomic characteristic of these tumors (for the details the original work must be consulted) and on the strength of his studies came to the conclusion that they are a variety *sui generis*. They arise principally from the tendon sheaths of the fingers and from the palmar aponeurosis.

Etiologically no definite cause has been found, and chronic granulation processes can safely be excluded. The development takes years, yet the tumors never become larger than an egg. The tumor is definitely benign; they should not recur after thorough removal. Their pathologic-anatomic characteristics are as follows: 1. They contain a fairly large amount of hemosiderin. 2. There are many multinuclear giant cells present. 3. The so-called xanthoma cells are found. 4. The structure is ragged. The tumor is sharply limited by a connective tissue capsule. It resembles epulis considerably, especially if many giant cells are found. Spiess suggests the name "hemosiderin containing sarcoma gigantocellular xanthomatodes of the tendon sheaths and aponeuroses." KNOKE.

Fleissig: The Granulomata of Tendon-Sheaths Heretofore Defined as Giant Cell Sarcomata: Myelomata (Über die bisher als Riesenzellensarkome—Myelome—bezeichneten Granulationsgeschwülste der Sehnenscheiden). *Deutsche Ztschr. f. Chir.*, 1913, cxvii, 239. By *Zentralbl. f. d. ges. Chir. u. i. Grenzgeb.*

Fleissig had occasion to observe two cases of tendon-sheath tumors during the past two years. The large majority of such tumors have previously been considered giant-celled sarcomas (myelomas). New detailed investigations have shown, however, that these tumors lack the principal diagnostic points of neoplasms, such as polymorphism, polychromasia, destructive invasion of surrounding tissues and mitosis. For the recognition of such affections the macroscopic appearance, such as their small size, their ragged structure and their yellowish marbled appearance, is important. In support of his view Fleissig cites several illustrative cases from the literature. These granulomata take their origin more frequently from the tendon sheaths of the fingers, especially from the flexor tendons, more rarely from the tendon sheaths around the malleoli and the radiocarpal joints. They do not recur. The conclusion may be drawn that no mutilating operations are necessary, but that the careful extirpation of the diseased tissue suffices. KNOKE.

FRACTURES AND DISLOCATIONS

Dejouanny: Fracture and Dislocation of the Internal Meniscus of the Knee; Excision; Cure (Fracture et luxation du ménisque interne du genou; méniscectomie; guérison). *Bull. et mem. Soc. de chir. de Par.*, 1913, xxxix, 484. By *Journal de Chirurgie.*

This communication by Dejouanny was presented by Lejars. The latter pointed out the rarity of operation for lesions of the meniscus in France which is in marked contrast to its frequency in England.

The case operated upon by Dejouanny was that of a cavalryman who was thrown from a horse and whose leg was forcibly flexed and rotated outward.

He was soon able to go about his work but frequently slight movements caused the limb to become locked in semiflexion and the knee joint full of fluid.

A diagnosis of a traumatic lesion of the internal meniscus was made. This meniscus was easily removed and found to consist of two fragments of fibro-cartilage 26 mm. and 25 mm. in length; the posterior fragment being easily folded onto the anterior. The anterior fragment was attached to the tibia; the posterior was free in the joint cavity. A perfect recovery was obtained.

Lejar mentioned several cases in which he had made a diagnosis of trauma to the internal meniscus and reported one of these on which he operated. Here there was merely a very movable cartilage which was removed. It was still too soon to judge regarding the result.

To make a diagnosis of this condition there should be a sudden painful fixation of the knee followed usually by a hydrarthrosis, and a painful point and ridge in the region of the meniscus when the limb is in extension but disappearing when it is flexed. A total meniscectomy is the only manner in which to obtain a permanent cure even if it is only an abnormally movable cartilage.

Demoulin, Michon, Arrou, Kirmisson, Tuffier, Quénu, Maclaure and Lejars then reported series of cases of injury to the internal meniscus and discussed the etiology, diagnosis and treatment of the condition. J. DUMONT.

Gelinsky: The Treatment of Fracture of the Calcaneum and Injuries to the Middle Bones of the Foot With Extension (Die Extensionbehandlung bei Calcaneumfraktur und den Verletzungen der Mittelfussknochen). *Zentralbl. f. Chir.*, 1913, xl, 809. By *Zentralbl. f. d. ges. Chir. u. i. Grenzgeb.*

In oblique fractures of the os calcis in which the arch has sunken, as in flat foot, the author advises tendo achillis tenotomy with extension of the foot by means of a thin board fitted to it. This is attached to the anterior part of the foot with adhesive plaster and to the heel by a strong silver wire which by means of a thick, round, straight needle is pulled through the angle between the origin of the tendo achillis and the tubercle of the os calcis. In the hollow of the arch a rubber sponge is placed. Extension is applied by means of a cord applied to the middle of the board. After two weeks the sponge is removed and the hollow is filled up with plaster of Paris, the board is fastened to a plaster shoe and the patient is allowed to walk about. A similar method without tendo achillis tenotomy is applicable to malleolar fractures and all direct fractures of the middle part of the foot. STREISSLER.

Hardouin: Complete Backward Dislocation of the Knee; Cure by Continuous Extension (Luxation complète du genou en arrière; guérison par l'extension continue). *Bull. et mem. Soc. de chir. de Par.*, 1913, xxxix, 806. By *Journal de Chirurgie.*

Hardouin reports the case of a jockey who was thrown from his horse and suffered a complete backward dislocation of the knee. This was easily reducible, but would not remain in place. Four and

then six kgm. extension weights were applied, which kept the knee in position. After 15 days the extension was removed; after 34, the patient walked, and after 45, he left the hospital. Six weeks later he was able to ride in races.

Hardouin then made some clinical and experimental researches and found that there were two types of backward dislocations, one in which the posterior cervical ligament alone is destroyed and one in which all the ligaments are torn. In the first type the dislocation can occur only backward; in the second the head of the tibia can be carried forward and also sideways.

J. DUMONT.

SURGERY OF THE BONES, JOINTS, ETC.

Murphy: Old Ununited Fracture of Anatomic Neck of the Femur; with Suggestions for the Immediate Treatment of this Fracture. *South. M. J.*, 1913, vi, 387. By Surg., Gynec. & Obst.

The author first discusses the causes of non-union of fragments in fracture of the neck of the femur, under all forms of treatment, and concludes by saying that there are certain fractures of the neck which must result in non-union, no matter what form of treatment is employed, short of operative procedure, the reason for this being the interposition of tissue between the ends of the fragments. It is in these cases that an open operation is positively indicated. The operator follows no single plan in exposing the seat of fracture, but in certain cases uses a longitudinal incision, and in others a U-shaped incision. When the trochanter must be removed the U-shaped incision is employed and a Gigli saw is then passed beneath the muscles attached to the trochanter, and the trochanter divided. By adducting the leg and turning the foot outward the fractured end of the neck of the femur and the shaft are easily exposed. If the trochanter is not to be removed the incision should be a straight one. In this case the fascia lata is divided, and the fibers of the gluteus medius muscle are separated, giving one immediate access to the fracture of the neck of the femur.

When the interposing tissue is removed, the ends of the fragments are freshened and approximated. Two or more 8, 10, or 12-penny wire nails are driven through the neck into the head from the shaft side of the bone. The trochanter, if it has been removed, is then nailed into position with one wire nail. The soft parts are sutured, the wound closed without drainage. No cast is applied. Both legs are then placed in a travois splint so as to insure abduction of the affected leg. The author emphasizes the importance of this splint in order to maintain abduction. A number of illustrations and X-ray pictures follow, explaining the author's methods.

The plaster of Paris cast, including both hips with abduction of both legs, meets the conditions in impacted fractures, but it is very inconvenient to the patient. The so-called "railway splint" is likewise deficient. However, no splint, even with extension, abduction or lateral traction, can secure union of the

fragments when the capsule or other soft tissue lies between. The amount of traction should vary with the musculature of the individual, usually between 15 and 35 pounds. The author advises the use of the old fashioned diachylon mole-skin plaster, as rubber adhesive plaster frequently produces an eczema.

The author cautions against applying the Buck's extension so that pressure upon the external popliteal nerve may not occur where it passes around the neck of the fibula, lest footdrop result. In applying the cast a window should be cut at this point.

In from eight to sixteen weeks, in adults, bony union will take place between the fragments of the neck of the femur. In children from five to eight weeks are sufficient to produce firm bony union.

In all of this bone work strictest asepsis must necessarily be maintained. FREDERICK G. DYAS.

May: The End Results Following the Radical Operation for Knee-Joint Tuberculosis in the Adult (Über das Endresultat radikal operierter Kniegelenktuberkulosen bei Erwachsenen). *Deutsche Ztschr. f. Chir.* 1913, cxxii, 171.

By Zentralbl. f. d. ges. Chir. u. i. Grenzgeb.

Since Brandes reported the results of operated cases of knee-joint tuberculosis up to the fifteenth year, the author now renders the results in those over fifteen. Among seventy-seven cases, amputation was performed seventeen times (eight times primarily and nine times secondarily). In the three arthrectomies one excellent result was obtained in an eighteen-year-old girl after excision of the fistula, excochleation of the synovial membrane, drainage and hyperæmia. It is now ten years since the onset of the disease; her gait is perfect, her movement complete and she is able to dance. Of the forty-eight resections which did not need a secondary amputation, the author was able to examine thirty personally. The operation of choice was the curved method of resection according to Helferich. By means of eight instructive tables the author gives the clinical course, findings, duration and result and treatment.

Final results: A total of seventy-seven operations were performed on sixty-seven adult patients; twenty-three of these died, seventeen of tuberculosis. Of fifty-seven cases of resection fifty-five were followed up. Of these, thirty-three are living and cured, with firm ankylosis; only two are unable to perform their labor; nine died, but the condition at the time of death was cured; nine had to be amputated secondarily and four died with the condition not cured.

EUGEN SCHULTZE.

Göbell: The Treatment of Ischæmic Muscular Contraction by Free Muscle Transplantation (Zur Beseitigung der ischämischen Muskelcontractur durch freie Muskeltransplantation). *Deutsche Ztschr. f. Chir.*, 1913, cxxii, 318.

By Zentralbl. f. d. ges. Chir. u. i. Grenzgeb.

Following a redressment on account of a flexion contracture of the right elbow after an extensive

fracture, an ischæmic contracture involving the second, third, fourth and fifth fingers set in. In mid-position of the hand almost complete flexion of the fingers was present, which increased with dorsal flexion. Göbell attempted to perform a free transplantation of the muscles which still contained their nerve supply. At the operation the forearm fascia was cicatricially contracted and fibrous, the musculus palmaris contracted; the flexor sublimis showed marked, and the profundus, very marked, fibrous degeneration, so that the knife grated when the muscle was cut. After the flexors were severed 2 cm. above the tendinous part, the fingers relaxed and could be straightened. In the defects 5-6 cm. long the following muscle pieces were implanted: the upper end of the sartorius into the flexor profundus, that part of the external oblique belonging to the tenth intercostal nerve into the sublimis. The transplanted nerves supplying the muscles were implanted into the median nerve after stimulation to determine the presence of motor fibers. The fascial defect was supplied from the fascia lata. Under after-treatment according to Jores with faradization twice daily, improvement during the four months had progressed so far that the extended fingers could be flexed to touch the palm of the hand, and finally the entire function of the fingers returned.

The result could not be attributed to the lengthening of the muscles, as their injury was too severe, and as improvement occurred only after several months. On the other hand, the transplant could not have retained its function, as the electrical stimulation never caused an isolated contraction of the transplant. According to the experiments conducted by the author, it is highly probable that the transplant became necrotic to a large extent, and the continued elastic traction due to the contraction processes caused a marked stimulation and regeneration of the remaining muscle tissue and also probably of the transplanted tissue. The method of free muscle transplantation in such cases is superior to the resection method of Henle-von Mikulicz and to the recently published corpus resection method of Klapp.

Müller: The Operative Treatment of Lame Feet
(Beitrag zur Operation gelähmter Füße). *Zentralbl. f. Chir.*, 1913, xl, 812.

By Zentralbl. f. d. ges. Chir. u. i. Grenzgeb.

I. Operation for pes calcaneus paralyticus. In isolated paralysis of the gastrocnemius and soleus muscles, Müller uses the flexor longus hallucis on the inner side, as it is farthest posterior, is powerful and can be utilized without causing much disturbance in the great toe. On the outer side he uses the peroneus brevis and not the longus, as the latter is the antagonist of the tibialis posticus. After isolating both tendons

he carries them through two holes made in the calcaneus to the median and lateral side and draws them taut so that the foot rests in plantar flexion. He then sutures the central end of the flexor hallucis to the tendon of the peroneus brevis, and the central end of the peroneus brevis to the tendon of the flexor longus hallucis, so that he obtains a muscle with two heads. The tendo achilles is then shortened by folding it upon itself. The foot is fixed in plantar flexion for four or five weeks.

II. Arthrodesis of the talotarsal joint in paralytic feet. The disturbing shakiness in the talotarsal joint occurs either as varus or valgus position of the foot and not in the talocrural joint, which forms a broad roll. Müller stiffens the Chopart and talocalcaneal joint by adding a resection of the cartilages. He thus obtains a foot which in its posterior part is quite firm, as the talus, calcaneum, navicular and cuboid bones then form a firm bony mass, pronation and supination being excluded. The foot can develop normally.

SCHMITZ.

Vedova: Supracondyloid Osteoplastic Amputation of the Femur for Movable Artificial Legs
(Amputation fémorale supracondylienne ostéoplastique à capuchon cinématique). *Revista osp.*, 1913, iii, 337.

By Journal de Chirurgie.

In the case of the lower limb resistance to pressure is the chief quality to be sought for. The osteoplastic occlusion of the medullary canal and the active mobility of the soft parts between the bone and artificial limb are of great importance. Different methods of obtaining this resistance were studied, especially that of Gritti.

In the Gritti operation the cut surface of the bone is protected by turning back the patella and holding it in place by suturing its ligaments to the flexor tendons (Rioblanco's method). The author believes that the stump would be much more serviceable if a movable osteocutaneous flap were placed below the bone stump, being made movable by the flexors and extensors of the leg.

Instead of removing the patellar cartilage, as Gritti does, Vedova leaves the patella intact. He makes a new cartilage-covered end for the femur by transplanting cartilage-covered bone from the condyles and trochlea over the bony stump. To do this transplantation successfully, the two pieces must be cut exactly perpendicularly and the femur cut obliquely from before backward. The patella is then reflected to cover the stump as in the Gritti operation.

The author has tried this technique in only one case and has been able to follow it for only a short time. He is, however, favorably impressed by the good location of the plastic flap, the persistent mobility of the patella and the good preservation of the muscles attached to it.

AMEUILLE.

ORTHOPEDIC SURGERY

DISEASES AND DEFORMITIES OF THE SPINE

Henderson: The Operative Treatment of Tuberculosis of the Spine. *St. Paul M. J.*, 1913, xv, 277. By Surg., Gynec. & Obst.

A brief résumé is made of the conservative treatment and the principles underlying it. The author refers to the importance of securing a speedy bony ankylosis in any tuberculous joint. This is the object of the treatment in tuberculosis of the spine. The technique of the Hibbs' and Albee operations is described. Any operation which will hasten the cure in these cases should be looked upon with favor.

In 1912 there were 35 cases of Pott's disease seen in the Mayo Clinic. Of these, 6 were operated on. The Hibbs' operation was used in three and the Albee operation in three. The age of the oldest patient operated on was 42 and that of the youngest, 3. The carrying out of support by braces after the operation was just the same as if no operation had been performed. Three of the patients were cases not controlled by conservative treatment prior to operation. Their course since operation has been one of steady improvement. Recumbency on a Bradford frame for at least one month after operation was insisted on. Following this, the use of a Taylor brace was required.

A detailed report of each case is given. It is stated that the report is essentially preliminary, but the results are encouraging.

MALFORMATIONS AND DEFORMITIES

Ludloff: The Open Reduction of Congenital Hip Dislocation by an Anterior Incision. *Am. J. Orth. Surg.*, 1913, x, 438. By Surg., Gynec. & Obst.

The author describes a method for the reduction of congenital luxations of the hip in those cases in which manipulative treatment has failed, or has been followed by a more or less complete relapse. The causes for these failures the author seeks in the pathologic anatomical relations of the congenitally dislocated hips, and his technique is designed to overcome these difficulties. His findings would show that, although the head may be so manipulated that it is placed in position upon the acetabulum, when the thigh is in extreme abduction and outward rotation, there are strong forces which act to relaxate the femoral head when the position of abduction and inward rotation is approached. These forces would seem to lie in the tension of the very strong upper and lateral parts of the joint capsule, and the tension of the ilio-psoas, when the head is placed in its new position.

These factors, combined with the flat acetabulum and tissues forced under the head by manipulation, cause the relaxation when abduction is attempted, and would, in certain cases at least, prevent firm anchorage.

The chief steps in the operation follow: With the patient on his back and the pathological thigh at right-angled abduction, an incision is made parallel to the axis of the femur from Poupart's ligament about 15 cm. downward on the lateral border of the abductor longus, leaving the pectineus and great vessels on the medial side. The exposed capsule is incised, and the tendon of the ilio-psoas is separated from the lesser trochanter and retained for later lengthening. The incision in the capsule exposes the acetabulum with the pathologic limbus and infolded membranes lying in front of the head. Incision of the isthmus and the limbus will allow the head to correctly enter the acetabulum, but adduction will produce relaxation. An incision of the lateral and upper parts of the capsule along the inter-trochanteric line permits of a position of 45° adduction and inward rotation without relaxation. With the head in this position, the capsule is sutured as far as possible, the ilio-psoas attached, and the wound closed. In the author's cases a plaster of Paris splint maintained this position for eight weeks, when the patient was allowed to walk with a high shoe under the well foot.

The theoretical question of the weakening of the capsule by extensive incision and incomplete closure is considered, but the practical results would seem to show that a compensatory fixation follows the operation.

In the three cases cited in the paper, good results have followed. All were relapsed cases, but following the open operation the reduction has been maintained in one case, two years; in another, one year; and in the last, nine months. Some antetorsion has followed in all the cases.

The author concludes from his experience that this method best deals with capsule and muscle tension described above, and that some method of deepening the acetabulum and strengthening the capsule would still further improve the results of the reduction.

W. W. PLUMMER.

Campbell: The Causation and Treatment of Deformities Following Anterior Poliomyelitis. *Edinb. M. J.*, 1913, x, 501.

By Surg., Gynec. & Obst.

This paper, in two parts, takes into consideration the etiology of deformities in infantile paralysis as well as the means at our disposal for the prevention, amelioration and correction of deformities which remain as a result of this disease. The author divides the etiological factors into two classes:

1. The *trophic* or *unpreventable* deformities which comprise those which occur as a direct result of the complete destruction of the ganglion cells by which is cut off the trophic influence to the part.

2. The *preventable* deformities which appear any time after the paralysis. These are not due, except indirectly, to the paralysis but are brought about

by outside forces acting on the weakened parts; they are not caused primarily by unbalanced muscular action but by a loss of *tone*, the force of gravity or the pressure of the body weight being too powerful for the paralyzed, toneless muscles. The antagonistic muscles find themselves relaxed and therefore contract somewhat to take up a position in which they will regain their tone. After constant repetition of the deformity the new tone becomes normal and the muscles are unable to relax to their former position. Constant contraction and disuse cause them to atrophy and in time fibrous changes take place which further exaggerate the deformity. While these changes are occurring in the unparalyzed muscles, the opposite is the case in those paralyzed: the latter are gradually more and more overstretched, and as a result healthy muscle fibers that have escaped paralysis, and the ligaments, bones and joints undergo secondary changes.

The treatment is taken up under two heads:

1. *Preventive treatment*, in which the most important procedure is to identify the paralyzed muscles as early as possible and retain the limb in such a position that they will be fully relaxed; after this a course of massage, electricity, muscle beating and other means of stimulation may be instituted. Plaster of Paris splints are not recommended on account of their weight and the impossibility of applying massage. The part should be retained in a slightly over-corrected position; the splint or apparatus should be worn continuously until it is evident that no further improvement will take place or the muscles answer to the tests of recovery; as soon as paralyzed muscles show some strength, voluntary action should be encouraged.

2. The *corrective or surgical treatment* deals with deformities which result from unsuitable treatment and those following treatment correctly carried out but unavailing because of the extent of the permanent damage to the nerve cells. In the former the paralyzed muscles may regain a considerable amount of power after the deformity is corrected and suitably treated but in the second class no such return of power can be expected. Measures for the correction of the former include the following procedures: Straightening of the part with the hand or Thomas's wrench, division of tendons and other contracted structures, the removal of skin areas and the taking in of relaxed tissues, osteotomy and the removal of portions of bone. The latter require

such measures as muscle and tendon transplantation, arthrodesis and nerve anastomosis.

In cases of extensive paralysis which do not respond to mechanical or medical measures and are unsuitable for surgical treatment, some form of apparatus can usually be found of advantage.

The author takes up in detail the consideration of each individual deformity, describing the methods of prominent authorities. ROBERT B. COFIELD.

Melchior: Madelung's Deformity of the Wrist
(Die Madelungsche Deformität des Handgelenks).
Ergebn. d. Chir. u. Orthop., 1913, vi, 649.

By Zentralbl. f. d. ges. Chir. u. i. Grenzgeb.

Madelung's deformity is of rare occurrence; only about seventy-five cases have been published. Melchior and others (Duplay, Siegrist) consider it probable that rachitis plays an important rôle in the etiology, as other rachitic phenomena usually accompany the deformity, especially the spreading and irregularity of the radial epiphysis. The early ossification of the ulnar end of the epiphyseal line may be the cause of the deviation of the joint. There is no luxation of the carpus, therefore the author discards all descriptions which refer to the "spontaneous subluxation of the hand anteriorly." The non-presumptive name "Madelung's deformity" is better, as the nature of the disease is not clear. The term itself should be applied only to the symptom complex described by Madelung himself and not to other wrist joint anomalies, such as hyperostotic thickening of the capitulum ulnæ, which frequently is normal or induced by arthritic processes, such as the habitual subluxations of the ulna.

The subluxations of the ulnæ which accompany stiffening of the radiocarpal joint or traumatic curvatures of the radius should not be considered as being the deformity in question, as the nature of the deformity depends not upon the external configuration, but upon the position of the distal end of the radius, in which the displaced ulna plays only a secondary rôle. The course of the deformity can hardly be influenced therapeutically. Pains occur only during the period of formation. After one to one and one half years the disease remains stationary and produces only cosmetic defects, which, however, cannot be influenced by osteotomies. In conclusion the author refers to the reversed form of the deformity, the "typus inversus," in which the radius has a dorsal concave curvature. SIEVERS.

SURGERY OF THE NERVOUS SYSTEM

Nové-Josserand, Savy and Martini: Malignant Cubital Neuroma (Névrome malin du cubital). *Provincie méd.*, 1913, xxvi, 231. By Journal de Chirurgie.

The authors report the case of a boy 2½ years old who had a tumor mass in his left arm the size of an orange, which was first noticed six months before. On examination hard, rounded nodules were found

all along the course of the great vessels of the arm. There was no axillary or subclavicular lymphadenopathy or functional disturbance.

At operation the tumor was found to have originated in the cubital nerve and to have extended by small neoplastic growths along the course of the nerve up to the axilla. Two years later there was a

recurrence in the axilla which was removed, but returned after 4 years. The patient died following the removal of this. These diverse neoplasms of the nerves of the arm, more commonly of the cubital than of the cubital and median, make it possible in the course of each operation to state what sort of neuroma is present.

This case presented the usual clinical symptoms as it began in the deeper tissues, gradually involved the more superficial and did not give rise to disturbances of function or general health.

The first tumor was excised with some of the nerve, the cut ends of which were brought together by catgut. The nerve soon functionated as is so frequently the case following excision of nerve tumors.

Histologically this tumor was a sarcoma of the cubital nerve and the question was, did it develop from the nerve fibers or the nerve sheath? The authors believe this to be a true neuroma developing from the sheath of Schwann and not from the fibrous tissue sheath. The tumor cells were intermixed with the nerve fibers and the sheath was intact. The tumor did not invade the neighboring tissues.

J. DUMONT.

Hunt: Sciatica and Its Treatment. *Med. Rec.*, 1913, lxxiii, 1153. By Surg., Gynec. & Obst.

The causes of sciatica may be grouped under four headings: (1) Intra-pelvic disease; (2) constitutional state; (3) damage to the nerve trunk; (4) damage to the sacro-iliac joint. Occupation is a factor in the production of sciatica — in this respect exposure, over-exertion and pressure enter into consideration.

The symptoms of sciatica are pain, gait, wasting of the muscles, tenderness of the nerve to pressure, sometimes loss of the knee jerk. The course of sciatica is long, tedious and discouraging.

The treatment must depend upon the cause. If rheumatic, diabetic, or due to pressure, the remedies must be in proportion. If there is no discoverable cause, treat it as a primary neuritis. Rest, protection to the leg, and counter-irritation are the most valuable remedies, while cupping and leeches help, but the Paquelin cautery is preëminently the best of all local remedies. If the case is severe inject 100 cc. of normal saline solution into the sciatic nerve. The injection may be either below the knee in the peroneal branch or above in the main trunk. Baths of all kinds are of benefit. Hot air is questionable. Hypodermic injections of morphine and cocaine are dangerous. Massage may help. Stretching the nerve should be relegated to the list of remedies of last resort. As far as medication is concerned the list is large; castor oil, strychnia and methylene blue are valuable. The most important thing of all is to keep up the general health of the patient. To attain this end resort to nerve foods, tonics, and especially fat-producing foods. Avoid alcohol. Give attention to the after-treatment and do not discharge the patient too early.

De Luca: Action of the X-Rays on the Peripheral and Central Nervous System. *Arch. Rönt. Ray*, 1913, xviii, 9. By Surg., Gynec. & Obst.

To test the sensitiveness of central and peripheral nervous tissue to X-rays, experiments were made on white mice and guinea pigs. By protecting all except a small area over the brain, spinal cord, or sciatic nerve and by protecting these superficially with filters, massive doses were given without grave constitutional effects and with no local effects beyond epilation. In no case did the irradiation result in paralysis or even minor motor disturbances.

These researches help to prove that the nerve cell and fiber elements are at the lower end of the scale of radio-sensibility. This agrees with the previous findings that cells with higher and fixed functions such as are found in the retina, nerves, muscles, etc., are relatively immune to the action of X-rays. Such tissues are incapable of regeneration and are to be contrasted with tissues containing "young" cells such as are seen in the liver, bones, and genital glands, particularly in their growing or multiplying stages.

It has been argued from these facts that it is the nuclein content which determines the radio-sensibility of all cells and by this measure nervous tissue would be classified low in the list on account of its small proportion of chromatin elements.

HOLLIS E. POTTER.

Oehlecker: The Symptomatology and Surgery of the Disturbances of the Phrenic Nerve (Zur Klinik und Chirurgie des Nervus Phrenicus). *Zentralbl. f. Chir.*, 1913, xl, 852.

By Zentralbl. f. d. ges. Chir. u. i. Grenzgeb.

On the basis of a number of observations the author comes to the conclusion that in inflammatory conditions and in mechanical irritation of the endings of the phrenic nerve in the diaphragm a pain in the shoulder of the same side is felt. Mayo-Robson was the first to point out that pain in the back of the neck is a symptom in super-renal neoplasms transmitted by the phrenic nerve. Oehlecker observed such pains in a case of hæmorrhage in the right subphrenic space in a case of perforated gastric ulcer with an exudate in the left subphrenic space, etc.

The irritation upon the periphery of the phrenic nerve is transmitted by the central ganglion to neighboring sensory nerve roots, especially to the shoulder, as the principal part of the phrenic nerve rises from the fourth cervical root. Oehlecker attaches significance to the motor part of the phrenic nerve. Following the suggestion of Stuert, he divided the phrenic nerve in diseases of the lower part of the lung, in which, on account of pleural adhesions, a collapse of the lung cannot be obtained. He performed the phrenicostomy in three cases and gives details of the technique. He does not believe that the side reactions incident to the Kulenkampf plexus anæsthesia, as described by Sievers and others, are due to irritation or paresis of the phrenic nerve.

HIRSCHEL.

DISEASES AND SURGERY OF THE SKIN AND APPENDAGES

Davis: Excessive Thickening of Thiersch Grafts Caused by a Component of Scarlet Red (Amidoazotoluol). *Bull. Johns Hopkins Hosp.*, 1913, xxiv, 178. By Surg., Gynec. & Obst.

In the first place, Davis states that he is fully convinced of the power of epithelial stimulation of certain of the organic coloring matters, namely, scarlet red, soudan III, azodolen, pellidol, etc., when applied locally to granulating wounds. During the past four years a number of enthusiastic articles have been published by well-known investigators on the satisfactory use of these substances. These papers almost uniformly report splendid clinical results in hastening the healing of sluggish granulating wounds of varying etiology, and in every situation.

The use of these coloring matters has also been objected to by some on the ground that there might be the possibility of producing epithelial overgrowths having malignant characteristics. Davis states that the consensus of opinion, deduced from experimental and clinical work, is that such danger is not great. However, he sounds a note of warning against the indiscriminate use of these substances by inexperienced persons, and he reports a case in which there was an overgrowth of epithelium following the use of amidoazotoluol in ulcers due to a burn in which Thiersch grafting had been employed. The patient has been under observation for over two years and a half since his discharge from the hospital, and there is no sign of malignant degeneration anywhere. The skin, however, shows a distinct overgrowth of epithelium of a pebbly formation.

GEORGE E. BEILBY.

Sutton: The Occurrence of Cancerous Changes in Benign New Growths of the Skin. *Am. J. M. Sc.*, 1913, cxlv, 819. By Surg., Gynec. & Obst.

The author supports the view of McDonough, who has made a study of the skin from the eyelids and the naso-facial grooves, and who thinks that all new growths of these regions are atavistic. The author reports two cases in support of his views.

The first case is that of a woman who for about thirty-five years had had warty growths varying in size from a millet-seed to an English walnut, which gradually increased in number, until in 1906 she had more than seventy, distributed asymmetrically over her face and chest. One was sectioned and found to be a typical acanthoma adenoides cysticum of Brooke. One year ago a small cystic tumor appeared at the inner canthus of the eye, which in the course of a few weeks broke down and extended peripherally. Despite treatment clinically it could not be distinguished from epithelioma. The second case is the daughter of the woman whose case is reported above. In 1905 she noticed some small flat-topped moles upon her forehead, which were pink in color, painless, irregularly distributed and slowly increasing in number. They remained stationary after attaining the size of a grain of wheat, except one located upon the right cheek which broke down in January, 1911, and was excised. It was found to be typical of rodent ulcer. Practically all of the other tumors have been removed by Pusey's carbon-dioxide snow.

Tumors so closely allied in histological structure and origin occurring in mother and daughter, point at least to a clinical relationship between acanthoma adenoides cysticum and rodent ulcer. H. A. POTTS.

MISCELLANEOUS

CLINICAL ENTITIES — TUMORS, ULCERS, ABSCESSSES, ETC.

Sykoff and Nenjukoff: Malignant Tumors from the Biological Standpoint (Die bösartigen Neubildungen vom biologischen Standpunkt aus). *Nowoje w Med.*, 1913, vii, 65.

By Zentralbl. f. d. ges. Chir. u. i. Grenzgeb.

Three general biological laws may be set down: 1. Carcinomata occur during old age and sarcomata during youth. 2. In some species the tendency for epithelial formation is greater, while in others connective tissue tumors prevail. 3. There are certain animals in which malignant tumors do not occur at all, as sheep, mules and geese. In explanation of the first two laws several biological facts are cited. The temperature of the animals plays a rôle; in mammals with low body temperature epithelial tumors develop more easily. In birds, however, which have a body temperature of 41-44° degrees connective tissue tumors are more prone to develop. On the

other hand, embryonal rests, variations in metabolism, and the lowering of oxidation processes also play an important rôle.

The present investigations have been conducted in regard to the oxidation ferments of tissues in general, and in malignant growths in particular. The ferments are classified into katalases, peroxidases and oxidases. The author then gives in detail his method and the results of his investigations.

He carried out a total of 100 experiments and came to the following conclusions: 1. Peroxidase is decreased in cancer cells and increased in sarcoma cells. 2. Katalase is decreased in cancer cells but not in sarcoma cells. 3. The degree of decrease and increase is apparently in relation to the maturity and malignancy of the new growth. 4. The nuclear substance of the cancer cell is changed. 5. Electrochemical investigations make it probable that we are dealing with alkali products in the cancer cell

and with acid products in the sarcoma cell. 6. The usual relation between nucleus and protoplasm is disturbed in the cell of malignant new growths. 7. The cells of carcinoma and sarcoma are differentiated by their chemical and biological characteristics not only from the cells of normal tissues but also from each other.

SCHAACK.

Nowell: An Etiological Factor in Carcinoma and Its Possible Influence on Treatment. *Boston M. & S. J.*, 1913, clxviii, 838. By Surg., Gynec. & Obst.

For more than a year the author has been investigating the etiology of carcinoma. While the results are not final, he reports the facts as they are at present. The experiments have been carried out with great care and each has been accurately controlled.

The author states that it is a well-known fact that carcinoma develops in the waning years of activity, at a time when there is a marked metabolic change going on synchronously with other retrogressions. With a diminution of the metabolic there is a similar decrease in the excretory functions. As long as the change in one parallels the other the equilibrium of earlier years is maintained, but if through some cause the excretory function suffers a more rapid impairment, an accumulation of waste products in the system must inevitably result. Such an accumulation operates unfavorably on the general organism and possibly might produce in a given group of cells a morbid activity, thus forming other and deleterious wastes. Further, should some extraneous cause operate to produce waste matter in excess of the impaired eliminative machinery, the result would be the same.

In this connection the author brings out the fact it is conceded by many that malignant growths are primarily of traumatic origin. Traumatism here is used in the broadest sense, to mean the filling up of a gland causing mechanical pressure, the formation of scar tissue; in short, anything that tends to produce irritation. Wherever there is an injury, nature rushes to the front; greater cellular production takes place, the extent depending on the health of the individual. If, however, the control of this production is abnormal, the increase may be so great as to cause pressure which, in turn, breaks down the surrounding tissue by affecting the blood and nerve supply. Under certain conditions these degenerative changes may result in a further production of deleterious chemicals. As it has been established that certain waste products have a decided action on the inhibitory centers, it is reasoned that in the above condition cellular production might be subject to a constantly decreasing control resulting in a constantly increasing velocity of growth. Thus directly through the impaired elimination of normal waste, or indirectly by the formulation through exogenous causes of abnormal waste, groups of cells might be excited to a pernicious activity. This, in turn, might be productive of other deleterious wastes through which the control of the nerve centers regulating

cell growths might be injuriously affected and the exercise of their function inhibited. Finally, such inhibitory effects would possibly show progressive characteristics, as the influence would propagate its own cause.

The author states that if this theory of the origin of carcinoma is correct, then the tumor, or the tissues undergoing these pernicious changes, should contain the toxic substances responsible for their continued growth and propagation. A failure to isolate such substances would not wholly prove their absence, as they might readily be compounds of such intense toxicity that the observed effects could be produced by quantities far less than could be detected by any chemical means. If, however, appreciable amounts of the toxine or toxins are present, they should be susceptible of isolation. It is along this line that the author has conducted his experiments.

Briefly, he uses the following procedure in isolating the toxic substance from the tumor tissue, after it has been proven malignant by clinical and histological findings. The freshly extirpated growth was carefully freed from fat and extraneous tissue, cut into small pieces and digested in water at 100° for many hours. The solution was filtered and the filtrate acidified and boiled. The soluble proteins were thus removed. The protein-free filtrate was exactly neutralized and evaporated to a syrup. This was carefully extracted with pure alcohol and the extract, after the removal of the alcohol by distillation, was repeatedly treated with ether. The residue was then dissolved in water, strongly acidified and again thoroughly extracted with ether. The extracts were then collected and the solvent removed by distillation. The residue was dissolved in water, rendered alkaline, boiled for half an hour and again filtered. On spontaneous evaporation, long white needle-shaped crystals separated. These were purified by repeatedly washing in water. The crystals in the purified form were the basis on which Nowell's conclusions were drawn. The exact nature of the crystals has not been determined. As they have been freed from all organic life any results which may be obtained by their use must be referable to the inherent chemical nature and not to the presence of organized life in any of its manifold forms. All the solutions used were carefully sterilized.

The author conducted many experiments with the rabbit and guinea pig. The results are fully described. He comes to the following conclusions:

1. A procedure has been developed whereby a substance or substances may be isolated from carcinomata, the method precluding the presence of organic life in the end product.
2. This end product has been shown to be of a highly toxic character.
3. The peritoneal exudate produced by a fatal intoxication is far more toxic than the original substance.
4. The tumor substance has been shown to possess not only a general but also a specific tox-

icity, since on injection into rabbits in doses of less than lethal amount it will produce well-defined, well-characterized carcinomata, the site of the primary lesion being different from and independent of that of the injection.

5. The appearance of the primary lesion is followed by the development of numerous metastatic foci in different parts of the body, while the characteristic cachexia manifests itself.

6. The poisonous tumor preparation has been shown to be characteristic of carcinomata.

7. By the repeated injection of very small doses a large number of rabbits have been immunized.

8. The serum from the animals thus immunized possesses the power of antagonizing the toxic action of the tumor substance. This has been demonstrated by injections of the serum either previous to or simultaneous with that of the tumor poison. In both events no effect is observed from quantities of the poison, which, if injected alone, would produce a rapidly fatal intoxication.

9. With the simultaneous injection of poison and antibody it has been shown that one part of the latter will effectually antagonize 99 parts of the former.

EDWARD L. CORNELL.

Syssojeff: Myeloma (Zur Lehre von Myelom). *Chir. Arch. Weljaminowa*, 1913, xxix, 348.

By Zentralbl. f. d. ges. Chir. u. i. Grenzgeb.

The article represents a microscopical study of myeloma. On the grounds of these careful investigations the author denies the occurrence of true metastases in cases of myeloma of the bone marrow. Myeloma is to be considered as a disease affecting the whole hæmatopoietic apparatus—a hyperplasia of the bone marrow cells. The so-called metastases described by former authors ought to be looked upon as pseudometastases. The latter are hyperplastic conditions of the lymphoid tissues, but these are to be found also in the internal organs under normal conditions.

HESSE.

BLOOD

Whipple and Hooper: Hæmatogenous and Obstructive Icterus; Experimental Studies by Means of the Eck Fistula. *J. Exp. Med.*, 1913, xvii, 593.

By Surg., Gynec. & Obst.

In studying the various types of icterus the authors made use of the Eck fistula. To simulate hæmatogenous jaundice, laked red cells were injected intravenously into control and Eck fistula dogs, and the urine examined at frequent intervals for the time of appearance, relative amounts and duration of excretion of the hæmogoblin and bile pigments. The reaction is in no way influenced by the Eck fistula although the blood supply to the liver is reduced to about 25 per cent of the normal. Practically the same results were obtained in normal and Eck fistula dogs when a hæmatogenous jaundice was produced by chloroform anæsthesia.

Simple obstruction to the common duct, combined with an Eck fistula gives rise to a definite low grade icterus with bile pigment constantly present in the urine. This observation does not harmonize with the view that bile pigments are formed solely from hæmoglobin, as there is no evidence of more hæmolysis in a normal than in an Eck fistula dog. This suggests to the authors that the bile pigment may be formed in part, at least, from other substances than hæmoglobin, and, further, that bile pigment formation may depend in part upon the functional activity of the liver cell rather than upon the amount of hæmoglobin supplied to it.

J. F. CHURCHILL.

Whipple and Hooper: A Rapid Change of Hæmoglobin to Bile Pigment in the Circulation Outside the Liver. *J. Exp. Med.*, 1913, xvii, 612.

By Surg., Gynec. & Obst.

The object of this communication is to submit evidence to show that hæmoglobin can be transformed into bile pigment when the liver has been excluded from participation in the reaction. To show this, the liver was excluded by means of an Eck fistula and ligation of both branches of the hepatic artery. The animal was then injected with laked corpuscles drawn from its own circulation. These animals died in four to six hours of hepatic insufficiency.

In another series of experiments, the liver, spleen, and intestines were excluded; and in a third series, the circulation was restricted to the head and thorax. The authors summarize the results as follows:

The intravenous injection of red cells obtained from the same animal and laked by distilled water is similar to certain types of hæmolysis which result in hæmatogenous jaundice. This procedure cannot be criticized on the grounds of introducing toxic substances. The hæmoglobin circulating in the blood stream is rapidly changed, in part at least, to bile pigment. The change goes on with practically the same rapidity in the normal circulation, in an Eck fistula animal, and in a dog with Eck fistula and hepatic artery ligation. Moreover, the bile pigment formation goes on in a dog whose liver, spleen, and intestines have been shut out of the circulation, and in those with a head and thorax circulation. In the last experiments there had been no operative manipulation of the liver and the bile pigment could not have escaped from the liver and have been absorbed by the circulation above the diaphragm; for example, by the thoracic duct. It is possible that the endothelium of the blood vessels is the agent which brings about the rapid change of hæmoglobin to bile pigment. This mechanism probably comes into play when there has been a destruction of many red cells with much hæmoglobin free in the plasma. The conclusion is reached that in dogs, at least, hæmoglobin can be rapidly changed into bile pigment in the circulating blood without the participation of the liver.

J. F. CHURCHILL.

Weber: Intravenous Injection of Small Quantities of Human Blood for the Treatment of Severe Anæmia (Über intravenöse Injektionen kleiner Mengen von Menschenblut bei der Behandlung schwerer Anämien). *München. med. Wchnschr.*, 1913, lx, 1307. By Zentralbl. f. d. allgem. Chir.

During the last four years forty-six intravenous injections were given to eighteen patients at the medical clinic at Giessen. In order to avoid untoward symptoms, the blood was kept for twenty-four hours in the ice-box. The dosage was 5 ccm. and was given repeatedly. Larger quantities cause stronger reactions, such as an increase of temperature, chills, quickening of pulse and breathing. Fifteen cases were treated with combined injections of serum and arsenic. The results were good. Three cases which were treated only with the injection of serum are reported in detail.

An extraordinary improvement of the general condition and the blood occurred in two cases of pernicious anæmia, while in a third case of severe anæmia only the general condition improved and the blood did not show any marked improvement.

WORTMANN.

Von Saar: Employment of the Momburg Tube in Cases of Hæmorrhage (Über Blutleere der unteren Körperhälfte). *Ergebn. d. Chir. u. Orthop.*, 1913, vi, 1.

By Zentralbl. f. d. ges. Chir. u. i. Grenzgeb.

The author analyzed 400 cases in which the Momburg tube was employed and comes to the following conclusions: (1) The small intestine adapts itself very easily; the colon, however, is always compressed in its ascending and descending parts, hæmorrhages and contraction scars having been observed frequently at autopsy. In non-fatal cases mucous diarrhoea and hæmorrhage have been observed commonly due to mechanical injury to the walls of the bowel. (2) In the urinary system compression of the ureter is most important; the kidneys usually lying above the point of application of the tube. Transient retention of the urine occurs, but a permanent injury of the kidney does not result, although one fatal case due to anuria occurred following the application of the tube for $\frac{3}{4}$ of an hour. (3) The advantage of the tube lies in the compression of the aorta and vena cava anterior to the third lumbar vertebra. (4) Injury to the suprarenals was observed once in the human, but more frequently in animal, experiments. The fatal case due to anuria showed fresh areas of fat necrosis in the pancreas. Indirect injury to other organs may occur such as sudden death due to cardiac dilatation incident to sudden changes of blood pressure. In cases of broken compensation the danger is still greater. On account of the severe pain, anæsthesia is necessary. The indications for and against the procedure are given. The Momburg tube should not be employed in every case of hæmorrhage but only in selected cases and for vital indications. HORTZ.

Fonio: Arrest of Hæmorrhage and Treatment of Wounds with Coagulin Kocher-Fonio (Über die neue Blutstillungsmethode und Wundbehandlung durch das Koagulin Kocher-Fonio). *Cor.-Bl. f. Schweiz. Ärzte*, 1913, xliii, 385.

By Zentralbl. f. d. ges. Gynäk. u. Geburtsh. s. d. Grenzgeb.

Many theories explaining the origin of blood coagulation are fully discussed. They all coincide in the following: Two or three elements combine with each other to form the active agent causing coagulation. As soon as this occurs coagulation begins in the presence of sodium salts. To prepare a reliable stypctic Fonio attempted to isolate one of these active substances from blood-plates. By fractional centrifugation he extracted a liquid from blood discs which were sterilized by boiling. This substance which accelerates and increases coagulability is termed coagulin Kocher-Fonio. The bleeding surface is sponged and the coagulin applied to it with a record syringe. On the basis of 77 operation reports, coagulin is credited with causing immediate hæmostasis, which is of special advantage in bloody operations, but also of possessing a secondary action which prevents secondary hæmorrhages.

In conclusion Fonio discusses the far-reaching possibilities of the remedy. He believes that in connection with the usual methods of treatment it may be of decided advantage in post-partum hæmorrhages due to uterine atony, in placenta prævia and in abortions by producing a rapid and lasting coagulation. Coagulin, which is manufactured by the Gesellschaft für chemische Industrie in Basel, has not yet been introduced in commerce, as it is being still further subjected to tests in the surgical clinic at Bern. BECKER.

Schreiber: The Checking of Internal Hæmorrhage by Means of Intravenous Injections of Grape Sugar (Über Stillung innerer Blutungen durch intravenöse Traubenzuckerinjektionen). *Therap. d. Gegenw.*, 1913, liv, 195.

By Zentralbl. f. d. ges. Chir. u. i. Grenzgeb.

Schreiber by means of intravenous infusions of about 200 cmm. of a 5-20 per cent solution of grape sugar was able to check gastric hæmorrhages as well as hæmorrhage in typhoid cases. He describes the method as being similar in effect to the action of Velde's intravenous injection of hypertonic salt solution and sees in the grape sugar injection a definite advantage on account of its nutritive value.

VON DEN VELDEN.

Froelich: Hæmorrhage from the Axillary Artery Three Months after Trauma; Ligation of the Artery; False Volkmann's Ischæmic Paralysis (Hémorragie foudroyante de l'axillaire trois mois après sa blessure; ligature de l'artère; fausse paralysie ischémique de Volkmann). *Rev. méd. de l'Est.*, 1913, xlv, 294. By Journal de Chirurgie.

The author reports the case of a boy 11 years old who was injured in the axilla by a fragment of wood in August, 1912. There was a severe hæmorrhage

which ceased spontaneously. Several days later a physician was consulted regarding an abscess which had developed in the axilla and opened spontaneously discharging a piece of wood. A fistula persisted and from time to time there were slight hæmorrhages preceded by severe attacks of pain. After entering the hospital the fistula was irrigated regularly and an X-ray picture was made which showed no changes about the shoulder.

November 12th, there was a more severe hæmorrhage than usual preceded by very severe pain, and on the 14th another copious hæmorrhage. The child was chloroformed, the axilla opened and a suppurating pocket found in which there was a piece of wood 3 by 1 cm. Blood was coming in spurts from the axillary artery but the hæmorrhage was stopped by pressure on the subclavian. On the 15th, the pressure was removed and the hæmorrhage did not recur until the 19th, when it was very severe. The axillary artery was ligated below the small pectoral muscle under the clavicle.

Serum was injected as the child was exsanguinated, the pulse gone and the arm cold. This coldness persisted for three days after which its temperature became normal. The arm was painful for ten days and paralysis of the flexor and tensor muscles followed. The flexors rapidly regained their function but the paralysis of the extensors remained.

This made it appear to be a Volkmann's ischæmic paralysis following ligation of the axillary artery. As a matter of fact there was only a radial paralysis and the contracture was due to lack of action in the antagonistic muscles. The fact that the thumb and fingers could be put passively in hyperextension proves it, as this is impossible in ischæmic paralysis. From the electrical examination it seems that the radial paralysis will be cured.

J. DUMONT.

Baum: Traumatic Venous Thrombosis in the Upper Extremity (Die traumatische Venenthrombose an der oberen Extremität). *Deutsche med. Wchnschr.*, 1913, xxxix, 997.

By Zentralbl. f. d. ges. Chir. u. i. Grenzgeb.

Traumatic venous thrombosis occurs more commonly in the arm, much rarer in the lower extremity. The general practitioner sees these cases oftener than the surgeon. The clinical picture is not generally known, and is frequently taken for muscle injury, muscle inflammation or neuritis. The condition occurs commonly after an indirect injury to the arm, even though a mechanical, chemical or infectious injury to the wall of the vein did not take place. The onset is more or less sudden with closure of one of the large veins. The trauma may be very slight, frequently not greater than ordinary muscular action.

There have been only seven cases of traumatic venous thrombosis of the upper arm published. After severe muscular action the signs of venous stasis appear. A compensatory circulation in time develops, due either to absorption of part of the thrombus or to the establishment of a collateral

circulation. The return of function of the arm depends more or less on the re-establishment of the circulation. Etiologically the condition is due to accumulation of blood platelets and thrombus formation as a result of injury to the vein and interference with the blood-stream. Even in the axillary vein it seems possible that thrombosis formations can occur as a result of severe muscular strain.

In regard to life the prognosis is favorable, especially if the thrombus is not disturbed. Embolism has never been observed. The prognosis in so far as restitutio ad integrum is concerned is decidedly bad, as the collateral circulation is usually insufficient. Venous stasis occurs, which is easily aggravated, and which interferes with the working capacity of the arm to a greater or less degree.

DE AHNA.

Major: The Wassermann Reaction in the Johns Hopkins Hospital. *Bull. Johns Hopkins Hosp.*, 1913, xxiv, 175.
By Surg., Gynec. & Obst.

The Wassermann reaction, as Major states, has been extensively employed in the Johns Hopkins Hospital in the past four years, and their experience with it confirms the result of a host of workers as to its reliability and specificity as a diagnostic procedure. The first report upon its use in that clinic was made in 1910 and the present report includes the cases from September, 1911, to August, 1912, in which the reaction was employed. In all, 1200 patients were examined, the great majority of whom were medical cases. This number includes a great variety of diseases ranging from outspoken cases of syphilis to neurasthenic patients, in whom the reaction was made for the purpose of excluding lues. The series includes also a great variety of functional and organic nervous and cardiac diseases, nephritis, diabetes, pneumonia, typhoid fever, gastro-intestinal diseases, and a fairly large number of cases of brain tumor.

Of these 1200 cases, 239, or 20 per cent, gave positive reactions, while 961, or 80 per cent, were negative. Of the cases giving positive reactions, 55, or 24 per cent (nearly $\frac{1}{4}$) gave no history of a primary sort. The percentage of negroes in the above figures is of some interest. The Wassermann reaction was performed upon 185 negro patients, the great majority being cardiac or cardio-renal cases, but including also other more uncommon diseases. Of this number, 61, or approximately 34 per cent, gave positive reactions, while 124, or 66 per cent, were negative. When this number is compared with the reactions on white patients, it is seen that 34 per cent of negroes compared with 17 per cent of whites, give a positive reaction. This indicates a frequency of positive reactions in negroes twice that of the whites. These figures do not perhaps give a sufficient indication of the greater frequency among negroes, since the total number of reactions performed on the sera of colored patients is considerably less than that on whites.

The Wassermann reaction in forty-two cases of aortic insufficiency showed twenty-one, or 50 per

cent, positive reactions. Of the twenty-one negative cases, all but six gave a history of rheumatic fever, four of the six showed marked arteriosclerosis, and one patient died of an acute aortic endocarditis.

The reaction was applied in twenty-two cases of aneurism, mostly of the aortic arch. Twenty-one, or 95 per cent, gave positive reactions. The patient who gave a negative reaction was a negro who had a definite history of syphilis seven years before. His serum was tested one month later after antiluetic treatment with the same result.

In 17 cases of tabes the Wassermann reaction showed eleven, or 64 per cent, positive. Three of these patients gave a negative serum reaction, while the cerebro-spinal fluid was positive; and three of the patients having positive serum reactions showed negative reactions in the cerebro-spinal fluid. Eight of the patients admitted luetic infection; nine gave no history.

Thirteen cases of general paresis were tested. Twelve, or 92 per cent, of this number were positive. The cerebro-spinal fluid was positive in every case examined (seven), while the blood was negative in seven cases. Nine of the 13 gave a luetic history.

The Wassermann reaction was done with the serum of 59 cases of various types of brain tumors, including gliomata, hypophyseal tumors and cysts, cerebellar tumors and cysts, and tumors of the spinal cord; all were negative results. In seven of these the test was negative also with the cerebro-spinal fluid.

The author summarizes his study as follows: "The past year's experience with the Wassermann reaction in this clinic confirms our faith in the reliability and specificity of this reaction. The only other diseases in which positive reactions have been reported (trypanosomiasis, yaws, scarlet fever, leprosy, and possibly malaria) are either so easily diagnosed or so uncommon here as to cause no confusion. Wassermann states that he and his assistants have performed over 10,000 examinations and never yet made a false diagnosis. While the number of patients in our series is much smaller, we feel that we have not made a false diagnosis the past year when the diagnosis of syphilis was placed after the names of 239 patients who showed a positive Wassermann reaction." GEORGE E. BEILBY.

BLOOD AND LYMPH VESSELS

O'Day: Arteriorrhaphy. *Northwest Med.*, 1913, v, 154.
By Surg., Gynec. & Obst.

There are two important principles to be observed in order to suture blood vessels successfully: first, perfect apposition of serosa to serosa, and second, that no trauma be inflicted upon that part of the vessel surface which is to come into contact with the blood stream. The methods of Payr, Carrel and Murphy do not neglect these principles, yet the author feels that since the occasion for vessel suture in the hands of the everyday surgeon comes only in emergency cases and since he may not be able to

successfully master the technique evolved by these men, he may follow a simpler procedure, as the author has done in one case, with success. In reuniting severed arteries, one very great difficulty is to overcome the retraction of the stumps.

The technique used with success by the author in his one case and subsequently bettered by animal experimentation is as follows:

Free the stumps and wash away all débris with normal salt solution. Apply rubber-covered Crile clamps to either stump and if filling and pulsation occur just back of proximal clamp, the operation may be begun. Never allow the field to become dry, but keep well moistened with normal salt. The suture material may be either chromicized 20-day catgut or preferably Pagenstecher linen, the size ranging from No. 00 to No. 1, depending upon the vessel.

Four even lengths of suture are cut and with the assistant holding one, one of the others is tied to it in the exact middle and the other two at distances representing one fourth the vessel circumference. The assistant now passes his suture to which the three are tied around the proximal stump at sufficient distance from its end to insure the turning back of a cuff adequate to good serous apposition, and makes it secure, lightly constricting the vessel wall.

The cuff is now turned back and fixed by fan-shaped sutures made with a needle on the free ends of each of the above placed sutures. The distal stump is then made to receive the cuff after the method of Payr, and a running stitch engaging a good bite is then carried around, sewing the distal stump well to the margin of the cuff. If the vessel be large, a circular tie may add an extra reinforcement; otherwise this completes the work.

The distal clamp is removed first and then the proximal clamp is gradually released. The sheath is sutured over the reunited vessel. The ligature will not cut into the intima unless too great constriction has been imposed. Exudate soon covers all the sutures.

FLOYD B. RILEY.

Swetchnikoff: The Action of Adrenalin upon the Peripheral Vessels (Über die Adrenalin-wirkung auf periphere Gefässe). *Dissertation*, St. Petersburg, 1913. By Zentralbl. f. d. ges. Chir. u. i. Grenzgeb.

The author studied the action of adrenalin upon peripheral vessels according to the newer method of measuring vasomotor influences devised by Krawkoff and Pissemski, and comes to the following conclusions: (1) gradual variations of blood pressure do not influence the action of adrenalin materially; with very weak adrenalin solutions and very high vascular pressure, dilatation is observed; with sudden increase of pressure a dilation of the vessels is observed regularly, which occurs also following an infusion of Locke's solution even upon addition of adrenalin, the action being all the more pronounced when the action of adrenalin is weakest. Rhythmic variations of vascular dilation are observed due to

variations of vascular tone. (2) The fresher a solution of adrenalin is the more pronounced will its action be; even minutes are important in this respect. In continuous infusion of adrenalin solution, a prolonged contraction of the vessels occurs first, which gradually recedes in favor of dilation; but if a fresh solution is again introduced, prompt contraction again occurs. (3) Room temperature and light weaken the adrenalin solution in Locke's solution. Long standing solutions may act as dilators to the vessels. Oxygen has no influence. At body temperature the vasoconstrictor action of such a solution is materially decreased. A temperature of 60–80 degrees C. for a half hour changes the action of the solution to a vasodilating action. (4) The slight decomposition which occurs in such solutions is due to the alkalinity of the Locke's solution. In neutral physiologic salt solution adrenalin is stable for a considerable time. Physiologic salt solution itself acts as a vasoconstrictor. (5) Blood serum and blood plasma also produce a gradual but prolonged vasoconstriction, the action of the serum being more marked than that of the plasma. Addition of serum to an adrenalin solution prevents decomposition of the solution. (6) Addition of small amounts of formaldehyde decreases the vasoconstrictor action of the adrenalin solution. (7) Lactic acid and chloroform when added to the adrenalin solution also decrease the effect of the latter appreciably. (8) Ergotoxin solutions produce a paralysis of the vasoconstrictors which is not affected by the addition of adrenalin. The action of adrenalin therefore seems to be exerted upon the sympathetic nerves. (9) By increasing the temperature of the adrenalin solution its action is gradually lost: at 36 to 39° C. its action is weakened, at 41–45° C. the vasodilating action of adrenalin becomes marked. This is not due to a decomposition of the adrenalin but to a special behavior of the vessels to adrenalin at higher temperatures. Several experiments were conducted with the preparation "Imido." It was shown that in weak solutions the vasoconstrictor action appears slower than with adrenalin but it is much more prolonged. Locke's solution, higher temperatures, even boiling for fifteen minutes and age of the solution do not weaken its action. Several tables and an extensive bibliography are appended. STROMBERG.

Jacob: Intradermal Lymphatic Varices in the Inguino-crural Region (Varices lymphatiques intradermiques de la région inguino-crurale) *Bull. et mem. Soc. de chir. de Par.*, 1913, xxxix, 606.

By Journal de Chirurgie.

The author presents a case of varices of the lymphatic capillaries of the skin. The main lymph channels and glands are not affected and so the condition must not be confounded with adenolymphocele. The actual lesion demonstrated is as a matter of fact a recurrence of a similar condition which was removed four years before by a radical operation removing both the skin affected and the inguinal lymph glands. Microscopical examination

shows that each is a dilated end of a lymph capillary. It was thought that as the patient had been to New Caledonia and the disease had started after his return to France it might be due to filaria but none could be demonstrated. There was no history of dermatitis, erysipelas, lymph-angitis or adenitis of the inguino-crural region.

Auvray reports a case in which a similar condition was present in the cutaneous lymphatics of the right arm of one suffering from a painful lymph angitis of the arm. In this case a persistent fistula formed from one of the varices and a large amount of lymph escaped. An apparent cure after four years of observation was produced by complete excision followed by X-ray treatments. J. DUMONT.

Syms: Lymphangioplasty: Handley's Method.

Ann. Surg., Phila., 1913, lvii, 785.

By Surg., Gynec. & Obst.

Syms' article consisted in a review of the literature relative to an operation called lymphangioplasty by Handley, with a report of its use in two cases of his own. Handley's operation was originally intended to relieve the brawny arm of breast cancer and similar condition of lymphatic oedema. The method consisted in producing new lymph channels by inserting silk threads subcutaneously. The tissues of the arm are drained by two long U-shaped lines of silk, each line composed of two threads of No. 12 tubular silk. These are inserted through a small incision on anterior surface of the wrist by means of a long probe with an eye at its end for threading silk. Probe is passed along the ulnar and radial sides of the arm emerging at the posterior border of the deltoid muscle. The same procedure is carried out on the posterior surface of the arm. From the opening at the posterior border of the deltoid the silk threads are passed to the scapular region of the opposite side, and others to the lumbar region of the same side. The small incisions are closed with horse hair sutures.

The author found twenty cases of brawny arm reported. Of these, nine were reported as successful, nine as failures, and in two results were not reported. The author's case was a failure so far as results were concerned. In seventeen cases where lymphangioplasty was tried for elephantiasis there were seventeen failures. In chronic oedema of leg, two cases were improved and one cured. In three cases of chronic oedema of face and eyelids, a cure was reported in all three. According to Syms, the use of this method of draining ascites was first described by Lambotte in 1905. It has been used alone or combined with the Thalma's or Ruotte's operations with variable success. The author's case of ascites due to cirrhosis of liver, in which he did an omentopexy plus lymphangioplasty; he secured a marked improvement for a time but patient died in collapse after fifteen days. It is the author's belief that the operation merits a more extensive trial, as some cases show undoubted results.

R. W. MCNEALY.

Bylim-Kolossowsky: Drainage by Means of a Thread According to Handley in a Case of Elephantiasis (Ein Fall von Fadendrainage nach Handley bei Elephantiasis). *Verhandl. d. wiss. Ver. d. Ärzte d. städt. Obuchow-Krkh.*, St. Petersburg, 1913, xxii, 1. By Zentralbl. f. d. ges. Chir. u. i. Grenzgeb.

The author reports a case operated according to the Handley method. The patient before operation suffered from frequently recurring ulcerations and pains in the diseased leg. He was able to lift the limb only with the aid of his hands. Since the operation he has been entirely well. In ten months the circumference at the lower third of the leg has decreased ten cm. and the patient is able to lift it without difficulty. The mushroom-like growths have entirely disappeared.

VON SCHILLING.

POISONS

Davis: Interrelations in the Streptococcus Group. *J. Infect. Dis.*, 1913, xii, 386.

By Surg., Gynec. & Obst.

The hæmolytic growth on blood agar, capsule formation, solubility in bile, sugar reactions, pathogenic properties in animals and anaphylactic reactions are considered in discussing the relationship existing between various members of the streptococcus group. These various properties indicate that a gradual transition occurs from one member of the group to another, and it is difficult or impossible to clearly define the sub-groups. Experiments are cited pointing definitely to a transformation of one member into another. This phenomenon undoubtedly takes place within certain limits, and appears to be not uncommon.

SURGICAL THERAPEUTICS

Wolf: The Action of Collargol Enemata in Septic Processes (Über die Wirksamkeit von Kollargolklysmen bei septischen Prozessen). *Deutsche med. Wchnschr.*, 1913, xxxix, 944.

By Zentralbl. f. d. ges. Chir. u. i. Grenzgeb.

As the intravenous injection of collargol is accompanied with considerable difficulty the author injected a 6 per cent solution (50 cc.) per rectum. The first patient for whom he used it was a soldier with a definite sepsis. Intravenous infusions of salt solution, 4 L. daily, three times with 1 gm. antipyrin added, did not affect the condition at all; neither did the subcutaneous injection of iodipin in 25 per cent solution. Later 25 cc. of a 2 per cent solution given intravenously according to Kausch also proved ineffectual and resulted in a thrombosis of the basilic vein. Thereupon 50 cc. of a 6 per cent solution of collargol was given per rectum every fifth day and the desired effect was obtained. Temperature dropped until complete recovery resulted. A total of eight such injections were given. These injections caused absolutely no mucous membrane irritation or other unpleasant symptoms.

WEICHERT.

Mokrzecki: The Treatment of Anthrax with Salvarsan (Zur Salvarsanbehandlung des Milzbrand). *München. med. Wchnschr.*, 1913, lx, 1089.

By Zentralbl. f. d. ges. Chir. u. i. Grenzgeb.

The patient had a severe malignant pustule on the neck with definite constitutional symptoms. The author cauterized the pustule and then administered .6 gm. salvarsan intravenously. The local and general symptoms receded rapidly, the temperature becoming normal within twenty-four hours. He attributes the result obtained to the salvarsan infusion.

HAGEMANN.

ELECTROLOGY

Snow: Dosage Measurements and Control of the X-Ray and Other Agents in Therapeutics. *Internat. J. Surg.*, 1913, xxvi, 199.

By Surg., Gynec. & Obst.

In considering dosage as applied to X-rays it must be admitted that none of the factors involved can be constant, the vacuum of the tube, the intensity of the rays or the resistance of the receiver, the patient. Many mechanical devices have been invented to test the penetrating powers of the rays but as a general rule the safest method to follow is to depend upon the results obtained to govern the subsequent dosage. As a rule, the current should be passed through a milliamperemeter on its way to the tube. A current of one milliampere may be allowed to flow through a tube at a distance of 12 to 14 inches from the surface to be irradiated for a period of ten minutes with safety. This treatment may be repeated on alternate days. Where the condition is a malignant one a longer exposure may be advisable. An accessory treatment can be secured from the use of the high-frequency current. This current has been shown experimentally to inhibit the action of the X-rays upon the skin and to prevent a dermatitis. The use of the two rays together is especially indicated in the treatment of many of the conditions due to the pyogenic organisms.

J. H. SKILES.

Dessauer: Physical and Technical Principles of Deeply Penetrating X-Ray Treatment (Physikalische und technische Grundlagen der Tiefenbestrahlung). *Deutsche Gesellsch. f. Gynäk.*, Halle, 1913, May.

By Zentralbl. f. d. ges. Gynäk. u. Geburtsh. s. d. Grenzgeb.

The author by a series of experiments demonstrated that the formation of the so-called hard or penetrating rays is dependent not only on the tube, but also upon the manner in which it is operated. The currents led into a tube will use up that tube equally, but the number of hard rays produced will vary under different conditions. It is of no advantage to increase the current through a tube beyond normal values; the important point is to operate the tube in such a manner that the largest number of hard rays result. This can be accomplished in the following manner: (1) By using a not too high

frequency (twenty to twenty-five cycles per second), as then the ionization of the tube does not occur between the last two cycles. (2) The proportion of penetrating rays is increased if the current density in the tube during each cycle is comparatively large. It is recommended, therefore, to start with a sufficiently high primary voltage to make the current density correspondingly high. (3) He has determined by means of spectrum analysis that the greater number of hard rays are produced at or near the anode and the so-called softer or less penetrating rays near the cathode. He therefore constructed an apparatus for deep penetrating rays, taking advantage of these three points, and in particular utilizing only the rays at the beginning of each illumination.

Bucky: A Grating-Diaphragm to Cut off Secondary Rays from the Object. *Arch. Rönt. Ray*, 1913, xviii, 6. By Surg., Gynec. & Obst.

To eliminate the so-called object secondary rays, which are really secondaries arising within the tissue and projecting in all directions to blur the object shadows cast by the primary cone of rays, a metallic grating is placed between the object and the plate.

This grating is composed of numerous strips of metal two to four centimeters wide arranged cross-wise on edge. The grating alone has the drawback of casting a gridiron-like shadow on the plate. When used in skiagraphy of an anatomic part each mesh of the grating acts as a square diaphragm absorbing all except the direct rays from the anode. In this way practically all "diffusion effects" are eliminated. Other things being equal, the length of exposure must be increased about 25 per cent when using the grating.

HOLLIS E. POTTER.

Werner: The Radio-Therapy of Tumors (Die Radiotherapie der Geschwülste). *Strahlentherapie*, Berl., 1913, ii, 614. By Zentralbl. f. d. ges. Chir. u. i. Grenzgeb.

Werner reports his experiences with 3,500 patients with tumors whom he treated during six years and a half. After a detailed consideration of the results and the limitations of the X-ray therapy, he discusses the combined method of treatment with radium, mesothorium and thorium, the results of which are rather good and are expected to be successful in the future.

The combined radio-therapy consists of: 1. A diffuse, relatively homogeneous, concentric X-ray radiation, which should embrace the entire focus of the disease and the neighboring organs. 2. A local external and internal radiation with radio-active substances by application of radiating bodies and pastes as well as the injections of radio-active emulsions and solutions with cholin salt solutions. 3. Intravenous injections of radio-active solutions, especially of thorium-X, and of intravenous and intraglutal injections of cholin salt solutions. THIEMANN.

MILITARY AND NAVAL SURGERY

Lotsch: Gunshot Injuries of Blood Vessels (Schussverletzungen der Blutgefäße). *Deutscher chir. Kong.*, 1913.

By Zentralbl. f. d. ges. Chir. u. i. Grenzgeb.

The author speaks of his personal experiences obtained in the Balkan war, and comes to the following conclusions: The modern pointed bullet frequently causes blood-vessel injuries. Excepting the severe fatal hæmorrhages from large vessels, there are relatively few primary hæmorrhages that need immediate operative interference, because the entrance and exit wounds of the modern bullet are very small. All types of blood vessel injury are seen, from erosions to clean perforations and complete severing of vessels. The artery and vein are very frequently injured together. Usually a quiet hæmatoma develops, which in a few days begins to pulsate, and becomes a spurious aneurism. All injuries in the neighborhood of large vessels without large hæmatomas may develop mural thrombi in the vessels and should be treated to prevent embolism. Cases with quiet hæmatomas, if well mobilized, may be transported to the field hospital under good transportation. The dangerous hæmorrhages can be observed at the little wound plugs. Only in threatening rupture, in danger of pressure, gangrene, and suppuration, should primary ligation be done. With proper fixation and, if necessary, compression, most gunshot injuries of blood-vessels will heal without operation. Under the primitive conditions of troops and field hospitals, ligation of vessels is difficult and time consuming. Unnecessary ligations are to be avoided and should be left to retrogressive healing. Hæmorrhage in all cases demands immediate interference in narcosis and with a compression anæmia. Double ligation proximal and distal to the injury should be practiced. Under unfavorable conditions this is difficult for the trained man, impossible for the inexperienced.

The technique of blood vessel ligation is of considerable practical importance for emergency surgery on the battlefield. The ligation of blood vessels ought to be practiced more than ever in courses of operative surgery. In late hæmorrhages after four to nine days, the collateral circulation may be relied upon, at least in the extremities. Aneurisms are first treated by compression. The above-mentioned conditions may, however, demand operation at any time. Aneurism operations should be attempted only in permanent hospitals, where extirpation after double ligation may be performed under ideal conditions. Suture of blood vessels is only possible in a very small number of cases, and then it should be done under the best possible conditions. Primary suture of vessels should not be attempted in field hospitals.

GYNECOLOGY

UTERUS

Romeo: A Large Coprolith Enclosing the Uterus and Simulating a Malignant Tumor (D'un voluminoso calcolo fecale inglobante l'utero e simulante neoplasia). *Gazz. d. osp. e d. clin.*, Milano, 1913, xxxiv, 536.

By Zentralbl. f. d. ges. Gynäk. u. Geburtsh. s. d. Grenzgeb.

The patient was a woman 32 years of age, suffering from a dyspepsia for the past three years, increasing anæmia, loss of weight (20 kg.). Lately she had burning and pressure over the colon with tenesmus and frequent but small bowel movements consisting of bloody fluid. Numerous diagnoses were made: endometritis, ovarian cyst, inoperable carcinoma of the rectum, etc. The patient was almost cachectic; the small pelvis was filled with a hard tumor nearly the size of a child's head. Uterus was palpable only anteriorly; at its sides and posteriorly it was continued into the tumor. The mass could be palpated from below through the rectum with pressure exerted from above. It was with difficulty removed. The mass weighed 550 grs. and consisted of foul-smelling extremely hard faeces. The rectum was tamponed on account of hæmorrhage. The next day the uterus was easily palpated, and suppuration of the posterior wall of the vagina occurred. The patient gained in weight rapidly, and a complete recovery ensued.

The author emphasizes the importance of examining the rectum in all cases of pelvic disease. He also recommends the prophylaxis of chronic obstipation, a frequent accompaniment, and occasionally the etiologic factor, of pelvic disease. COLOMBINO.

Wilson: Chorio-Epithelioma Following Hydatidiform Mole and Giving Rise to Intra-peritoneal Hæmorrhage from an Extension in the Right Meso-salpinx. *Proc. Roy. Soc. Med.*, 1913, vi, Obst. & Gynec. Sect., 224.

By Surg., Gynec. & Obst.

Wilson's case is that of a woman 30 years old, married 3 years and the mother of one child 21 months old. She suffered from mammary abscesses and cystitis for three months following her delivery. The menstrual periods had been regular until 3 months before examination, when she became pregnant and went on normally for 2 months. At that time she was seized with bleeding which has continued up to the time of the examination. She has had some vomiting and cramplike abdominal pains. The uterus on examination was large and fairly firm. On curettage a hydatid mole the size of the closed fist was found. The patient recovered nicely. At the end of four weeks she complained of an irritable bladder, some pain and heaviness in the pelvis along with a little blood-stained daily vaginal

discharge. Four weeks later on abdominal section free red blood was found in the peritoneal cavity, with a large, dark clot behind the uterus. The uterus and both appendages were removed and the patient was discharged convalescent three weeks later.

In the right fundus of the uterus there was a rounded projection, encapsulated, dark red in color, friable and presenting the typical appearance of chorio-epithelioma. This growth projected as a small, polypoid, sessile mass into the cavum uteri; elsewhere the endometrium was normal in appearance. The tubes and ovaries were healthy, but on the posterior surface of the left meso-salpinx a small eroded nodule was discovered from which the free blood in the peritoneal cavity was coming. This also was of the same character as the fundal tumor, and as no evidence of a continuity of growth could be demonstrated it was doubtless of embolic origin.

C. D. HOLMES.

Raspini: Adenomyositis of the Uterus and of the Rectum (Sull'adenomyositis dell'utero e del retto). *Ginecologia*, 1913, ix, 577.

By Zentralbl. f. d. ges. Gynäk. u. Geburtsh. s. d. Grenzgeb.

After a general résumé of the present status of adenomyositis the following clinical history is detailed: A female patient, 36 years old, had had one abortion, followed by severe pains in the lower abdomen, but was otherwise generally healthy. Between the uterus and rectum an immovable tumor was palpated, but the adnexa and rectum were normal. This led to the diagnosis of malignant tumor in the recto-vaginal space. The uterus was extirpated with the tumor. Analysis showed that there were numerous hollow spaces lined by cylindrical epithelium. As far as the etiology is concerned, the author assumes that the whole process was probably the result of an inflammatory activity and irritation. The possibility of its origin from Müller's ducts cannot be denied. The author believes that cases are not infrequent, which, if microscopical examinations of inflammatory processes of the pelvic peritoneum were made, would reveal more frequently the picture of adenomyositis. The most certain treatment is operative removal.

FLATAU.

Daels: Contribution to the Study of Benign Chorio-Epitheliomas of the Wall of the Uterus and Tubes (Contribution à l'étude de chorio-épithélioma bénigne dans la paroi de l'utérus et des trompes). *Bull. de l'Acad. roy. de méd. de Belg.*, 1913, xxvii, 175.

By Journal de Chirurgie.

The author states that Schikele of Strasbourg, has shown that there is a hyalin degeneration in the

vessel walls of the uterus during pregnancy. This sign of pregnancy which appears first during the first month is of great importance as it disappears last following abortions. Daels and Doussy state that there exist in the uterine vessel walls syncytial cells rich in chromatin, more or less regularly arranged which differ from the decidual cells.

In two cases of tubal pregnancy which had been resorbed several months previously, the author found such elements in the wall of the tube. This contradicts Meyer's statement that normal exochorial involution occurs two weeks after the expulsion of the foetus. The clinical importance of these cells is that they serve to differentiate between the endometritis following abortions and other forms. In the treatment of that following abortions in which syncytial cells were found by curettage, 83.3 per cent were successful, 12.5 per cent better and 4 per cent unsuccessful. In the other endometritis cases treated by curettage there were 31.2 per cent successful, 43.7 per cent improved and 24.9 per cent unsuccessful. The author thinks that all the simple endometritis cases following interruption of pregnancy are curable by curettage.

These syncytial cells do not seem to have any connection with the nourishment of the foetus nor with utilization of maternal waste products. It seems that these aberrant cells have lost their normal function and are in fact benign neoplasms which the organism is able to combat successfully. Daels believes that a microscopical examination of the walls of the tube or uterus would serve to substantiate a diagnosis of pregnancy by Abderhalden's serum test.

J. DUMONT.

Bumm: Results of X-Ray and Mesothorium Treatment of Uterine Carcinoma (Über die Erfolge der Röntgen- und Mesothoriumbehandlung beim Uteruscarcinom). *Deutsche Gesellschaft. f. Gynäk.*, Halle, 1913, May. By Surg., Gynec. & Obst.

Skin epithelioma have long been cured by radium. The use of hard filtered rays and large quantities of radio-active substances makes the deep seated and more rapidly growing tumors subject to treatment, 10,000 x Kienbock and 15,000 milligram hours and even more have been given. He reports 12 cases:

1. Squamous cell carcinoma of the portio; 1,927 x. Cure.

2. Cervix cancer, a foul infiltrating tumor; 8,200 x and 12,000 milligram hours mesothorium. Only scar tissue left; the curette brought nothing away.

3. Carcinoma of the vagina with involvement of the rectum 3,500 x and 8,700 milligram hours mesothorium; scar tissue where carcinoma was; no secretion or hæmorrhage.

4. Carcinoma of vagina; 3,400 x and 14,200 mg. hours; clinically cured.

5. Carcinoma of the cervix; 10,000 x and 15,120 mg. hours. Callous scar with no secretion.

6. Carcinoma of the cervix; 1,900 x and 10,400 mg. hours; curette showed nothing..

7. Stinking carcinoma colli; 9,350 mg. hours; ectropion covered with epithelium; operated upon.

8. Large crater-like carcinoma colli; in 24 days 13,320 mg. hours; crater closed; operated.

9. Large squamous-cell carcinoma involving urethra and neck of bladder; 1,900 x; complete cure.

10. Adenocarcinoma of the urethra; 800 x and 4,600 mg. hours; reduced to a small ulcer in the urethra; still under treatment.

11. Recurrence after total extirpation; large ulcer with infiltration; exposure aided by incision; 3,500 x and 14,200 mg. hours; complete overgrowth of skin; formation of a scar cavity.

12. Recurrence after total extirpation and secondary recurrence operation; large foul tumor filling the vagina; 1,218 x and 15,350 mg. hours. Scar tissue, curette shows no cancer.

All parts of the cancer that can be reached are destroyed and the part is clean in a few weeks, with or without extensive scar tissue. Cases 7 and 8 showed cancer still present, but they had been treated only 9 and 21 days respectively. To avoid ulceration, very hard rays must be used. Bumm used lead filters. He found two cases which were cured of their cancer but died of necrosis and urinary infections.

JAMES R. MILLER.

Döderlein: Röntgen-Ray and Mesothorium Treatment of Myoma and Carcinoma of the Uterus (Röntgen-Mesothoriumbehandlung bei Myom und Carcinom des Uterus). *Deutsche Gesellschaft. f. Gynäk.*, Halle, 1913, May. By Surg., Gynec. & Obst.

The author ascribes to Krönig and his school the credit for the great advance in the radiotherapy of cancer as well as of myoma. Döderlein has been working along similar lines and reports exceedingly good results from the use of mesothorium in cancer. The cancer of old people is easiest to influence. One operable case in a very early stage was treated with complete cure; a heart lesion made operation very unsafe. Döderlein presents beautiful microscopical preparations, which prove that his optimism has a firm foundation. The cancer cells are shown to disintegrate at different stages in the treatment, whereas the normal cervical mucosa remains in apparently perfect condition. A selective action of the highly filtered rays for the cancer cells is therefore proven.

J. R. MILLER.

Küstner: A Peculiarly Shaped Myomatous Uterus (Ein myomatöser Uterus eigentümlicher Konfiguration). *Deutsche Gesellschaft. f. Gynäk.*, Halle, 1913, May.

By Zentralbl. f. d. ges. Gynäk. u. Geburtsh. s. d. Grenzgeb.

The uterus had acquired the size of an adult's head, the whole corpus being evenly transformed into a myomatous mass of tissue. The only portion still normal was the outermost layer directly below the peritoneum. This was about $\frac{1}{2}$ cm. thick and the mass consisted of a great number of myomatous nodules. This is the first case of this sort observed by Küstner, in spite of the fact that he has seen

many hundreds of myomata. The little mucosa that was present showed a normal structure. The appendages also were normal except for the peculiar smoothness on the surface of the ovary, there being no Graffian follicles and very few corpora albicantia. The hymen was absent and a penis-like protuberance projected from the external genitalia. The urethral opening was invisible and there was no vaginal pouch in the rear of this. The patient was thirty-seven years old, had never menstruated and came into the clinic on account of hæmorrhage from the genitals, the result of trauma.

SAUER.

Freund: Partial Myoma Operations (Über partielle Myomoperationen). *Deutsche Gesellsch. f. Gynäk.*, Halle, 1913, May.

By Zentralbl. f. d. ges. Gynäk. u. Geburtsh. s. d. Grenzgeb.

In women approaching the menopause it is frequently possible to retain menstruation by performing a partial operation, which however will be radical in effect. This is an advantage over X-ray therapy. The author reports a new wedge-shaped myomectomy including the entire fundus and corpus uteri. The bladder is stripped off the uterus; the curved incision extends from the middle of the posterior uterine wall, passes the tubal insertion to the middle of the anterior wall, a corresponding incision on the opposite side is made and a wedge-shaped portion is excised, including all hypertrophied mucous membrane. The defect is sutured in two layers. No myomatous nodules are overlooked by this method and large portions of hypertrophied muscle and mucosa can be removed.

In pure fundus tumors the author excises the entire fundus by means of a circular incision. Menstruation was retained in all cases and became normal. In smaller tumors both operations can be performed vaginally.

Whitehouse: Pathology and Treatment of Uterine Hæmorrhage. *Practitioner*, Lond., 1913, xc, 952.

By Surg., Gynec. & Obst.

Hæmorrhage due to pregnancy and abortion or to neoplasms is not here considered, the author confining his views to conditions where the diagnosis may be less typically set forth. His conclusions are:

1. No treatment of uterine hæmorrhage can be rational unless the cause is established; the empirical administration of hæmostatic drugs is frequently useless and indiscriminate curetting is dangerous.

2. The menorrhagia that occurs in young girls at the age of puberty is probably due to the association of functionally mature ovaries with a deficient uterine musculature. It tends to spontaneous cure and should be treated by rest and, if possible, removal to a higher altitude.

3. Hæmorrhage in young women may be due to mucous polypus, adenomatosis uteri, or bacterial infections of the uterus.

4. A practical method of investigating the bacteriology of the uterus is by the collection of the menstrual blood.

5. Hæmorrhages at the menopause are frequently the result of increased arterial tension, portal obstruction or degeneration and fibrosis of the uterus secondary to arteriosclerosis. It is probable that some cases of fibrosis uteri are syphilitic in origin. Treatment must be to reduce vascular tension. Ergot usually fails and it may be necessary to remove the uterus.

6. Faults in the calcium metabolism may be the cause of obscure uterine bleeding, which may be cured by discovery of the cause and the administration of calcium salts. Occasionally, the combination of thyroid tissue with calcium is beneficial.

7. In every case of uterine hæmorrhage, it is essential to look for a general cause before the local pelvic condition is investigated.

CAREY CULBERTSON.

Sehrt: The Thyreogenous Etiology of Hæmorrhagic Metropathies (Zur thyreogenen Ätiologie der hæmorrhagischen Metropathien). *München. med. Wchnschr.*, 1913, lx, 961.

By Zentralbl. f. d. ges. Gynäk. u. Geburtsh. s. d. Grenzgeb.

Sehrt investigated twenty cases of uncomplicated metropathies, finding a high grade lymphocytosis (50%) and a relative neutrophile leucopenia (45-68%) in thirteen. One case, which had no lymphocytosis, presented 10.2% eosinophiles. Coagulation of the blood was increased in 19 cases (8-4 minutes against 9-10 minutes normally). From the analogous blood picture in hyperthyroidism he concludes that the disturbance of the relation between the thyroid and ovary may be the basis for these unexplainable hæmorrhages and that many cases of hæmorrhagic metropathy are really abortive cases of myxœdema. On account of the parallelism of the symptoms of tetany of pregnancy and eclampsia and because of the absence of a definite anatomical basis by which these two conditions can be differentiated clearly, the author advises noting the blood picture of eclampsia. The histological findings of Hofmeister, who observed kidney changes after thyroidectomy, the combination of myxœdema and eclampsia (Herrgott, Fruhinsholz, Jeandelize), the increased coagulability of the blood in eclampsia (Jarzew) lead to the suspicion that a relation exists between hypo-thyroidism and eclampsia. This view is supported by an observation of the author's. The patient was a woman who had had a difficult labor with severe hæmorrhages three years previously, and who presented the blood picture of hypo-thyroidism. The labor occurred spontaneously, but a four-day eclampsia developed.

KÖHLER.

Bell: The Pathology of Uterine Casts Passed During Menstruation. *Surg., Gynec. & Obst.*, 1913, xvi, 651.

By Surg., Gynec. & Obst.

This paper is based on some original pathological investigations of uterine casts passed during menstruation. The author states that there are two distinct kinds of uterine casts: (1) True blood casts

of the uterus, (2) endometrial casts. He considers that the blood casts are formed by the clotting of menstrual blood within the uterine cavity. He points out that he has already shown that menstrual blood does not clot normally owing to the extraction of the fibrin ferment by the endometrium, but that when there is menorrhagia the flow is too rapid for this retraction to be effected and consequently the blood may clot either in the uterus when blood casts are formed, or in the vagina. The endometrial casts may be either thick or thin according to the depth of the denudation of endometrium which is brought about by the hæmorrhage which strips up either the whole or the superficial layers of the endometrium. The latter in these circumstances, is denser than normal owing to the decidua-like change in the cells of the stroma.

Illustrations are given of many menstrual endometrial casts to show the macroscopical and microscopical appearances. One case is of peculiar interest, for the author removed the fallopian tubes three years previously. Almost every month this patient passes a thick endometrial cast, which resembles in macroscopical appearance an early abortion. Microscopically the cells of the stroma show a marked decidua-like reaction.

Chisholm: Menstrual Molimina; Adult Cases.
J. Obst. & Gynec. Brit. Emp., 1913, xxiii, 389.

By Surg., Gynec. & Obst.

Basing her conclusions on a study of 100 cases, and upon the previous work by Tobler and Ketsham, the author has formulated the following:

1. Among adults the causes of disturbance at the menstrual period are many more than among adolescents.

2. Passive hyperæmia of the pelvic organs appears to be the cause of much local pain. This is relieved in the majority of cases in the first day after onset of menstruation.

3. Unhealthy hygienic conditions and mode of living contribute to lowering the general nervous system so that pain is readily felt and a habit of pain at the menstrual period formed.

4. Nervous symptoms, reflex and vasomotor, are often associated with secondary menstrual discomfort.

5. Except in a very small minority of cases this menstrual discomfort does not affect the woman's capacity for carrying on her ordinary work.

6. Any appearance or development of menstrual pain shows a pathological condition whose cause, whether local or general, ought to be investigated and treated before the discomfort becomes established as a regular habit. CAREY CULBERTSON.

Haymann: Disturbed Menstruation in Psychosis (Menstruationsstörungen bei Psychosen). *Ztschr. f. d. ges. Neurol. u. Psychiatr.*, 1913, xv, 511.

By Zentralbl. f. d. ges. Gynäk. u. Geburtsh. s. d. Grenzgeb.

The author made a careful study of cessatio mensium in the psychic cases. The patients

ranged from 18 to 46 years and included only those who failed to reveal a cause for the menstrual disturbance. All cases had been observed at least 3 months. The author's observations were made on 206 such patients and his conclusions are:

1. Cessatio mensium is frequently met with.

2. It may begin in any stage of the mental disturbance. It precedes the psychic symptoms in a small percentage of cases but occurs most frequently one to two months after the mental symptoms become manifest.

3. Menstrual disturbance seems to be absent in cases of chronic paranoia, is rare in imbeciles, in cases of hysterical psychoses, and degenerative idiocy. It is present in 50 per cent of epileptics and 33 per cent of the cases of mania and melancholia. It is most manifest in cases of dementia præcox and catatony, somewhat less in hebephrenia and least of all in dementia paranoides. It is very frequently present in organic psychoses, including paralysis.

5. There is a decrease in weight at the time of menstrual disturbance, the weight again going up when the menses return. KÖHLER.

Blau: Dysmenorrhœa and Its Treatment (Wesen und Behandlung der Dysmenorrhœe). *Med. Klin.*, 1913, ix, 653.

By Zentralbl. f. d. ges. Gynäk. u. Geburtsh. s. d. Grenzgeb.

The majority of authors are agreed that the cause of the pains lies in the condition of the nervous system. In most cases the weakness of the nervous system is associated with a hypoplasia of the genitals and, like the latter, must be considered as a part of a constitutional anomaly of asthenic infantilism. It is therefore necessary to test the general condition of the patient and especially the nervous system and look for symptoms of asthenic infantilism.

In addition to the general treatment psychotherapy alone is the etiologically correct one. Regulation of the bowels is of extreme importance. Sexual intercourse is advised when no unfavorable influence upon the nervous system is feared. Locally hydrotherapy, gymnastics and massage are recommended in sexual infantilism. If the general and local treatment fail, sounding and dilatation of the uterus may be employed. Castration is of questionable value. X-ray treatment is dangerous because of the possibility of inducing permanent sterility or, later, feeble conception products. Pain incident to menstruation should be controlled by hot applications and the usual drugs. Nasal therapy on account of its good results deserves to be tried in each case. BISCHOFF.

Zoeppritz: The Treatment of Amenorrhœa (Zur Behandlung der Amenorrhœe). *Deutsche Gesellsch. f. Gynäk.*, Halle, 1913, May.

By Zentralbl. f. d. ges. Gynäk. u. Geburtsh. s. d. Grenzgeb.

In women suffering from amenorrhœa an increase in the lipid content of the blood has been observed indicating a hypo-function of the ovaries (Neumann-

Herrmann). The author investigated this fact and determined that in 25 cases of amenorrhœa a decreased amount of lipoid was found, while in another 100 cases the amount was increased. In the latter a marked improvement was obtained by the administration of ovarian extracts, while the former class did not react to ovarian preparations nor to pituitrin as recommended by Fromme.

Hill: A Further Consideration of the Use of Corpora Lutea in the Treatment of Artificial Menopause. *Surg., Gynec. & Obst.*, 1913, xvi, 712.
By Surg., Gynec. & Obst.

Hill, in reporting twelve cases treated with corpora lutea, was careful to select patients of intelligence and reliability, running from 25 to 38 years of age, cases upon whom he had operated and removed both ovaries and who showed the most severe type of nervous symptoms. Following the use of corpora lutea in these cases the nervous manifestations were completely relieved in every case. In two only was there complete relief from flashes of heat. In one case where insomnia was a most disturbing symptom, complete relief was obtained from corpora lutea, five grain capsules being used three times daily (total number, 50). The author was unable to report any cures, as in several instances the treatment was interrupted and in others who had ceased treatment, relapses occurred and they were compelled to resume treatment.

Hill in a later article calls attention to cases of artificial menopause reported to in which partial or complete failure to control symptoms were noted following the administration of corpora lutea. In seeking to determine why these reports were so much at variance with his own results, it developed that insufficient medication was the prime factor in the failure to control symptoms. In some cases as few as twenty-four capsules were given; in others the maximum was one hundred. Hill calls attention to the abrupt precipitation of symptoms and the great amount of disturbance, etc., and the obvious necessity for a treatment of some duration. The disturbing symptoms usually appear within a short time after operation, in many cases showing at the time the next period should manifest itself and continuing, unless relief is obtained, for from eighteen months to three years.

Symptoms may disappear after using corpora lutea and reappear after its administration has been discontinued. Treatment should be continued for some weeks after the patient presents a normal condition. The author finds it necessary in most of his cases to give at least one hundred capsules and in others two hundred before suspending treatment. In relapsing cases the second treatment is usually much shorter than the first.

Ward: The Treatment of Endometritis. *N. Y. M. J.*, 1913, xcvi, 1181. By Surg., Gynec. & Obst.

The pathology and treatment of endometritis are discussed in this paper. Ward refers to the revolu-

tionizing work of Hitschmann and Adler, published in 1908, on the cycle of the four distinct stages of the endometrium throughout the menstrual month. The first stage is the premenstrual, which begins six to seven days prior to the appearance of the flow and is characterized by an increase in the thickness of the mucosa two to three times that of the resting stage. The glands and their cells are enlarged and the stroma throughout has assumed a decidual type. This stage presents the conditions which were previously considered as characteristic of chronic hypertrophic endometritis. The second stage in the cycle is the menstrual stage, when the blood appears and a general deturgescence is noted. The glands become flattened and some of the superficial epithelium is cast off. The third or post-menstrual stage shows the mucosa thin and pale. The glands are narrow, straight, with contracted lumina, and the epithelial cells are small. The fourth stage is the interval stage which lasts about two weeks and shows the mucosa in what we have hitherto considered the normal condition. The normal changes, therefore, must be recognized as a temporary physiological hyperplasia and they become pathological when they are permanent or stationary. The permanent hyperplasia may be due to true inflammation or to circulatory disturbances.

Albrecht and Logothetopoulos contribute the following conclusions for an anatomic diagnosis of endometritis: 1. It is based on certain changes in the stroma and blood vessels, circumscribed or diffuse infiltration of leucocytes, exudation, hypertrophy or atrophy of the stroma, the presence of blood pigments, proliferating blood vessels and infiltration along the vessels, and inflammatory infiltration in the muscular interstices. 2. In addition to the normal premenstrual hyperplasia there are certain pathological forms which are stationary; as the transitional forms between hyperplasia and adenoma occurring during the menopause, post-menstrual and interval hyperplasia; hyperplasia following prolonged placental retention; and hyperplasia after prolonged hæmorrhages. 3. The permanent hyperplasia may be distinguished from the temporary form by certain anatomical features: mitosis, which is not marked in the latter form; irregularity, as absence of the premenstrual folding of the mucosa; true intraglandular papillary proliferation; twisting and elongation of the glands; thickening and increasing of the epithelium due to mitosis; irregular secretion and loss of the typical premenstrual secretion. 4. In chronic inflammation the regularity of the cyclical menstrual phase is disturbed. 5. Chronic inflammation usually causes a proliferation of the uterine glands; hyperplastic and proliferating endometritis is therefore a correct term, but it should be distinguished from the pathologic hyperplasia of the uterine mucosa in the absence of inflammation.

The treatment of endometritis is presented from the clinical rather than pathological standpoint. All cases of endometritis are divided into two

varieties: one, those which are the result of an infection; and two, those resulting from circulatory disturbances. In the first variety, acute and chronic types are seen, but the chronic form, on account of the loss of virulence of the causative bacteria, or their disappearance, simulates closely the non-infective type. The treatment is summarized as follows:

1. Leucorrhœa, the most prominent manifestation of the disease, comes from the uterine cavity and not from the vagina.
2. The treatment to be observed in acute infective cases is masterly inactivity.
3. The first and most important principle to be observed in treating cases of chronic hyperplastic endometritis is to determine the cause of the venous stasis and treat the same by appropriate measures.
4. The curette is the most valuable means for removing the greatly thickened and diseased endometrium, but if it is used alone, without correcting the cause, only temporary relief is obtained.
5. Vaginal douches, glycerine packs, and postural methods, if employed properly, are valuable adjuncts in aiding and improving the pelvic circulation.
6. In those cases which are probably dependent upon disturbed ovarian function, either excessive or diminished, such as in the preclimacteric menorrhagias and metrorrhagias, arteriosclerotic uteri, chronic metritis, fibrosis, etc., and which are not benefited by the curette or local measures, a cure is sought in the direction of ovarian control, possibly by the X-ray or by sera from antagonistic glands of internal secretion; otherwise complete ablation of the ovaries or hysterectomy is the only resort.
7. In submitting curetted tissues to the pathologist it is imperative that the relation of the time of the curetting to the time of menstruation be stated, in order to obtain an opinion of value.

HENRY SCHMITZ.

Jones: Inversion of the Uterus, with a Report of a Case Occurring During the Puerperium and Caused by a Fibroid. *Surg., Gynec. & Obst.*, 1913, xvi, 632.
By Surg., Gynec. & Obst.

Inversion of the uterus is a very rare pathological condition and usually is caused by child-birth. It occurs once in about 128,000 obstetrical cases. Not only did the author's case develop a comparatively short time after labor, but it had in addition a fibro-myoma as a causative factor. Tumors of the uterus produce only about 13 per cent of the inversions, and when present are usually the sole cause, entirely independent of pregnancy. An extensive review of the literature in connection with this case leads to the following conclusions:

1. Etiology. In obstetrical inversion, the primary cause is uterine relaxation. The chief secondary factors are pressure on the fundus and traction on the cord. In inversion not obstetrical in origin, uterine fibroid is almost the exclusive cause.
2. Pathology. Most cases are both acute and complete; in the complete cases, the most important point is the degree of contraction of the cervix. In inversion of gynecological origin, the causative tumor is of preëminent importance.

3. Symptoms. In acute cases, the cardinal symptoms are hæmorrhage, shock and pain. Later, the manifestations of a complicating infection may appear. In chronic inversion, the symptoms are those of marked uterine prolapse plus those of menorrhagia and metrorrhagia.

4. Diagnosis. This is made from the objective findings exclusively; in obstetrical inversions it is almost always very easy. Vaginally, a large, soft, pear-shaped, bleeding tumor is found, with the placenta attached in about half of the cases. Abdominally, no corpus is found, but instead there is a cuplike depression. In gynecological cases, the diagnosis of inversion due to a fibroid frequently is very difficult. The chief points are: first, the shortening of the uterine canal produced by inversion as compared with the lengthening caused by a fibroid; and secondly, the indentation produced by the inversion on the peritoneal surface.

5. Prognosis. The mortality in acute cases in recent years has been about 35 per cent; in chronic cases, about 6 per cent.

6. Treatment. In all acute and in most chronic cases, the manual reposition should be tried. In most of the former, if undertaken early, and in many of the latter this procedure is successful. If it fails, repositors, etc., may be used, but only for a short time. If these are unsuccessful, one should resort at once to some operative method, the one of choice being colpohysterotomy. This operation stands preëminent in the treatment of difficult cases of uterine inversion on account of the facility of its performance and its success in accomplishing the reduction of the inversion, and also because of the practically complete absence of any mortality. The uterine incision should be made at first through the cervix only, and later should be extended as far into the corpus as necessary to accomplish reposition. In inversion due to tumor, the treatment is mostly that of the causative fibroid. After this is removed, if the uterus still remains, spontaneous replacement occurs, in about one third of the cases, while in the other instances reduction is accomplished usually without difficulty by non-operative methods. A case is reported in detail.

Donald and Shaw: Retroflexion of the Uterus. *Practitioner*, Lond., 1913, xc, 961.

By Surg., Gynec. & Obst.

These authors have compiled statistics with reference to symptoms commonly associated with retroflexio uteri. These symptoms are menorrhagia and metrorrhagia, dysmenorrhœa, chronic pain, miscarriage and sterility. As a result of this study they find that, in the majority of cases, these symptoms or complaints are not present in uterine retroflexion. The subsequent histories of 267 patients who were curetted for this condition have been collected. Of these 86 per cent were cured or much improved. As a result the authors argue strongly in favor of curettage alone rather than a suspension operation. Their conclusions are:

1. Simple mobile retroflexion of the uterus seldom, if ever, causes symptoms.

2. A patient with a mobile retroflexed uterus, suffering from any of the symptoms mentioned and who has not improved with a course of drugs, should have the uterus dilated and curetted.

3. Any fixation operation is unjustifiable in these cases until curettage has been given a trial.

4. If curettage has failed to improve the condition within twelve months of the operation, a fixation operation may be advised.

5. In almost all the cases in which curettage has failed, some condition other than simple retroflexion will be found.

CAREY CULBERTSON.

Andrews: An Unusual Case of Rupture of the Uterus. *Proc. Roy. Soc. Med.*, 1913, vi, Obst. & Gynec. Sect., 272. By Surg., Gynec. & Obst.

The patient was 32 years old and had had two previous instrumental deliveries. In her third labor the accoucheur had pulled the head through the brim of the pelvis with the forceps with great difficulty. The child was born alive with the occiput anterior, and the placenta was removed by hand. No anæsthetic was employed. Twenty-four hours later the patient's condition was grave. The swollen, lacerated cervix protruded three or four inches from the vagina, it being very dark in color and giving off an offensive odor. Examination showed (1) an incomplete rupture of the perineum, (2) the vagina was completely separated from the cervix except for about three inches in front and to the right side, (3) the lower uterine segment and cervix were separated from the upper segment except on the right side and in front, (4) the lower uterine segment and cervix were torn through from top to bottom on the left side. A large quantity of blood was found in the peritoneal cavity. Vaginal hysterectomy was undertaken, the greatest difficulty coming in the separation of the bladder from the cervix. The torn left uterine artery could not be found. The anterior and posterior peritoneum and the vaginal walls were sewn together, a large drainage tube was inserted and the perineum was repaired.

Recovery eventually took place after four and one-half weeks of pyrexia. Andrews believes that the accoucheur must have applied the forceps outside the uterus, the cervix and the lower uterine segment being pulled away with the head by main force.

CAREY CULBERTSON.

ADNEXAL AND PERIUTERINE CONDITIONS

Abel and McIlroy: The Arrangement and Distribution of the Nerves in Certain Mammalian Ovaries. *Proc. Roy. Soc. Med.*, 1913, vi, Obst. & Gynec. Sect., 240. By Surg., Gynec. & Obst.

The authors briefly review the literature of this subject, giving the methods of investigation and the results of the work. The latter may be briefly summarized as follows:

(1) The ovary in the cat, dog and rabbit is richly supplied with nerves which enter at the hilum.

(2) In the ovarian tissue the nerves are divided into three sets, a vascular, follicular, and an interstitial set, which all anastomose.

(3) On the course of the nerves numerous varicosities are seen, while groups of very small cells are found in connection with the interstitial set.

(4) The follicular nerves lie in the tunica intima and externa and do not pass into the membrana granulosa.

(5) The function of the ovarian nerves is primarily vasomotor.

C. D. HOLMES.

Rathe: Pseudomyxoma Peritonei with Involvement of Ovaries and Appendix (Pseudomyxoma peritonei mit Beteiligung der Ovarien und der Appendix). *Monatsschr. f. Geburtsh. u. Gynäk.*, 1913, xxxvii, 322.

By Zentralbl. f. d. ges. Gynäk. u. Geburtsh. s. d. Grenzgeb.

The patient, married and 41 years old, was first operated upon in 1901 for bilateral ovarian tumor, the left the size of an adult head, and the right the size of a fist. The left tumor ruptured during its removal and a gelatinous pseudomucinous fluid escaped. The right one was also removed and showed the same characteristics. Gelatinous fluid was found free in the abdominal cavity. An uneventful recovery ensued. The patient entered the clinic again in 1912. In the scar a mass was found the size of a hen's egg, consisting of a pseudomucinous growth in the peritoneal portion of the abdominal wall. Metastases were not found within the abdomen. The patient entered the hospital the third time seven months later. The general condition was bad, a number of tumors being palpable in the abdomen. During the operation tumors were found at the place of resection of the right ovary, in the peritoneal covering of the bladder and disseminated throughout the entire omentum. The appendix also was cystic, being 8 cm. long and 4 cm. broad. The tumors were removed as far as possible, but the patient was discharged unimproved. The author recognizes the typical course of the disease, which coincides with the investigations of Werth, Olshausen and others. The epithelium is disseminated and continues to proliferate, as determined by microscopical examinations.

In 1901 Fränkel of Hamburg proved that the disease may originate from the diseased appendix. Several analogous cases have since been described. It is remarkable that these cases always terminate favorably while those originating from ovarian disease do not. The author contradicts the statement of Meyer that pseudomucinous tumors of the ovary are secondary and that pseudomyxomata peritonei is usually derived from the appendix. JUNGHANS.

Tuffier: The Grafting of Human Ovaries (Les greffes ovariennes humaines). *J. de chir.*, 1913, x, 529. By Surg., Gynec. & Obst.

Tuffier, having demonstrated that suppression of menstruation and not loss of ovarian function is

the cause of post-operative trouble following castration, presents a study of the results obtained by preserving the menstrual function through ovarian grafts. A series of 130 cases proved that ovarian autografts alone are capable of ovulating and of maintaining the menstrual function.

The author's technique is as follows: Given a case of salpingitis in which the uterus can be conserved, the tubes and ovaries are removed. The ovaries are immediately grafted in the loose subperitoneal cellular tissue, one on each side of, and 5 or 6 cm. distant from, the median incision, which is then closed in three layers. Even if the ovary be "sclerocystic" it is valuable for grafting if it be aseptic. The author strives to place the hilum of the gland next the aponeurosis.

Of 44 patients operated upon in this manner, the author has seen 19, 18 of whom have menstruated, 14 having been followed for more than 11 months. All have had the following sequence in ovulation and menstruation: Increase in volume of one ovary, then, 3 to 10 days later, menstruation with disappearance of the ovarian tumefaction. This phenomenon is not witnessed until from 3 to 7 months after the operation. The vitality of the ovarian grafts has been demonstrated in two cases which required the removal of the grafted ovary. Voluminous arteries and veins were demonstrated at the periphery of the grafts.

The author has observed that from the date of operation until the reappearance of menstruation the patients suffer from the usual effects of castration before the menopause even if the transplanted ovaries undergo their characteristic swelling. As soon as menstruation sets in, all the accidents consequent upon castration disappear. The obvious conclusion is that menstruation and not ovulation is the more important for physiological equilibrium.

These ovarian grafts do not functionate indefinitely. The distant results, from one to five and one-half years following operation, show that of 14 patients only three menstruate regularly as regards quantity and periodicity; 2 are regular but have had menorrhagia, 4 are irregular, 3 after 2 years have seen progressive disappearance of menstruation, 1 had menorrhagia with prolonged menstruation, and finally 4 had pain either at the site of the graft or in the uterus, and in 2 cases, after lapse of $3\frac{1}{2}$ years, the graft had to be removed. While in some cases the new life of the graft with normal function is shown by normal menstruation, in other cases it adapts itself badly to its abnormal nutrition and ends by atrophy.

The author finally concludes that in young women, particularly if they suffer from hyperthyroidism in the presence of inflammatory lesions requiring resection of the adnexa, the uterus should be left in place if it can be conserved, and one or both ovaries should be grafted. Thus menstruation is secured for a greater or less period of time and the physiological equilibrium of the patient is assured.

ELLIS FISCHEL.

Harms: Transplantation of Ovaries into Foreign Species; Second Report (Überpflanzung von Ovarien in eine fremde Art; Mitteilg. 2). *Arch. f. Entwicklungsmech. d. Organism*, 1913, xxxv, 748.

By Zentralbl. f. d. ges. Gynäk. u. Geburtsh. s. d. Grenzgeb.

The question considered was: Has the host of the transplanted ovary the power of influencing the germ-plasm? The ovaries of foreign species of tritons were transplanted into the domestic triton, and the two animals kept in symbiotic relationship for some days before the ovary was entirely transferred. In this way the effects of the foreign albumen was avoided. The implanted ovaries lived and produced eggs, but the offspring was that of the domestic triton. This shows that the host had no influence on the germ-plasm of the transplanted ovary.

GRÄFENBERG.

Rössle: The Effect of Castration on the Hypophysis (Über die Hypophyse nach Castration). *München. med. Wchnschr.*, 1913, lx, 952.

By Zentralbl. f. d. ges. Gynäk. u. Geburtsh. s. d. Grenzgeb.

The relations existing between the hypophysis and the genitalia are antagonistic. The experiences obtained in the study of acromegaly, dystrophia adiposo-genitalis, and the investigations after extirpation of the hypophysis all speak for that fact. On the other hand, in cases with primary changes in the genitalia more or less typical changes in the hypophysis also result, such as hypertrophy during pregnancy and the well known changes occurring in animals following castration.

The author investigated the matter on 101 hypophyseal glands. A definite enlargement of the gland by weight could not be demonstrated regularly under the conditions under which the castration had to be conducted. That in part is due to the age and the cachetic condition of the patients in whom it was necessary to extirpate the genital glands. If this extirpation occurs during the climacterium but few changes are demonstrable in the hypophysis; whereas if it occurs in younger persons the hypophysis reacts in a very short time to the removal of the ovaries or of the entire pelvic viscera and this even in the presence of severe general disease. Histologically a hyperplasia of the eosinophile cells occurs at the expense of the principal cells and especially of the basophilic cells. A special phenomenon characterizes the latter, i. e., their abundance in areas of the hypophysis in which normally but few are found.

RUNGE.

Cope and Kettle: A Case of Chorio-Epithelioma of the Fallopian Tube, Following Extra-Uterine Gestation. *Proc. Roy. Soc. Med.*, 1913, vi, Obst. & Gynec. Sect., 247.

By Surg., Gynec. & Obst.

The patient was 45 years of age and the mother of two children. Two years after the birth of her second child, which lived 17 days, she was told she had a fleshy mole. Three years after this she was seized with abdominal distress characterized by great pain, with vomiting and unconsciousness. Vaginal

examination showed an enlarged painful swelling in the left fornix. These symptoms subsided after three weeks rest in bed. One year later she came to the hospital for constipation and vomiting with a diagnosis of intestinal obstruction. On abdominal section a large mass filled the pelvis. The growth had its origin in the right side of the pelvis. There was no trace of the right fallopian tube. At the end of the third week she began to complain of pain in the right iliac fossa. She had some temperature and on opening the abdomen a second time a dark red mass was seen between the cæcum and the right brim of the true pelvis, also filling the right half of the pelvis. On removing some of the firmer portions, great difficulty was experienced in stopping the flow of blood. The patient died in a few hours.

On post-mortem examination both uterus and vagina were found to be normal, and since portions of normal ovarian tissue were found in the midst of the material removed at the first operation, and since the only traces of fallopian tube seen on that side were in the microscopic sections, there seems to be little doubt that this was a case of tubal chorio-epithelioma. The material removed at the first operation was also chorio-epitheliomatous.

From the clinical aspect the following conclusions are offered:

(1) Chorio-epithelioma of the fallopian tube has no special age of incidence.

(2) It is sometimes accompanied by a previous history suggestive of a waning vitality of the fertilized ova.

(3) The symptoms are usually those of tubal gestation followed after a period of quiescence by tumor formation and wasting. In a minority of cases uterine hæmorrhage and hypogastric pain may be all that is noticed.

(4) Sometimes a vaginal nodule first calls attention to the condition.

(5) In any suspected case abdominal section is to be advised.

(6) All tubal gestations which have been operated on should be carefully watched for a considerable period after operation.

(7) If the growth is at the angle of the uterus hysterectomy is advisable.

(8) The prognosis is unfavorable, but can never be given with certainty because recovery has taken place even when secondary deposits have formed.

(9) The origin of the tumor is from the perverted growth of the chorionic villi in a tubal mole.

EXTERNAL GENITALIA

Pozsonyi: The Surgical Treatment of Primary Carcinoma of the Vagina (As elsődleges hüvelyi rákok műtéti kezeléséről). *Budapesti orvosi ujsag, Sebeszet*, 1913, ii, 16.

By Zentralbl. f. d. ges. Gynäk. u. Geburtsh. s. d. Grenzgeb.

The author circumcises the vagina in the introitus, forms a cuff, closes the vagina and anus. Then he

makes an incision through the skin from the sacrum to the anus, removes the os coccyx and isolates the rectum on all sides. The cutaneous incision is then carried to the vagina after a circular incision is made about the anus. The muscles of the pelvic floor are cut through and the rectum and vagina are pulled down. The urethra and bladder are freed from the vagina, the ureters are pushed up, the plica vesico-uterina is cut and the uterus and adnexa are pulled down. The two spermatic arteries are ligated. The round and uterine ligaments also are tied. The latter, as well as the parametria, are then dissected. The flexure of the colon is then isolated so that the rectum may come down readily. The peritoneum is then closed, and deep retention muscle sutures are made with silk. Gauze drainage is provided for through the middle of the wound, ending near the sigmoid and peritoneum. After the wound is closed the rectum is cut through and an anus sacralis is established. Recovery was rapid and the patient was well six months after the operation. The stool is regulated by means of controlling the diet.

FRIGYESI.

Bandler: The Importance of the Inverted T-Incision in Vaginal Surgery. *Med. Rec.*, 1913, lxxxiii, 1164.

By Surg., Gynec. & Obst.

The author strongly advocates the use of the T-incision in all gynecological cases where the vaginal route is considered in operating on multipara. Such operations as the following he does with this incision: Anterior fixation, vaginal fixation, correction of cystocele, retroflexion, vaginal hysterectomy, salpingectomy, etc.

The procedure is simple. A transverse incision is made around the cervix in the anterior fornix; then the bladder is stripped off of the anterior wall of the uterus. This discloses the vesico-uterine fold of peritoneum which can be opened under guidance of the eye. The bladder is now stripped from the anterior vaginal wall and this wall is split longitudinally, beginning in the center of the transverse incision. The author claims this will make as large an opening as the average abdominal incision, and there is no danger of perforating the bladder.

EUGENE CARY.

Kurg: Esthiomene, or Lupus Vulvæ. *J. Obst. & Gynec. Brit. Emp.*, 1913, xxiii, 353.

By Surg., Gynec. & Obst.

This is an elaborate historical, pathological and clinical study, including an analysis of six cases, with three tables and then microphotographs. The author's summary is as follows:

1. Nomenclature. The term esthiomene has been misunderstood and misapplied by many authors. It should be retained as a useful term replacing the expression "hypertrophy with ulceration." It should be clearly understood that it is a tertiary syphilitic lesion. "Lupus vulvæ" should be replaced by the expression "tuberculosis of the vulva," tuberculous ulceration and hypertrophy

occurring in the perineal region, while lupus vulgaris, as found in the skin of the face, does not. Elephantiasis is a term applied to hypertrophy occurring in chronically oedematous parts whence the return of lymph has become obstructed or rendered sluggish, and where, owing to the unhealthy state of the enlarged parts, a low form of chronic inflammation has set up. The hypertrophied masses of esthiomene are not oedematous tissue enlargements; they are granulomatous growths with a tendency to necrosis.

2. The nature of esthiomene. It is not a disease *sui generis*, nor a form of low chronic ulceration occurring on a soil weakened by constitutional syphilis or tuberculosis. It is not a merely local inflammatory state following on irritation. There is no relation between it and tuberculosis. The only connection between esthiomene and malignant disease is that the former may occasionally undergo malignant degeneration. It is not due to lymph stasis; hence it does not belong to the group of hypertrophies called "elephantiasis."

3. Esthiomene is a tertiary syphilitic manifestation. (a) A direct or probable history of syphilis is almost always obtained. (b) The majority of early cases respond to antisyphilitic treatment, those later or chronic cases not so responding being no indication that esthiomene may at times be due to other causes than syphilis. (c) The chronic course of esthiomene marked by attempts at healing with subsequent relapses, the absence of local disturbances, the non-impairment of the general state of health indicate the syphilitic nature of the condition. (d) The masses of cicatricial tissue with subsequent contraction producing severe strictures and extensive deformities is typical of no other disease. (e) In no other constitutional disease is there such a constantly present combination of hypertrophy and ulceration as in syphilis. (f) The microscope reveals the typical gumma or granuloma of the third stage. (g) Up to the present time we find no cases recorded where the spirochæta pallida was found in esthiomene tissues. (h) The positive Wassermann reaction will certainly in time relegate all cases of esthiomene into the field of tertiary syphilitic lesions.

CAREY CULBERTSON.

Hazen: Perineorrhaphy with the Buried Layer Stitch. *Internat. J. Surg.*, 1913, xxvi, 214.

By Surg., Gynec. & Obst.

The author points out the objections to the old Emmet operation, especially the disadvantages of the "mass stitch" or "crown stitch." This stitch fails to bring the parts back into correct anatomical position, layer by layer, and often allows gaps to form between the deep portions. The same objections would seem to hold good here as hold in the old method of using the mass-stitch for closing the abdominal wall. Not only are the parts not approximated accurately but many times the only layers which are at all approximated are the very superficial.

With the author's method the perineum is restored

layer by layer. First the levator ani muscles are freed and brought into plain view. They are then sutured with strong chromic gut. The deep fascia is then identified and sutured in the same manner. The superficial fascia is next sutured. All of the foregoing sutures are buried. The skin is closed with some non-absorbable material.

J. H. SKILES.

Schabak: Primary and End Results of the Operative Treatment of Perineal Lacerations, Vaginal and Uterine Prolapse Through Restoration of the Pelvic Floor (Primäre und Dauerresultate bei operativer Behandlung der Darmrisse, Scheiden und Uterusprolapse durch Herstellung des Beckenbodens). *Med. Rundschau*, 1913, xl, 630.

By Zentralbl. f. d. ges. Gynäk. u. Geburtsh. s. d. Grenzgeb.

The material consisted of 516 cases. Of these there were 150 cases of perineal lacerations without any vaginal or uterine prolapse; 219 with prolapse of vaginal wall in various grades; 143 with incomplete, and 4 with complete, prolapse of the uterus. The author is of the opinion that prolapse of the vagina and uterus occurs in 90 per cent of multipara and in 3 per cent of nulipara. The degree of prolapse is directly proportional to the number of births. The disease is chronic. The first evidence manifests itself after the first birth in 45 per cent; in 6 per cent after following births; in 30 per cent after the last labor and in 19 per cent during the climacterium. In 2 per cent, the acute prolapse is due to external trauma of the perineum and is accompanied by shock. The weakness of the pelvic floor, the retroversion and the prolapse are closely associated with child-birth. A complete laceration of the perineum rarely results in prolapse of the uterus and vagina. The best results of the operative restoration of the pelvic floor are obtained by a colpoperineorrhaphy.

The longest observed case dates back eleven years, the shortest nine months. The primary operative results were: 508 complete recoveries, 3 deaths, 5 cases discharged uncured. Eight recurrences were observed among 159 patients who appeared for re-examination or answered by mail. Absolute cure therefore 94.6 per cent. Mortality rate was 0.2 per cent.

The author advises high amputation of the cervix in elongated and hypertrophied cervixes, anterior colporrhaphy in cystocele, V-shaped excision in chronic metritis and curettement in endometritis as valuable aids in restoring the pelvic floor. They add materially to the primary and end results. As in 55 per cent of the labors following the operation a laceration occurs, the author advises a perineotomy for its prevention.

KRINSKI.

MISCELLANEOUS

Hartmann: Extravesical Opening of the Ureter in Women (Über die extravesicale Ausmündung der Harnleiter bei Frauen). *Ztschr. f. gynäk. Urol.*, Leipzig, 1913, iv, 69.

By Zentralbl. f. d. ges. Gynäk. u. Geburtsh. s. d. Grenzgeb.

This patient was 49 years old and had been suffering with incontinence for 25 years. Although

she had noticed it on exertion even before that time, she alleged that a delivery when she was 24 years old was the cause of her trouble.

Examination showed that the sphincter of the bladder was intact but that there was a small opening in a bladder-like dilatation, the size of a grape, in the vulva behind and to the left of the urethral opening. The little sac emptied and filled itself rhythmically and urine came through the accessory opening. Intra-muscular injections of indigo-carmin solution demonstrated it to be a case of accessory ureter. The author performed the Stöckel operation by the vaginal route, whereby the abnormal ureter was implanted into the bladder. The result was very satisfactory.

The author then discusses the 37 cases found in the literature (13 of these being reported by the author himself). He lays stress on the dilatation of the distal end of the ureter. The only treatment is surgical. Briefly the facts of the nineteen operated cases are:

Operation	Successful	Unsuccessful
Ligation of distal end.....	1	
Intravesical ureterocystotomy.....	2	
Vaginal ureterocystotomy.....		5
Implantation		
Abdominal route.....	2	1
Extraperitoneal route.....	1	
Vaginal route.....	4	2
Resection of kidney.....	1	

Therefore the implantation method is the operation of choice. In adults, the vaginal route, and in children, the abdominal, give the best results.

DORN.

Voigts: Mesothorium as a Substitute for X-Rays
(Mesothorium als Röntgenstrahlenerersatz). *Deutsche Gesellsch. f. Gynäk.*, Halle, 1913, May.

By Zentralbl. f. d. ges. Gynäk. u. Geburtsh. s. d. Grenzgeb.

The author reports experiments conducted for the purpose of replacing the X-ray treatment of menorrhagic metropathies and fibroids with mesothorium. The preparation is enclosed in tubes 20 and 50 mg. each, which are fastened to copper rods for insertion into the uterus. Lead and silver filters were used in thickness .08 to 1 mm. Climacteric hæmorrhages were easiest to influence, nine cases being cured within a short time. The result obtained in three cases of adnexal inflammation was surprising. By excluding the menstrual congestion, the inflammation quieted down, the symptoms disappeared, and in two cases a gradual but definite decrease in the size of the tumor occurred. Seven cases of menorrhagic metritis were more obstinate, yet amenorrhœa was also obtained. Eight cases of myomata were treated with variable results. Amenorrhœa resulted three times; two cases are still under treatment, and in three cases complete failure occurred.

Among the side reactions obtained, a collapse occurred once in addition to the transient tempera-

ture rise and slight general disturbances. In three cases burns of the vagina resulted due to prolonged treatment and the use of a thin filter. In one case an exudate formed in the cul-de-sac, and in two others a severe inflammation of the rectal mucosa resulted from very intense exposures. The author considers the treatment of hæmorrhagic metropathies and menorrhagias with mesothorium as superior to the X-ray treatment. For the treatment of myomata he advises a combined method of treatment.

Fraenkel: The Action of the So-Called Gas Bacillus upon the Female Genitalia (Über die Wirkung des sogen. Gasbacillus auf den weiblichen Genitalapparat). *Klin.-therap. Wchnschr.*, 1913, xx, 485.

By Zentralbl. f. d. ges. Gynäk. u. Geburtsh. s. d. Grenzgeb.

The principal action of the gas bacillus is its invasion of the deeper lymph spaces. The development of gas separates the muscle fascicula, causing their necrosis. The author found the gas bacillus in all of the cases investigated by him, but states that other anærobic organisms may produce similar results. The prognosis in all cases of physometra is bad, even if the uterus is removed. Much more favorable are cases of tympania uteri, produced by an invasion of the amniotic cavity. A cure is effected frequently by rupture of the membranes alone. The dark bronze and blue cyanotic discoloration of the skin seen in cases of physometra was absent in the author's second case.

Serious results were observed only when bacilli entered deeper tissue spaces. Removal of placental rests suffices in the superficial infection of the inner surface of the uterus, even if bacilli enter the blood stream. The author is not certain that the small vesicles occurring in the vaginal mucous membrane of pregnant women (colpohyperplasia cystica (Winckel) or pneumatosis cystoides vaginalis) are due to the gas bacillus. He found bacilli in three cases, but had no opportunity to make cultures. The giant cell-like structures described by Chiari were also found by him in the inner wall.

WILLMANN.

Sella: Contribution to the Study of the Localization of Micro-Organisms in Experimental Septicæmia (Contributo allo studio delle localizzazioni genitali dei microorganismi nelle setticemie sperimentali). *Ann. di ostetr. e ginecol.*, 1913, xxxv, 206.

By Zentralbl. f. d. ges. Gynäk. u. Geburtsh. s. d. Grenzgeb.

The author classifies the different results of pathological and anatomical investigations of the female genitalia in women who died of acute infections, as scarlet fever, measles, typhoid, acute articular rheumatism, etc. Experimentally he injected cultures, varying in age and dilution, obtained from a carbuncle, into a vein of the ear or into the peritoneal cavity of guinea pigs. Streptococcus and staphylococcus aureus cultures were also used. All the guinea pigs died of the infection. The ovaries and the uterus were rarely the seat of abscesses; the

tubes never showed any lesions. The bacilli of the carbuncle were found in the uterus, tubes and ovaries; in the latter organs especially in the germinal zone. Staphylococci were found only exceptionally in the uterus or in the ovaries. It was never possible to obtain metastases of staphylococci in the tubes.

BERBERICH.

Kroemer: The Action of Mesothorium upon Genital Tumors (Mesothorium-Einwirkung auf genitale Neubildungen). *Deutsche Gesellschaft. f. Gynäk.*, Halle, 1913, May.

By Zentralbl. f. d. ges. Gynäk. u. Geburtsh. s. d. Grenzgeb.

Kroemer reports twenty-two cases, most of which were inoperable tumors, which he treated with mesothorium and with deep applications of the X-rays. Simultaneously the treatment was augmented with the use of Thorium X. Although the results were less satisfactory in far advanced metastatic, ovarian and intestinal cancers, nine cases of cervical cancer which were deemed inoperable improved so much that the uterus regained its movability in seven cases and a radical removal was accomplished. In one instance a radical operation could not be undertaken on account of a septic endocarditis following abortion. Similarly good results were obtained in two cases of corpus carcinoma, one with vaginal metastases; also in one case of rodent ulcer of the vulva. In the last case a spontaneous cure could have been awaited had not a coincident pruritus vulva demanded amputation. The patient was of the type in which hypersusceptibility to mesothorium exists and who consider the little capsule as a veritable "fire capsule." The extirpated inguinal glands show morbid infiltration with migratory and plasma cells, but no carcinoma cells.

In all operated cases the incision scar was treated with mesothorium for two to three hours a day during convalescence. An injury to the healthy tissues was not observed; harmless erythema and vesicle formation on the skin receded immediately with bismuth paste. The quantity of the rays administered varied. In cervix cancers the dosage was 3000-7000 mg. hours of mesothorium, augmented by several series of X-rays, which were given every ten to eleven days to 100 H. The patients at the same time were given thorium X per os in dosage of 100 e. s. E. For the local treatment thorium X (500-1000 e. s. E.) was given in the form of ointment, tampons and compresses. It was also employed in aqueous solution for hypo-

dermic injections in three cases of glandular recurrence. Aluminum and silver capsules were used as filters. The results were always controlled on the later extirpated organs and once on autopsy findings. An absolute cure of the cancer was only obtained twice. Glandular metastases were the least influenced; and of the primary tumors, those which spread toward the vagina and external surface. Deep, living carcinomatous tissue could be demonstrated in most organs.

Although the result obtained is much behind the expectations, the author nevertheless believes that the treatment with mesothorium and thorium X, supplemented with the X-rays, adds much to complete carcinoma therapy. It promises permanent cure in all external cancers of the cervix, vagina and vulva. It aids the operative therapy in so far as it improves inoperable cases; at least it does away with the sloughing and fetor. The glandular metastases have so far not been influenced favorably.

Falgowski: The Operative Treatment of Old Infiltrations (Zur operativen Behandlung alter Infiltrate). *Deutsche Gesellschaft. f. Gynäk.*, Halle, 1913, May. By Zentralbl. f. d. ges. Gynäk. u. Geburtsh. s. d. Grenzgeb.

Falgowski considers the puncturing of infiltrations through the vagina with drainage not always sufficient, as thorough drainage is not obtained or maintained long enough. Infiltrations high up are not reached, or only with difficulty. It is also impossible to secure a lasting replacement of the uterus. The author, therefore, in all chronic exudates which do not improve under conservative treatment, employs a more radical procedure. He performs an anterior and posterior colpotomy; blunt separation of the uterus from adhesions; thorough manual examination of the entire pelvis; deep vagino-fixation, and wide drainage of the entire pelvis through both colpotomy wounds. The gauze drains are saturated in 5 to 10 per cent camphorated oil. This is renewed several times.

The procedure requires from three to five weeks and the exudate disappears with the correction of the uterine position. In older women the uterus may be removed entirely. The author cured four cases in this manner. The operation is without danger, as all work can usually be done extra-peritoneally. Injuries to other organs are always prevented. The disturbances in the urinary and nervous systems are likewise favorably influenced.

OBSTETRICS

PREGNANCY AND ITS COMPLICATIONS

Hauser: Quadruplets and Their Mothers (Vierlinge und Vierlingsmütter). *München. med. Wchnschr.*, 1913, lx, 812.

By Zentralbl. f. d. ges. Gynäk. u. Geburtsh. s. d. Grenzgeb.

A 29-year-old quintipara gave birth to living quadruplets in the 28th to 30th week of pregnancy. The babies died within the first 24 hours. They were practically of equal size. Examination of the placenta revealed the fact that it was a case of two pairs of twins with three placentæ. The one pair came from two eggs, the other from one egg with one amnion. The author discusses the various hypotheses that might explain the possible origin of the two groups. His review of the literature and statistics shows that:

1. The mothers of quadruplets are, on an average, older than the mothers of triplets, and the latter older than those of twins.

2. The number of primipara giving birth to more than one child decreases with the increase in number of children of a pregnancy.

3. The mothers of quadruplets are nearly all multipara (VI-paræ or even more); the mothers of triplets and twins are also multipara (II- to V-paræ).

EISENBACH.

Füth: A Further Contribution on the Displacement of the Cæcum During Pregnancy

(Weitere Beiträge zur Verschiebung des Cæcums während der Schwangerschaft). *Deutsche Gesellschaft. f. Gynäk.*, Halle, 1913, May.

By Zentralbl. f. d. ges. Gynäk. u. Geburtsh. s. d. Grenzgeb.

In a five months' pregnant woman who had never had any trouble in the ileocecal region, Füth found the cæcum, the adnexa and the omentum glued to the posterior wall of the uterus and containing an abscess in which the appendix could not be found. The abscess was three to four fingers breadth above, and lateral to, the anterior superior spine. It was possible to bring down the cæcum without traction to the iliac fossa and fix it there. The trouble probably commenced with adhesions between adnexa and appendix, and the cæcum was drawn along with the appendix. There were no congenital anomalies of the ligaments or mesentery of the cæcum or ascending colon.

The author's observation has been corroborated by Korn, Babler, Schmitt and Cook, as well by the anatomical preparations of Hahn. A very valuable corroboration is offered by the studies of cæcum mobile and particularly by the fact brought out by Dreyer at autopsies that 75 per cent of all women possess an abnormally movable cæcum, whose movability extends downward to the small pelvis as

well as upward to the edge of the liver. In spite of all this the author does not consider the question of displaced cæcum during pregnancy as definitely settled and is not surprised that Renvall was unable to demonstrate a marked displacement of the cæcum in two women operated on during the sixth month of pregnancy.

Jaschke: Diseases of the Kidneys During Pregnancy in Women Suffering from Heart Disease (Nierenerkrankungen in der Schwangerschaft herzkranker Frauen). *Deutsche Gesellschaft. f. Gynäk.*, Halle, 1913, May.

By Zentralbl. f. d. ges. Gynäk. u. Geburtsh. s. d. Grenzgeb.

Normal pregnancy and especially labor put considerable demands on the heart, which may be dangerous. Although this hardly holds good for valvular lesions, it does pertain to diseases of the myocardium occurring either alone or with valvular lesions. Accordingly, it is evident that pregnancy complicated with heart and kidney disease is very dangerous. This applies only to such renal diseases as cause an increase in the work of the heart muscles; i.e., hypertony which is clinically evidenced by hypertrophy of the left chamber and finally by hypertrophy of the entire heart. The acute pregnancy kidney is not of any importance. Even if it is accompanied by a slight increase in the blood pressure, the latter may easily be combated by dietetic measures. In the chronic pregnancy kidney the blood pressure is markedly higher (170-180) and the work of the heart is increased. Yet by proper treatment the blood pressure can be kept within moderate limits. The occurrence of eclampsia is dangerous because it severely strains the heart. The highest demands are put on the heart by the so-called chronic nephritis in graviditate. It is impossible to distinguish the latter from the chronic pregnancy kidney. The high and persistent increase in blood pressure up to 250 or more, which is uninfluenced by treatment, explains why occasionally a well heart, and almost always a diseased heart, succumbs. The only help lies in removing the increased demands placed upon the heart by interrupting the pregnancy.

Jaschke: Kidney and Pregnancy (Niere u. Schwangerschaft). *Deutsche Gesellschaft. f. Gynäk.*, Halle, 1913, May.

By Zentralbl. f. d. ges. Gynäk. u. Geburtsh. s. d. Grenzgeb.

The relationship between high blood-pressure and low urine and chlorine elimination, suggested by Zangemeister is very misleading. In the first place, it is more complicated than he believes, and secondly, the decrease in the amount of urine and chlorides is

due to the increased perspiration. Polyuria is just as easily possible with a high blood-pressure as is oliguria. The amount of chloride eliminated is dependent on the amount of consumption and the avenues of exit. In no case can the kidney of pregnancy be explained on the ground of increased capacity of reaction.

Schmidt: Heart and Kidney Affections During Pregnancy (Herz- und Nierenkrankheiten in der Schwangerschaft). *Deutsche Gesellsch. f. Gynäk.*, Halle, 1913, May.

By Zentralbl. f. d. ges. Gynäk. u. Geburtsh. s. d. Grenzgeb

In practice the value of auscultatory findings in cardiac diseases is still overrated. The intensity of the murmur and the accentuation of tones are by no means parallel to the degree of defect. This is true also for initial stenosis, although this affection occupies a somewhat individual position. Of far more importance are the size of the heart, pulse changes, prolonged congestion of the liver, and lesser circuit, and, above all, functional ability and reserve force of the cardiac muscle. Not every break in compensation has the same significance in rendering a prognosis. The latter is dependent on the cause of the break, and how it responds to rest in bed and to digitalis. Myocarditis, although aggravated by pregnancy, is by no means always an indication for a therapeutic abortion. There are also many milder cases with slight arrhythmia and tachycardia, which are not indications. Between these there are many transitional forms. The milder forms of myocarditis following angina and other infections are due to bacteriotoxins. The question arises whether the cardiac muscle is affected more by the toxæmia incident to pregnancy or whether it is due to mechanical strain. Schmidt does not desire to go into detail in regard to the toxæmias of pregnancy, but says that, as Lutz has proven, there is a disturbance of balance of the organs of internal secretion quite frequently.

Definite rules cannot be laid down in regard to treatment. A break in compensation during the first half of pregnancy in combination with nephritis does not always indicate an interruption of the pregnancy. The author does not agree that obstipation causes the migration of germs through the bowel wall, but believe that it is catarrh of the bowel. The supposed lymph vessels between the colon and the pelvis of the kidney are still problematical. Colon infection for the bowel may also cause pulmonary, cardiac and renal disease, but only rarely pyelitis. According to Schmidt, the infection of the renal pelvis probably arises from the genital organs.

Stoeckel: Kidney Disease and Pregnancy (Nierenerkrankung und Schwangerschaft). *Deutsche Gesellsch. f. Gynäk.*, Halle, 1913, May.

By Zentralbl. f. d. ges. Gynäk. u. Geburtsh. s. d. Grenzgeb.

The author desires to make three points: First, that the kidney insufficiency in pregnancy is becoming more and more confusing, especially when only

the urinary findings are considered. At best, the urinary findings are only relative; the condition of heart and blood pressure are the deciding points. Second, a tuberculous kidney should be removed during pregnancy as well as at any other time. The pregnancy will not be compromised on that account, and the old theory that a serious additional strain would be thrown on the kidney is shattered by recent experiences. Women with one healthy kidney stand pregnancy surprisingly well. Third, the author believes that the pyelitis of pregnancy is merely a recurrence of a pyelitis which originally occurred during childhood. This is based on the fact that colon bacilli remain in the urine for many years after an attack of pyelitis in spite of treatment. He advises the combined treatment, the medicinal and dietetic as well as the surgical, with repeated pelvic irrigations. For the treatment of pyelitis of pregnancy the author is convinced that after a thorough trial of the internal treatment a therapeutic abortion is indicated to prevent severe injury to the kidney.

Fetzer: Kidney Function in Pregnancy and in the Toxæmias of Pregnancy (Über Nierenfunktion in der Schwangerschaft und bei Schwangerschaftstoxicosen). *Deutsche Gesellsch. f. Gynäk.*, Halle, 1913, May.

By Zentralbl. f. d. ges. Gynäk. u. Geburtsh. s. d. Grenzgeb.

The author conducted functional tests of the kidneys on numerous cases of pregnancy. He made five hundred NaCl and nitrogen determinations. From the usual kidney of pregnancy definite amounts of NaCl and nitrogen are excreted in one to two days, the nitrogen a little more rapidly than the NaCl. In other cases NaCl is alone retarded. The excretion of albumin, however, does not parallel the retention of NaCl. On a liberal salt-containing diet a retention of NaCl occurs without the immediate appearance of oedema. These cases demand a salt-free diet. A pure milk diet is not ideal as it is too poor in iron and contains too much nitrogen. Such cases are recognized only by early functional tests.

In eclampsia the excretion of NaCl is prolonged and increases; nitrogenous products also are markedly increased. This increase, however, does not show itself as in the ordinary kidney with increase in concentration, but by an increase in the quantity of urine. As soon as the eclampsia ceases the kidney resumes its function almost immediately; therefore a diseased kidney can hardly be taken to exist in eclampsia. Toxic influences must play a part analogous to anaesthesia, which inhibit the function temporarily and in particular the function of the kidney vessels. The persisting hypersusceptibility of the vessels during the puerperium also speaks for this fact. The total nitrogen of the blood is not increased in eclampsia. Therefore there can be no accumulation of globules in the blood. The nitrogen of end products, however, is moderately increased. The determination of the cause of this retention will probably clear the matter still further.

Eckelt: The Function of the Kidney of Pregnancy and the Eclamptic Kidney (Über die Funktion der Schwangerschafts- und Eklampsieniere). *Deutsche Gesellsch. f. Gynäk.*, Halle, 1913, May.

By Zentralbl. f. d. ges. Gynäk. u. Geburtsh. s. d. Grenzgeb.

Having performed experiments in metabolism the author comes to the following conclusions: The function of the kidney of healthy pregnant women in regard to water, sodium-chloride, and N-elimination is equal to that of non-pregnant women. These are interfered with in the kidney of pregnancy. It is not possible to predict an eclampsia on these grounds before the pains begin. The same holds good for blood-pressure and percentage of albumen. After the pains of labor have begun, a decrease in the sodium-chloride seems to indicate eclampsia. A decreasing titer and high albumen do not make the prognosis of an eclampsia worse. Nor is the prognosis of a kidney of pregnancy made worse by a decrease in the titer and an increase in the amount of albumen.

The kidney of pregnancy and the eclamptic kidney have the identical anomaly in function. Comparative studies of the blood-pressure, oedema and disturbance of the function of the kidney lead the author to the conclusion that the kidney of pregnancy is the expression of a direct parenchymatous disturbance, brought about by a toxin in the circulation.

Holzbach: The Kidney in Pregnancy and Nephritis in Graviditate (Über Schwangerschaftsnieren und Nephritis in graviditate). *Deutsche Gesellsch. f. Gynäk.*, Halle, 1913, May.

By Zentralbl. f. d. ges. Gynäk. u. Geburtsh. s. d. Grenzgeb.

Holzbach thinks the term "kidney of pregnancy" is anatomically unjustifiable, for degenerative and inflammatory processes blend into one another in the anatomical as well as in the clinical picture. He suggests a careful study of each case, in order to determine whether an insufficiency of the kidney exists. Schlayer's function test is of great diagnostic aid; it often reveals a masked nephritis. Chronic nephritis may develop from a kidney of pregnancy. These investigations have no bearing on eclampsia, and the author intimates that the latter be treated differently than nephritis.

Mayer: Pyelitis and Its Relation to Pregnancy (Über Pyelitis und ihre Beziehungen zur Schwangerschaft). *Deutsche Gesellsch. f. Gynäk.*, Halle, 1913, May.

By Zentralbl. f. d. ges. Gynäk. u. Geburtsh. s. d. Grenzgeb.

Pregnancy is not the cause of pyelitis, but predisposes to it. Many cases of pyelitis are descending infections. Organisms enter the pelvis by the blood or lymph stream, and by pus foci near by. The recently described lymphatic connection between the colon and the right pelvis probably accounts for the occurrence of infection by way of the lymph stream and explains the greater frequency of right-sided pyelitis; although normal bowel flux do not

penetrate the normal bowel wall, abdominal flux may very easily penetrate a changed bowel wall. Pyelitis is frequently preceded by acute gastric disturbances with changed intestinal flux. The serologic behavior also indicates an increased virulence of the bowel organisms. Appendicitis deserves particular consideration in the etiology of pyelitis. Pyelitis frequently leads to an early interruption of pregnancy. The child, although at term, is frequently undeveloped. An improvement occurs usually with the onset of the puerperium, although there are numerous exceptions, and a genital infection may follow. During pregnancy pyelitis must be differentiated, especially from appendicitis, occasionally from peritonitis, puerperal infection due to criminal abortion, acute respiratory diseases, and genital hæmorrhages.

Opitz: Pyelitis Gravidarum (Neue Beiträge zur Pyelitis gravidarum). *Deutsche Gesellsch. f. Gynäk.*, Halle, 1913, May.

By Zentralbl. f. d. ges. Gynäk. u. Geburtsh. s. d. Grenzgeb.

The author reports on the systematic examinations of bladder and kidney urine in 160 cases of pregnant women. Bacteria were found in almost $\frac{2}{3}$ of the cases, but a pyuria was present in only $\frac{1}{5}$ of them. *B. coli* was the organism most frequently found. Besides this most extraordinary varieties of organisms were isolated, even the yeast fungus being present in some cases. In the 160 women, twelve had a definite pyelitis. In addition there were four cases of pyelitis observed during the early months of pregnancy. As there were cases in which the kidney urine was sterile in the presence of a cystitis due to the usual pyelitis organisms, the author concludes that an ascending infection of the pelvis can hardly be questioned. The author does not deny the possibility of a lymphatic infection of the renal pelvis, but does not believe it occurs commonly, in view of the fact that cystoscopic examinations have proven that an ascending infection of the ureter occurs much more readily during pregnancy than at other times.

Kroemer: Etiology and Treatment of Pyelitis Gravidarum (Zur Ätiologie und Behandlung der Pyelitis gravidarum). *Deutsche Gesellsch. f. Gynäk.*, Halle, 1913, May.

By Zentralbl. f. d. ges. Gynäk. u. Geburtsh. s. d. Grenzgeb.

Kroemer, from thirty-eight cases of pyelitis, thirty-one of which were pregnant, arrives at the following conclusions: (1) Pyelitis in numerous instances is a long drawn out disease with a tendency to recurrence. It frequently follows infectious diseases, gastro-enteritis, colitis, thrombophlebitis, polyarthritis and angina. (2) Pregnancy predisposes to recurrence as it may cause obstruction of the ureter, manifesting itself first as a hydro-ureter, and pyelctasis with bacteriuria. (3) Pelvic irrigations and drainages are to be considered only as symptomatic treatment, which must be augmented by vaccine therapy and prolonged observation. (4) A continuation of a one-sided pyuria after the puerperium must

be considered as due to a manifest kidney lesion, and surgical treatment would seem advisable. (5) The possibility of a tuberculous affection of the kidney or pelvis must be considered in each case. (6) Congenital anomalies of the ureters and kidneys, floating kidney, or stricture of the ureter due to obliterating urethritis, must be considered.

Weibel: Serological and Clinical Phenomena in the Pyelitis of Pregnancy. 1. Antibodies in the Maternal and Foetal Blood in Cases of Pyelitis of Pregnancy (Serologisches und Klinisches über Schwangerschaftspyelitis. 1. Über Antikörper im mütterlichen und fötalen Blute bei Schwangerschaftspyelitis). *Arch. f. Gynäk.*, 1913, xcix, 245.

By Zentralbl. f. d. ges. Gynäk. u. Geburtsh. s. d. Grenzgeb.

Bacteriological investigations of the blood in cases of pyelitis, even in highly febrile cases, have always given negative results. The agglutination reaction in positive colon bacillus infection has been almost always negative. Weibel, therefore, demonstrated in eight cases of colon pyelitis of pregnancy the presence of haptens of the third order (Bordet-Gengou antibodies of the amboceptic type) using the complement fixation method. In all cases except one there were definite antibodies against the autogenous bacillus, in several cases antibodies in lesser quantity against foreign strains, but never any antibodies against any strain in normal serum. The investigations regarding bacilli found in the bowel were not uniform. However, in cases not infected no antibodies were produced against their own strain of bacilli in the bowel, and no immunity to their own flora. In all cases in which antibodies could be demonstrated in the mother they were present also in the child born of that mother, the sera of both usually being of the same type. Antibodies were found also in the amniotic fluid, but were much weaker in action. With the receding of the infection a drop in the immunity also occurs. In the serum of the infant the antibodies disappeared sometimes very quickly, at other times less quickly, a sign of passive immunity.

Weibel reports one case of particular interest, since a spontaneous recovery occurred during pregnancy without any treatment, characterized by disappearance of the antibodies from the blood, with sterile urine in the pelvis of the kidney and bladder at the time of labor. NITZSCHE.

Novak and Strisower: Concerning a Peculiar Form of Glycosuria in Pregnancy and Its Relation to Diabetis Mellitus (Über eine besondere Form von Glykosurie in der Gravidität und ihre Beziehungen zum echten Diabetes). *Deutsche Gesellschaft. f. Gynäk.*, 1913, May. By Surg., Gynec. & Obst.

The examination of fourteen cases of spontaneous glycosuria in pregnancy, conducted under known diets, led the authors to conclude that the glycosuria of pregnancy is usually entirely of renal origin. Sugar metabolism may be disturbed in individual cases, but oversensitiveness of the kidneys for sugar is usually to blame. In the last cases a combination of the two was noted. Real diabetes gives a very

poor prognosis: two cases in the last year in Wertheim's clinic died in coma. The normal content of sugar in the blood, failure of the clinical attributes of diabetes and the benign course distinguish the two forms. Careful clinical observation is necessary to distinguish the combined form. Hydramnios and intra-uterine fetal death are characteristics of real diabetes.

JAMES R. MILLER.

Shoemaker: Acute Membranous Vaginitis in Pregnancy Due to Enterococcus. *Penn. M. J.*, 1913, xvi, 703. By Surg., Gynec. & Obst.

Shoemaker cites two cases in which the enterococcus was the exciting cause of a severe vaginitis which began in the eighth month of pregnancy.

The symptoms were an extremely painful condition of the vulva and vagina with severe burning and itching. The patient was unable to sleep, and had to sit in a chair day and night. The vulva was swollen and the skin and mucous membranes reddened. A thick yellow-white discharge was present with non-adherent yellow masses in the vagina the size of a spoon bowl. The organisms in the first case were diplococci, or enterococci, while in the second case the streptococci, staphylococci, *Vibrio albacans* and fungus of thrush were associated.

Treatment: 1 to 100 solution of permanganate of potassium was used as a daily vaginal douche, while the vulva and surfaces of the vagina were painted daily with a fifteen per cent solution of argyrol. Both cases recovered within three weeks.

EUGENE CARY.

Sellheim: A Case of Rupture of the Uterus During Pregnancy (Ein Fall von Uteruszerreissung in der Schwangerschaft). *Deutsche Gesellschaft. f. Gynäk.*, Halle, 1913, May.

By Zentralbl. f. d. ges. Gynäk. u. Geburtsh. s. d. Grenzgeb.

The tearing of the uterine wall in a 41-year-old woman, secundipara, must have begun in the first two months of pregnancy, for at that time she had had severe abdominal pain and internal hæmorrhage. The movements of the child were no longer felt after the seventh month, and five weeks later menstruation set in. The menses occurred every four weeks thereafter.

Examination of the uterus excludes ectopic pregnancy, for the old scar was plainly visible in the fundus. It was probably a case of premature separation of the uterine wall, where the placenta had been located, thus allowing the ovum to slip out into the peritoneal cavity. The placenta may have functioned a little longer, but it and the ovum soon died. The uterine wall repaired itself and the menstrual flow became re-established.

Bannister: A Case of Extensive Rupture of the Utero-Vaginal Junction with Escape of the Placenta into the Peritoneal Cavity. *Proc. Roy. Soc. Med.*, 1913, vi, Obst. & Gynec. Sect., 237.

By Surg., Gynec. & Obst.

The patient, 35 years of age and pregnant for the tenth time, had had nine forceps deliveries. After

she had been in the second stage of labor with right occipito-posterior presentation, the physician applied forceps, rotated the head and delivered a still-born child. Two hours later, as the placenta had not been delivered, and as a slight hæmorrhage was persisting, manual delivery of the secundines was attempted, but the hand passed easily into the abdominal cavity. The cervix was lacerated and there was a large tear in the posterior vaginal vault. On opening the abdomen the peritoneal cavity was filled with blood and the placenta lay in front of the left kidney. The rent extended laterally over both utero-sacral folds into the pararectal pouch on either side, while below it reached the lowest limit of the pouch of Douglas.

As the case had been delivered under insanitary conditions in the home, a total hysterectomy was performed and both vaginal and abdominal drainage was used. While the etiology of this rupture is obscure, it would appear to have been spontaneous, as the physician used only very slight force in turning the occiput anteriorly. C. D. HOLMES.

Samgin: Pregnancy and Labor Complicated by Ovarian Cysts (Zur Frage der Schwangerschaft und Geburtskomplikation durch Ovarialcystom mit Beschreibung eines Falles von ruptura spontanea cystomatis ovarii sub partu). *Med. Rundschau*, 1913, iv, 324.

By Zentralbl. f. d. ges. Gynäk. u. Geburtsh. s. d. Grenzgeb..

According to the statistics of the Berlin Gynecological Clinic, five cases of ovarian cysts occurred in 17,832 labors; according to the University Lying-In Hospital of St. Petersburg, two cysts in 10,893 labors. Fehling says these are caused by a displacement and flexion in the ovarian tubes and according to the writer, another cause is the frequent interruption of pregnancy by ovarian tumors. According to Kerron, rupture occurs in 4 per cent of cases of pregnancy; according to Williams, in 3.4 per cent of cases of pregnancy, and in 8 per cent of cases of labor. The causes of rupture are suppuration, axial rotation, pressure by the enlarging uterus, softening of the cyst wall, trauma, abortion, forceps, and at times the action of labor pains. The prognosis depends on the nature of the cyst contents, recovery being the rule where this is serous, and when it is not, peritonitis and death.

As to whether an operation should be performed during pregnancy or during labor, the author inclines toward the latter, as the danger of atonic secondary hæmorrhages is too great during the course of pregnancy. It is only then indicated if dense adhesions exist between tumor and uterus. If the pelvis is markedly contracted, the method of choice is the abdominal or vaginal radical operation. Paracentesis of the cyst and the induction of abortion might also be considered. Abdominal ovariectomy during pregnancy has a mortality of 12½ per cent, and causes an interruption of pregnancy in 16 to 22 per cent. The best results, according to Dsirne, are obtained during the third or fourth

months. The vaginal operation (Dührssen) has a slightly lower maternal mortality than the abdominal operation; however, the number of interrupted pregnancies and the sacrifice of children is much larger. It is indicated in small movable cysts without adhesions. A list of literary references is given.

KRINSKI.

Beck: Multiple Sclerosis, Pregnancy and Labor (Multiple Sklerose, Schwangerschaft und Geburt). *Deutsche Ztschr. f. Nervenheilk.*, 1913, xlv, 127.

By Zentralbl. f. d. ges. Gynäk. u. Geburtsh. s. d. Grenzgeb.

Of the forty female multiple sclerosis patients treated in Tübingen, sixteen, or 40 per cent, attributed the onset of their disease to pregnancy and labor. In eight cases the disease commenced during pregnancy, in four immediately following the birth of the child, and in four independently of pregnancy and labor. In seven cases the disease became aggravated during pregnancy and in seven shortly after delivery. In one case the onset occurred during the first pregnancy, became aggravated in all five succeeding pregnancies, and always improved shortly after delivery. In a second case the sclerosis became so aggravated during pregnancy that therapeutic abortion was induced, followed by immediate improvement subjectively and objectively.

The interruption of pregnancy did not act as trauma in these cases, contrary to the view of Edinger; hence only the strain incident to labor can be taken into consideration as the exciting factor in the onset or in the course of the disease. On the contrary, it appears that pregnancy, considered by Offergeld as an exogenous etiological factor, probably is of much greater significance than labor and the puerperium. Practically, the prevention or interruption of pregnancy may be required in cases of multiple sclerosis, but definite rules at present must be formulated. HÖLDER.

Couvelaire: Surgical Treatment of Hæmorrhages Due to Separation of the Normally and Abnormally Situated Placentæ (Traitement chirurgical des hémorragies par décollement du placenta normalement et vicieusement inséré). *J. d. sages-femmes*, 1913, xli, 241.

By Zentralbl. f. d. ges. Gynäk. u. Geburtsh. s. d. Grenzgeb.

The author presents a résumé of the teachings and methods of the French school. Under surgical treatment the author understands hysterectomy and hysterotomy. In severe hæmorrhages due to low implantation of the placenta, the author prefers wide opening of the membranes, insertion of a Champetier bag or Braxton-Hicks version to surgical procedures. He gives statistics from numerous institutions of France. After subtracting the cases brought in in extremis, a 4 per cent maternal mortality is recorded. The principal danger is not hæmorrhage, but sepsis. The high foetal mortality is due to prematurity. In the cases which offer a hindrance to immediate delivery, as rigid cervix and infection, surgical treatment must be considered.

Hysterectomy is preferred in infected or suspicious cases; otherwise transperitoneal Cæsarean section. Vaginal and suprasymphyseal section are not employed.

With a normally implanted placenta severe hæmorrhages are rare. The author emphasizes the picture of utero-placental apoplexy. In these cases also he prefers the obstetrical methods of delivery if the os is soft and dilatable. Otherwise the surgical methods, as hysterectomy or transperitoneal section, are better, the former especially in cases of bloody infiltration of the uterine walls. Vaginal section is not recommended.

SCHIFFMANN.

McDonald and Krieger: Bilateral and Multiple Ectopic Pregnancy. *J. Am. M. Ass.*, 1913, lx, 1766.
By Surg., Gynec. & Obst.

Bilateral and multiple ectopic pregnancy are classified as follows:

Bilateral ectopic pregnancy: (1) Simultaneous; (2) different ages; (3) one ovarian, one tubal.

Twin tubal pregnancy: (1) Simultaneous; (2) different ages; (3) twins on one side and one foetus on the other.

It is difficult always to discover whether cases of double ectopic pregnancy are true twin pregnancies. Many cases which have been reported as twin pregnancies are cases in which one gestation has been retained in a tube and another has been deposited in the same tube. Also cases have been reported in which the first was retained as a lithopedion and a second tubal pregnancy occurred in the same tube. Several other combinations also have been seen and it is therefore difficult to state whether the foetuses in a twin tubal pregnancy are really twins and of the same age or whether it is only a repeated tubal pregnancy in which one conception has followed another in the same tube. Thirty-nine cases have been collected from the literature in which the evidence of twin tubal pregnancy was reasonably sure; that is, the foetuses were either the same size and character or were nourished by a single placenta, or the careful history gave no other record of more than one syncopal attack. The latter is not very accurate evidence but it is the best available. The authors then report two cases of their own.

In the first case the patient was 38 years old and had been suffering more or less for two months previous to operation. She had had several hæmorrhages but the last one was the most severe. On opening the abdomen large quantities of partly coagulated and fluid blood were found. The uterus, ovaries and blood clot filled the pelvis, and it was difficult to demonstrate the anatomical relations. The uterus was enlarged. The tumor masses on both sides and both ovaries were removed. Five days after the operation the uterus expelled en masse the remains of the placental tissue and foetus. One of the ovaries contained a corpus luteum. Both tubes were greatly enlarged and contained a brownish-red material. Connected with each tube was a foetus. One of them was well preserved while the

other seemed to have undergone an arrest of growth. In the one farthest advanced finger-nails, the external ear, eyes and face could be made out. In the other the lower limbs were well formed but the trunk and head was enclosed in a connective tissue capsule. The second patient was 28 years old. She did not suffer a great deal. She had had a continuous flow of brownish watery fluid since the last menstrual period. At operation the abdomen was found to contain only a small amount of free, blood-stained turbid fluid. The left tube was bound down by new-formed adhesions beneath the sigmoid. It was the seat of an ectopic pregnancy. The right ovary was macerated and lay behind the uterus and was bound down by adhesions in the pelvis. A second ectopic pregnancy with the foetus was found there. The anatomical diagnosis in this case was as follows: Double ectopic pregnancy. Chronic pelvic peritonitis. Decidual cells and chorionic villi shown by sections from the walls of the sac of each tube. Necrosis of the decidual tissue and thrombosis.

EDWARD L. CORNELL.

Muhsam: The Diagnosis and Treatment of Extra-Uterine Pregnancy and Report of Over 100 Continuous Operative Cures (Die Diagnose und Therapie der Extrauterine-gravidität, zugleich Mitteilungen über ein lückenlose Serie von über 100 operativen Heilungen). *Therap. d. Gegenw.*, 1913, liv, 199.

By Zentralbl. f. d. ges. Gynäk. u. Geburtsh. s. d. Grenzgeb.

The author reports 145 cases treated during the past five years. He discusses the etiology in regard to inflammation, age, number of pregnancies, and one child sterility. For differential diagnosis he advises puncture of the cul-de-sac in Fowler's position, the urobilin test and leucocyte counts. He employs also puncture of the cul-de-sac in cases of hæmatocele, and considers the danger of the procedure as insignificant. One hundred and eleven women were brought in in collapse, frequently under a mistaken diagnosis.

The treatment of extra-uterine pregnancy is absolutely operative, even in severe collapse. Muhsam operates by the laparotomy route, and employs the vaginal incision only in suppuration of the hæmatocele. The abdominal cavity is closed unless oozing of blood necessitates tamponade. The free blood in the abdomen is not removed during the laparotomy, but all patients are placed in the Fowler position and it is removed a few days later by vaginal incision or puncture. Among the 145 cases the author had a mortality of 9.5 per cent; in the last 108 cases, no death occurred. Nothing new is mentioned in regard to after-treatment; the remaining tube is not removed unless found diseased.

FRANKENSTEIN.

McCann: A Primary Ovarian Pregnancy at the Fourth Month. *Proc. Roy. Soc. Med.*, 1913, vi, Obst. & Gynec. Sect., 229. By Surg., Gynec. & Obst.

In order to prove that a pregnancy when advanced is ovarian it is necessary (1) that the

corresponding fallopian tube be intact; (2) that the ovary on the same side be absent; (3) that the foetal sac be connected with the uterus by the utero-ovarian ligament; (4) that ovarian tissue be discoverable in several portions of the sac wall. The macroscopical appearance and anatomical relations of this specimen seemed to indicate beyond doubt that this was a true ovarian pregnancy.

The patient was 32 years old and had one child 5½ years old. Her health was good. Menstruation was regular until Feb., 1910, when her periods ceased. Soon she began to have severe attacks of pain in the left lower abdomen. On May 29, 1912, she had a large cystic swelling in the left lower quadrant extending as high as the umbilicus. On June 7, the abdomen was opened. The tumor was found to be ovarian in character and connected with the uterus by the utero-ovarian ligament and to the broad ligament by the mesovarium. The left fallopian tube was quite free from the tumor and normal in appearance. The left side of the mass was cystic, while the foetus was in the upper part and to the right. Nothing abnormal was found in the right appendages.

The specimen proved to be a multilocular ovarian cyst consisting of two loculi. A septum separated these loculi from a third cavity which contained a foetus of about the fourth month with its placenta. The upper surface of the cavity was covered with a layer of recent blood-clot. The raw surface seen at the back of the specimen running between the loculi and the foetal sac represented the line of division of the entire tumor. The utero-ovarian ligament was directly connected with the foetal sac. The foetal sac consisted of an outer fibrous layer external to the amniotic lining, but where it was in apposition with the cystic portion of the tumor ovarian tissue was seen in the microscopical sections. The relationship of the pedicle to the tumor, and the fact that the utero-ovarian ligament was directly connected with the foetal sac, proved the specimen to be an undoubted example of ovarian pregnancy. A functionally active portion of the left ovary must have become impregnated, and the growing ovum evidently formed a sac for itself in this situation. The specimen further demonstrated the possibility that ovarian pregnancy may occur in an ovary already the seat of cystic tumor.

C. D. HOLMES.

Wilson: A Contribution to the Study of Eclampsia as a Toxæmia of Possible Mammary Origin. *Am. J. Obst., N. Y.*, 1913, lxvii, lxxx.

By Surg., Gynec. & Obst.

In this article Wilson carefully reviews the knowledge of parturient paresis of cattle and reports the cases of eclampsia in women that have had treatment directed to the breasts on the assumption that the breasts were the seat of the etiological toxine. He compares the points of similarity between the bovine and human diseases, and concludes his very interesting article as follows:

1. Parturient paresis is a disease of the parturient

cow, undoubtedly due to a powerful toxine in the blood having its origin in some perversion of the mammary secretion.

2. The mammary theory of eclampsia is based almost entirely on the pathological and clinical similarity of the two diseases.

3. There are, however, the following important differences:

a. Parturient paresis rarely attacks primiparous animals, while primiparity markedly predisposes to eclampsia.

b. Parturient paresis occurs almost entirely post-partum; eclampsia shows no especial predilection for this period.

c. Parturient paresis increases in frequency in direct ratio with increased power in milk production. No such finding has been noticed in eclampsia.

d. Sugar is an almost constant ingredient of the urine of parturient paresis but is rarely found in eclamptic urine.

4. The mammary theory of eclampsia is probably merely specious. At the same time, it deserves careful and thorough investigation and offers an attractive field for study. At least it may prove to be the explanation for the occurrence of a small proportion of cases.

5. Such an investigation should include:

a. A careful pathological and clinical study of parturient paresis.

b. The determination of the toxic or non-toxic character of the colostrum of eclamptics.

c. The tentative trial, in properly selected cases of eclampsia, of the treatment by air or oxygen injection of the breasts, which at least has the undoubted advantage of being harmless.

N. SPROAT HEANEY.

Engelmann and Elpers: The Viscosity of the Blood in Eclampsia and Other Diseases of the Female Organism (Über das Verhalten der Blutviscosität bei der Eklampsie sowie bei anderen Erkrankungen und Veränderungen des weiblichen Körpers). *Gynäk. Rundschau*, 1913, vii, 315.

By Zentralbl. f. d. ges. Gynäk. u. Geburtsh. s. d. Grenzgeb.

The determination of the viscosity of the blood was carried out with the apparatus of Hess. According to Hess, the viscosity of the blood of healthy non-pregnant women is 4.22, and according to Oehlecker 4.38. In pregnancy Engelmann and Elpers found it to average 3.66 between the seventh and tenth months. It approaches the normal about ten days after labor. In eleven cases of eclampsia, in which no treatment had been instituted, the average was 5.0, a 40 per cent increase.

A venesection of 560 ccm. reduced it 17 per cent. The venesection was still more effective if followed by an infusion of 1-1.5 L. of Ringer's solution which causes a drop of 33 per cent. After infusion alone the viscosity decreased 25 per cent. The authors studied the viscosity also in other diseases. In severe hæmorrhages due to abortion, myomata and tubal pregnancy, the viscosity was decreased most decidedly

in prolonged hæmorrhage due to fibroids (2.6). The usual loss of blood during labor had no influence. In six cases of placenta prævia the viscosity was reduced to 3.73 only; the newborn child, however, showed an increase to 5.8. It is of value in the differential diagnosis of adnexal inflammation, an increase to 5.45 being observed in ten cases, whereas in ten cases of extra-uterine pregnancy it was always reduced to 3.73.

BISCHOFF.

Lichtenstein: Further Experience with the Expectant Treatment of Eclampsia (Weitere Erfahrungen mit der abwartenden Eklampsiebehandlung). *Deutsche Gesellsch. f. Gynäk.*, Halle, 1913, May. By Zentralbl. f. d. ges. Gynäk. u. Geburtsh. s. d. Grenzgeb.

The author has again treated 94 cases by making a venesection and using Stroganoff's treatment. The maternal mortality was 5-5.3 per cent; the infant mortality 37.3 per cent in toto and 21.6 per cent of viable infants. Of the cases before labor 42 per cent were cured without interrupting the pregnancy. Seventy-four consecutive cases of eclampsia were cured without a death in 16 months.

If the cases are arranged according to the scheme of Fromme and Freund then the expectant treatment has a higher mortality than the active treatment; this merely signifies, however, that early treatment is better than late. It does not decide which treatment is the more feasible. The total number of deaths gives the best criterion as to the more desirable method to pursue. In the expectant treatment the death-rate is only $\frac{1}{2}$ to $\frac{1}{3}$, and 42 per cent of the cases are cured before delivery. In other words, there is no indication for active treatment in eclampsia and it is to be abandoned in preference to the expectant.

Kroemer: Disturbance of Kidney Function in Eclampsia (Störung der Nierenfunktion bei Eklampsie). *Deutsche Gesellsch. f. Gynäk.*, Halle, 1913, May.

By Zentralbl. f. d. ges. Gynäk. u. Geburtsh. s. d. Grenzgeb.

Kroemer reports on systematic examinations of urine in eclampsia with prodromal symptoms in pregnancy, labor and puerperium. Excluding the rare case without albumin, there is found, in addition to a large amount of albumin and casts, an oliguria with high specific gravity and a retention of chlorides. The latter is present in every case with œdema. The plotting of a curve makes the prognosis much easier, and offers reliable hints for the treatment. A sudden dropping of the curve shows a threatened eclampsia as well as a recurrence during the puerperium. By carefully watching this drop, Kroemer was able to combat the disturbances during the puerperium by means of venesection and the administration of larger quantities of water. The atypical cases without albumin and with normal NaCl excretion are the exception; they offer no prognosis and are adapted to the Stroganoff method of treatment. Functional tests of eclamptic kidneys with phenolsulphothalein confirmed the fact that

there was severe injury of the kidneys, since only 20 to 40 per cent of the urine substance was excreted; in first two hours up to 25 per cent. In healthy pregnant women the quantity runs from 60 to 75 per cent. This test may possibly make up the link in the determining functional activity of the kidneys. Investigations regarding the toxicity of the urine of eclamptics according to the methods of Franz and Esch resulted negatively. The liquor cerebrospinalis was absolutely non-toxic, the serum unreliable.

Nacke: The Treatment of Eclampsia (Eklampsie-therapie). *Deutsche Gesellsch. f. Gynäk.*, Halle, 1913, May.

By Zentralbl. f. d. ges. Gynäk. u. Geburtsh. s. d. Grenzgeb.

Opinions differ widely in regard to the treatment of eclampsia. On the one hand is Freund, on the other, Lichtenstein. The author himself had seventy-nine cases of eclampsia, with a mortality rate of 3.8 per cent. His slogan is to deliver severe cases immediately, less severe cases as soon as possible. He considers those which secrete a small amount of urine, have prolonged drowsiness and a small rapid pulse, as severe. He attaches no prognostic importance to the quantity of albumin and to the number of convulsions. One case of severest eclampsia was delivered during the eighth month by means of vaginal Cæsarean section and recovered; the convulsions ceased and the anuria improved. Definite conclusions should not be drawn from such a case, however, as milder cases ended fatally. One point, however, he desires to emphasize in regard to operative delivery; namely, the uterus it liberated from the dangerous muscular tension and the reflex irritation it induces; the pressure is removed from the abdominal vessels, especially those of the kidney; the diaphragm is allowed to recede, lungs and heart are not impaired, etc. The delivery therefore accomplishes the removal of a great number of complicating conditions which alone may cause death, even without eclampsia. Nacke considers the operative treatment far superior to venesection.

Freund: The Treatment of Eclampsia (Zur Eklampsie-therapie). *Deutsche Gesellsch. f. Gynäk.*, Halle, 1913, May.

By Zentralbl. f. d. ges. Gynäk. u. Geburtsh. s. d. Grenzgeb.

Between October, 1912, and April, 1913, 46 cases of eclampsia were treated expectantly (venesection and narcotics) at the Kgl. Charité in Leipzig. Four women died of eclampsia; four recovered during pregnancy. One severe case of eclampsia during the sixth month of pregnancy suddenly became worse during 48 hours of expectant treatment and the uterus was immediately evacuated by a vaginal cæsarean section. The foetal mortality has risen considerably by this method especially in eclampsia during pregnancy and early stages of labor. It was 41.9 per cent compared to 17.1 per cent in early delivery, excluding cases of puerperal eclampsia. Therefore it is still undecided which of

the palliative methods of treatment (expectant or premature delivery) is most favorable to mother and child.

In regard to other toxæmias of pregnancy, Freund reports 18 cases (16 cases of toxidermitis and 2 cases of hyperemesis gravidarum). The first 3 skin cases were cured by injections of serum from the pregnant woman; the following 4 were cured by horse-serum injections. To the other 9 and to the 2 cases of hyperemesis 200 cc. of Ringer's solution were given subcutaneously. All but 5 skin cases were cured; one of them was especially refractive. The remaining 4 had recurrences but 3 of them finally recovered spontaneously.

Ringer's solution is without doubt much slower in action than the serum, but it is advisable to employ one or two injections of it before resorting to the serum.

Vogt: The Obstetrical Significance of the Status Hypoplasticus (Die geburtshilfliche Bedeutung des Status hypoplasticus). *Deutsche Gesellsch. f. Gynäk.*, Halle, 1913, May.

By Zentralbl. f. d. ges. Gynäk. u. Geburtsh. s. d. Grenzgeb.

The most important and most frequent changes of hypoplasia, according to Bartel, are found in the lymphatic and the circulatory systems. The hypoplasia may involve either one of these alone, or only a part of one of them. The significance of this condition in obstetrics is shown by the report of three cases. The first concerns a primipara, 20 years old, in which a partial inversion of the uterus followed the expression of the placenta which already had become detached and was visible at the vulva. In spite of an immediate reposition and the moderate loss of blood, the patient died 3 hours later from cardiac failure. The post-mortem examination revealed an anæmia, normal genitals and adrenals with marked hypoplasia of the heart and entire circulatory system.

The second case was that of a very debilitated primipara, 40 years of age, in whom manual removal of the placenta was performed 4 hours and 15 minutes after labor. The patient soon died, although the loss of blood was slight. At post-mortem a general hypoplasia, a persistent thymus, a marked stenosis of the aorta and mal-development of the heart were found. In the third case, also a primipara, the pulse suddenly became poor after the delivery of the child by an extraperitoneal Cæsarean section. Artificial respiration and stimulation were unsuccessful. The amount of the anæsthetic used and the blood lost were small. Anæmia of all the organs and hypoplasia of the entire circulatory system was found post-mortem. Melchior attributes the death not only to a hypoplasia of the circulatory system with its tendency to parenchymatous hæmorrhages but also to a true oligæmia. Vogt verifies this opinion by the following clinical observations. The loss of blood from the operation in the second case was determined by Rübsamen's method and amounted to 390 cc. This quantity is slight.

In his case the loss of this relatively small amount of blood was sufficient to cause death in the presence of oligæmia, which latter is only a part symptom of a hypoplasia.

The following conclusions of importance to practical obstetrics can be deducted from these investigations: Hypoplastic individuals are very much endangered by labor. The conduct of the third stage requires particular attention, and, if possible, it should be expectant, but only as long as the general condition of the patient permits, because a relatively small loss of blood is sufficient to cause death. Surgical interferences are permissible only if based on the strictest indications, on account of the danger of the anæsthetic and the great tendency to parenchymatous and uncontrollable hæmorrhages. Even slight losses of blood may endanger life in primary oligæmia as shown above. The unexplainable cases of spontaneous inversion of the uterus in young primiparæ as observed by Mansfeld and Vogt find an anatomical explanation in a general hypoplasia and a debilitated constitution.

Kehrer: The Obstetrical and Gynecological Significance of Tetany (Die geburtshilflich-gynäkologische Bedeutung der Tetanie). *Arch. f. Gynäk.*, 1913, xcix; 372.

By Zentralbl. f. d. ges. Gynäk. u. Geburtsh. s. d. Grenzgeb.

The author discusses the reported cases of tetany during pregnancy, labor and the puerperium and then describes a number of observations; three cases of lactation tetany, two of tetany in mother and child, six cases of tetany in the new-born, two during pregnancy; one case due to oxalic acid poisoning and finally, eight cases following gynecological operations. He takes up first the clinical phenomena arising in conjunction with maternity, which shows an extraordinary variability. Especially interesting are his observations on tetany occurring during the first few days of infancy, as pediatric treatises do not recognize the disease before the second or third month. As far as the etiology is concerned, it is now positively known that the tetany of pregnancy as well as that due to lactation is identical with, and on the same basis as, that occurring after goiter extirpations — a deficiency of parathyroid secretion or hypoparathyroidism. An essential predisposition to a hyperfunction of the parathyroids is the lack of calcium in the body tissues and blood. Pregnancy and lactation especially predispose, therefore, to tetany, as during pregnancy the calcium of the maternal organism is required for the development of the foetal structures, especially the bones. During lactation the calcium is drained away in the milk and serves to nourish the child. The rational treatment consists in administering large doses of calcium. Adults receive five to six gm., the new-born 1 gm., per diem.

Food rich in calcium, as milk, yellow turnips, comfrey root (*radix consolidæ*) is advised. Narcotics cannot be dispensed with entirely. Venesection or other loss of blood is contra-indicated on account of

the loss of calcium incident thereto. The success obtained with the modern method of treatment of tetany does not necessitate the prevention of conception or the interruption of pregnancy. JAEGER.

LABOR AND ITS COMPLICATIONS

Terzaghi: Fever During Delivery; Obstetric Indications for Its Treatment (Febbre in travaglio; Criteri che guidano la condotta dell'ostetrico). *Arte ostetr.*, 1913, xxvii, 70.

By Zentralbl. f. d. ges. Gynäk. u. Geburtsh. s. d. Grenzgeb.

The author reports the case of a primipara in labor, normal in every respect except that her temperature was 39° C. and the child was presented by the breech. After a chill, delivery was effected by aid of the forceps and breech hook. The pulse varied from 96 to 100, and the fever disappeared a few hours after delivery.

The author considers the case one of fever due to intoxication. As a differential point between infection and intoxication, he places great stress upon the pulse. A temperature of 38° he considers physiological, on account of the uterine activity. Temperature before rupture of the membranes is rare. If it drops immediately after, the case is probably one of intoxication, otherwise it must be considered as an infection, especially if there has been operative interference under uncertain sepsis. Intoxication fever is indication of rupture of the membranes and spontaneous delivery, whereas in infection rapid delivery is indicated. Injuries are to be avoided as are also incision of the cervix and episiotomy. Version after the membranes have ruptured is contra-indicated on account of danger of rupture of the uterus; the author prefers perforation, even of the living child. High forceps is to be avoided. The infants die frequently, during the first few days, of umbilical infection or pneumonia.

SEMON.

Kusmin: Pelvic Outlet Tumors a Hindrance in Child-Birth (Über Beckenausgangstumoren als Geburtshindernis). *Med. Rundschau*, 1913, iv, 343.

By Zentralbl. f. d. ges. Gynäk. u. Geburtsh. s. d. Grenzgeb.

In the two reported cases spontaneous delivery was impossible, due to a tumor in the birth-canal.

In the first case the diagnosis of carcinoma of the ovary was made. The tumor was located in the paravaginal tissue in the wall between the vagina and rectum. The clinical and microscopical examination showed it to be due to a congenital anomaly of the left Müllerian duct in its upper third. The ovary remained in its original position next to the lumbar vertebrae. The carcinoma most likely began here and after it had grown in size it slipped down into the pelvis. The tumor was removed per rectum and the child delivered with forceps.

Case 2 proved to be a submucous fibroid of the posterior lip of the os uteri. The tumor was removed per vaginam and this child also was delivered with forceps.

KRINSKI.

Ziegler: What Can Be Accomplished with the Method of Deventer-Müller for the Delivery of the Shoulders (Was leistet die Deventer-Müllerische Entwicklung des Schulter-gürtels)? *Beitr. z. Geburtsh. u. Gynäk.*, 1913, xviii, 271.

By Zentralbl. f. d. ges. Gynäk. u. Geburtsh. s. d. Grenzgeb.

The advantages of the Deventer-Müller method for the delivery of the shoulders are simplicity and rapidity of execution, even for the inexperienced, and less danger of infection and injury to mother and child. The disadvantages consist in danger of severe injury to cervical spine, naturally caused only by carelessness or by forced application of the maneuver in severe dystocia. The greatest importance lies not in the application of the method for the delivery of the arms, but of the shoulders. If the arms are flexed they are delivered simultaneously with the shoulders. If they are extended the upper arms become so easily accessible that high traction on them will deliver them. Only when they lie in the nape of the neck may delivery by this method become very difficult or impossible. Von Herff considers the expression of the child by an assistant as essential to retain the flexed attitude of the arms and head.

The author is able to report 401 cases to date in which this method of delivery was used at the Basel clinic, with only 2.5 per cent of fractures as compared to 18 per cent in 225 cases delivered by the usual methods. Detailed statistics of maternal mortality and morbidity, as well as foetal mortality, cannot be given at the present time, but the figures all speak in favor of the Deventer-Müller method.

SCHMID.

Zangemeister: A Maneuver for the Correction of a Face Presentation (Handgriff zur Umwandlung der Gesichtslage). *Deutsche Gesellschaft. f. Gynäk.*, Halle, 1913, May.

By Zentralbl. f. d. ges. Gynäk. u. Geburtsh. s. d. Grenzgeb.

The author desires to present a new maneuver for the correction of a face presentation. It is based on former methods yet in its combination possesses something individual and, what is more important, serves its purpose in a much simpler and protective manner. It is as follows: The hand corresponding to the face (in mento laero anterior the left) is inserted upward alongside of the chin, the thumb is hooked into the mouth and the fingers are laid upon the thorax. The chin is pushed upward by the thumb and the tips of the four fingers force the chest toward the mother's back while the outer hand forces the buttocks toward the child's abdomen. It will be seen that with this maneuver the correction of the body position as well as the rotation of the head can be carried out with two hands, whereas another person is necessary to carry out the Thorn maneuver. In addition the hand is inserted into that side of the lower uterine segment which is stretched the least.

The author employed this maneuver in a series of cases. The correction was accomplished very easily.

That it is not always successful is due to conditions. As the occiput is considerably drawn out in primary face presentations and the position of the breech rather a stubborn one, there may be a recurrence of the face presentation after correction. In one case the correction failed on account of a foetal goiter and existing meningocele. But that was a case surely not adapted to correction. The author does not deem it advisable to try the maneuver in every case of face presentation, but under certain conditions he considers it a very valuable procedure for the benefit of mother and child.

Rizzacasa: Death Due to Rupture of Oesophageal Varices Occurring During Labor (Morte di una partorente per rottura di varici esofagee). *Giorn. internaz. d. sc. med.*, 1913, xxxv, 301.

By Zentralbl. f. d. ges. Gynäk. u. Geburtsh. s. d. Grenzgeb.

The patient, a woman of 35, was admitted in the ninth month of her fourth pregnancy. She complained of burning in the throat and of parasthesias in the hands. She appeared dull and melancholy. A few days before delivery hæmorrhage of the gums occurred, and a few days later severe hæmatemesis. Two days later labor set in. The presentation was a face presentation with the child deeply asphyxiated; attempts at resuscitation resulted in failure. The woman suffered several more attacks of hæmatemesis and in spite of all treatment died shortly after delivery.

At the autopsy the hypophysis was found to be twice its normal size; the thyroid also was enlarged. The liver was contracted, weight 800 gms.; the spleen increased in volume and consistency. Numerous varicose dilatations were found in the venous plexus of the oesophagus. A large amount of black blood was found in the stomach and oesophagus. The direct cause of death was the hæmorrhage from the oesophageal varices.

BERBERICH.

Langes: Fatal Intraperitoneal Hæmorrhage During Labor Due to Rupture of the Uterine Veins (Intraperitoneale Verblutung intra partum infolge von Venenruptur des Uterus). *Zentralbl. f. Gynäk.*, 1913, xxxvii, 537.

By Zentralbl. f. d. ges. Gynäk. u. Geburtsh. s. d. Grenzgeb.

This is the report of a case of rupture of the uterine veins during labor in a bipara 32 years old. The labor began six weeks before term. Severe pains were suddenly felt in the abdomen about fifteen hours later with a sensation of an internal rupture. Seven hours after the attack a severe syncope with loss of blood took place. When medical assistance reached the patient, the abdomen was very tense and hard. The uterus could not be distinctly outlined. The foetus was not plainly palpable, but the foetal heart could be heard. The patient was pale and the pulse was 90. A foot was brought down to accelerate labor and the escaping amniotic fluid was free of blood. Symptoms of an internal hæmorrhage existed with dullness in the lower left abdominal region. An exploratory

puncture revealed the presence of clear blood. On immediately opening the abdominal cavity, a large amount of blood was found free in the peritoneal cavity. The blood was flowing in a thick stream from a perforation in the uterine serosa which was the size of a dime and located at about the level of the uterine os at the left lateral posterior border of the uterus. The child was dead. A supravaginal amputation of the uterus was performed. The patient died two hours afterwards.

Besides a severe anæmia of all the organs nothing else was found at autopsy. A sound introduced into the perforation of the uterine serosa entered an open blood vessel. Pathological changes could not be recognized in this defective area. Serial sections show a rupture of a large, thin-walled varicose vein closely situated underneath the serosa. The varicose enlargement plus the pressure caused by the labor must be considered as the etiological factor of the rupture.

Similar cases are reported in literature. A differential diagnosis must be made from rupture of the uterus, rupture of an extra-uterine pregnancy (combination of an intra-uterine with an extra-uterine pregnancy or gravidity in an accessory cornu), premature detachment of a normally inserted placenta, and rupture of blood vessels in the region of the spleen, or near the uterus. To enable one to recognize such cases the author recommends paracentesis with a fine cannula.

EISENBACH.

Reinhard: Medical Treatment for Weak Labor During Parturition (Zur medikamentösen Behandlung der Wehenschwäche während der Geburt). *Deutsche med. Wchnschr.*, 1913, xxxix, 747.

By Zentralbl. f. d. ges. Gynäk. u. Geburtsh. s. d. Grenzgeb.

Experiments with coffeinum natrio-salicylicum having failed to increase labor, Reinhard used pituitrin, which had no effect in three cases and caused lasting contractions which endangered the life of the child in three others. Pituglandol gave good results in seventeen cases and failed in three; it caused tetanus uteri lasting fifteen minutes in two cases. Secale-dialysat-Golaz given in doses of 0.5 gm., and eventually given repeatedly, gave good results in twelve cases and none in two cases. It never caused tetanic contractions. The scarcity and weakness of labor is mainly influenced, not the duration.

MOHR.

Vogelsberger: The Galvanization Treatment of the Uterus According to Bayer in Conjunction with Pituitrin as a Means for the Artificial Induction of Premature Labor and Labor at Term (Über Galvanisationsbehandlung des Uterus nach Bayer in Verbindung mit Pituitrin, als Mittel zur künstlichen Einleitung rechtzeitiger und vorzeitiger Geburt). *Med. Klin.*, 1913, ix, 620.

By Zentralbl. f. d. ges. Gynäk. u. Geburtsh. s. d. Grenzgeb.

The author recommends galvanization of the uterus in combination with pituitrin for the artificial induction of premature labor. The procedure was carried out in 23 cases. Any transportable battery

is sufficient. A current of 10-20 MA. is necessary. A cathode, a sound-like electrode, is introduced high into the cervix. The anode is in the shape of a plate and is laid on the abdomen over the fundus and sides of the uterus and is moved until a contraction is produced. A few minutes' rest and the procedure is repeated. If no spontaneous contractions result in 20-30 minutes an interval of two hours is allowed to pass. If no spontaneous contractions set in during the first session we must conclude that no excitability exists on that day and repeat the treatment. No vaginal douche with antiseptics is given before galvanization as the mucous membrane offers protection against possible burns.

Pituitrin in conjunction with galvanization is not advised at the onset as a contraction of the cervix occurred in three cases, similar to its action without galvanization. Therefore, pituitrin should not be used until a cervical dilatation of at least three fingers is present. In abortions the cervix must be completely effaced. Then with 1 cm. of pituitrin the progress is hastened considerably. Four cases of miscarriage and six premature labors were treated. It failed in only two of the artificially induced abortions. The cause for the failure is the low excitability of the uterus in the middle months of pregnancy. As a rule only two to three sessions were necessary. In one instance twelve sessions were required. Powerful contractions set in spontaneously, increased by pituitrin until delivery occurred. In three cases pituitrin was not necessary at all. Labor lasted 12 to 48 hours; in one case 4½ days.

The indication in most cases was premature rupture of the membranes without contractions following. There are no disadvantages to the galvanization method. Its advantages over the older methods are: 1. It guarantees a normal labor; because the stimulation with galvanization is similar to the physiological stimulation; 2. There is less danger of infection than in intra-uterine manipulations or in blocking the secretions as in tamponade. WOLFF.

Kehrer: Subcutaneous Symphysiotomy of Frank
(Die subcutane Symphysiotomie von Frank). *Arch. f. Gynäk.*, 1913, xcix, 294.

By Zentralbl. f. d. ges. Gynäk. u. Geburtsh. s. d. Grenzgeb.

Kehrer reports in detail ten cases treated with the subcutaneous symphysiotomy of Frank and emphasizes the technique. As a result of the operation, the symphysis separates 2 to 3 cm. To prevent injury to the erectile tissue the author in the future intends to divide the ligamentum and the crura clitoridis with a double edged knife close to the bone for a distance of two cm. on both sides. The advantages over hebosteotomy are, above all, the prevention of injury to the bladder with resulting vesico-labial fistulae, urinary infiltration of the connective tissue, smaller symphyseal hæmatomata, prevention of callous formation with resulting contraction, permanent enlargement of the transverse diameter of the pelvis and firm cartilaginous union. The disadvantages are the transient œdemas of the

vulva extending from the hæmatoma, which may prolong convalescence indefinitely. To prevent their formation Kehrer advises early rising of the patient. All general contracted and flat rachitic pelvis (c. v., over 6.8 cm.) in anterior as well as posterior positions, oblique or transverse positions with prolapse of cord or extremity and brow presentations are the indications for this operation. The child must be at term and alive. Spontaneous expulsion is to be expected but pituitrin is administered when the pains are weak.

The operation is contra-indicated in infected cases and where infection is suspected. It encroaches upon the fields of the classical Cæsarean section, extraperitoneal section, high forceps, perforation of the living child, prophylactic version and premature labor. The last four operations mentioned are not to be considered for obvious reasons. The operation can be performed under ether, chloroform or sacral anæsthesia. The results in regard to the patient's ability to walk are excellent. The mortality in eighty-eight cases found in literature was zero for mother and child.

KLAUSS HOFFMANN.

PUERPERIUM AND ITS COMPLICATIONS

Jardine and Kennedy: Three Cases of Symmetrical Necrosis of the Cortex of the Kidneys. Associated with Puerperal Eclampsia and Suppression of Urine. *Lancet*, Lond., 1913, clxxxiv, 1291.
By Surg., Gynec. & Obst.

The authors give the clinical histories of their cases and describe the pathological findings. The first patient showed all the symptoms of eclampsia except convulsions. The second patient had only one convulsion. All these were delivered prematurely and in only one case was a live child born.

The kidneys, which appeared to have been healthy organs, were the seat of symmetrical necrosis of the cortex. The necrosis was more or less limited to the outer two thirds of the cortex, and in degree corresponded to the suppression of the urine. There was extensive thrombosis of the cortical blood-vessels which did not extend beyond the margin of the necrotic area and did not involve the vascular arches.

C. H. DAVIS.

Rübsamen: Clinical and Experimental Investigations Concerning the Action of Oxytoxic Substances During the Puerperium (Klinisch-experimentelle Untersuchungen über die Wirksamkeit der Wehenmittel in der Nachgeburtsperiode). *München. med. Wchnschr.*, 1913, lx, 627.

By Zentralbl. f. d. ges. Gynäk. u. Geburtsh. s. d. Grenzgeb.

The type of the contractions of the uterus and the influence of oxytoxic substances upon its motor function can be studied very graphically during pregnancy and labor, but no such investigations have been carried out as yet during the puerperium. Rübsamen has been successful in devising a method for the determination of the motor function of the fresh puerperal uterus. According to him, the post-

partum movements of the uterus are in the form of contractions.

On the basis of his studies with glandutrin, pituitrin and pituitrin he concludes that the postpartum contractions are influenced powerfully by those substances, especially in atony of the organ. Contractions are obtained within four to six minutes following intramuscular injection and within ten to thirty seconds following intravenous injection; this also in those cases in which no contractions could be elicited by the usual methods. In six cases of severe atony, as well as in ten mild cases, the hæmorrhage was controlled with an intravenous injection of glandutrin alone. The author hopes that all intra-uterine manipulations will eventually be discarded in favor of the use of hypophyseal extract on account of the danger of infection. It is possible also under normal conditions to decrease the physiological placental hæmorrhage by giving an injection of extract of the hypophysis.

The author shows in a conclusive manner the value of the "prophylactic method" in six cases of placenta prævia and in fourteen cases of classical Cesarean section. In contradistinction to pituitrin, the action of secacornin occurs only after twenty or thirty minutes, and its maximum action is not attained until one and one half hours after administration. Similar or even inferior in action are other ergot preparations. Ergot increases only the intensity of the contractions; it does not shorten the pauses immediately as does pituitrin. Hæmorrhages occur during the interval and not during the contractions. The author's investigations, therefore, prove that secacornin alone does not influence atonic hæmorrhages.

SCHMID.

Huggins: Differential Diagnosis and Treatment of Puerperal Infection. *Penn. M. J.*, 1913, xvi, 695.
By Surg., Gynec. & Obst.

The author emphasizes the desirability of exactly locating the puerperal infection. If some intra-abdominal condition is strongly suspected, the author believes an exploratory incision should be made in order to palpate the ovarian veins, etc.

Treatment: The most important barrier against infection is a healthy patient; in other words, a woman should be under the care of a physician from the beginning of pregnancy. The author condemns the use of the curette and removes retained placental tissue only when the uterus is soft and baggy; this he does carefully with the finger. He drains local abscesses and peritonitis cases early, and keeps the patient in the sitting posture and out of doors all the time.

EUGENE CARY.

Schweitzer: Prophylaxis of Puerperal Infection (Zur Prophylaxe puerperaler Infektion). *Deutsche Gesellschaft. f. Gynäk.*, Halle, 1913, May.
By Zentralbl. f. d. ges. Gynäk. u. Geburtsh. s. d. Grenzgeb.

In spite of all the precautions taken to prevent the occurrence of an external infection in the puerperal woman, there are, nevertheless, a fair number of

infectious cases for which an autogenous origin must be assumed. It occurs usually in those cases which during pregnancy had a pathological vaginal secretion. The author advises a prolonged douche treatment before labor in all women with such a secretion. Lactic acid is used in $\frac{1}{2}$ per cent solution. This inhibits the growth of cocci and most pathogenic bacteria. The cocci after daily douches are gradually replaced by the normal flora of the vagina. After a daily douche for ten days the pathological secretion gradually returned to normal in 90 per cent of the cases; 89 per cent of those harboring the streptococci became free of this organism. The bacilli which replace the pathological germs are acid-resisting and acid-producing organisms, which augment and continue the action of the lactic acid. Concentrated solutions of lactic acid and other antiseptics only injure the secreting portion of the vagina and are not beneficial.

Among 1,500 women who remained in the clinic some time before delivery there was a morbidity of 10 per cent; excluding those who had only a few douches (one douche daily for ten days being considered as necessary), the morbidity was 7.3 per cent; 7.1 per cent in cases with normal vaginal secretion; and 30-40 per cent in cases with pathological secretions. The author therefore attributes this reduction in morbidity to the beneficial action of the $\frac{1}{2}$ per cent lactic acid douches, and advises its use as a prophylactic in the latter days of pregnancy.

Stoddart: Puerperal Insanity. *Clinical J.*, 1913, xliii, 189.
By Surg., Gynec. & Obst.

In this article Stoddart discusses insanity occurring in the puerperium, but he believes that puerperal insanity is a misnomer. It is his belief that there is no complex of symptoms that would lead one to diagnose puerperal insanity if he did not know of the existence of a recent delivery. This kind of insanity usually occurs in persons predisposed to mental disorder, or may be caused by intoxication or infection, and he calls it "intoxication or infection psychosis" or "acute confusional insanity." Patients who usually develop mania or melancholia are troubled with the constitutional psychosis, and heredity plays a part in about seventy per cent.

In the treatment of septic cases serum therapy is used, but it seems to have little control over the mental condition. Breast feeding should be stopped and the milk dried up in all cases. Rest in bed, proper feeding, and narcotics for sleep are all necessary.

EUGENE CARY.

MISCELLANEOUS

Fromme: The Relations of Affections of the Heart to Pregnancy, Delivery, and Puerperium (Die Beziehungen der Erkrankungen des Herzens zu Schwangerschaft, Geburt und Wochenbett). *Deutsche Gesellschaft. f. Gynäk.*, Halle, 1913, May.
By Surg., Gynec. & Obst.

There is no proof for the teaching that the heart hypertrophies in normal pregnancy. The heart in

pregnancy appears lighter than normal because of the relative increase in body fat. An increase in the volume of blood in pregnancy has also lately been disproved. Blood pressure increases in the second half of pregnancy and can reach values above the limits of normal. In labor there occurs great variations in pressure independent of the individual labor phase. So the heart must be supposed to do increased work in pregnancy and labor.

Accidental murmurs occur in 10-15 per cent of cases in the latter half of pregnancy, due probably to the kinking of the pulmonary artery. Bradycardia occurs in 20 per cent of all post-partum cases. This is often combined with respiratory arrhythmia.

The functional ability of the heart is the only important prognostic point. Older ideas of danger from heart disease in pregnancy and labor must be abandoned. The combination occurs in from 1.5 per cent to 2.5 per cent of all cases. Among 200 such cases 3 died, or if the number of pregnancies be reckoned, 1 in 200. Older figures, e. g., 38.5 per cent mortality among heart disease cases, represent only decompensated cases. Seventy-five per cent to 80 per cent of all heart cases are free from every heart symptom in pregnancy. Among 100 such cases, 98 have no circulatory disturbances and atony is not more common than elsewhere. Only rarely does one find after normal pregnancy and labor disturbances of the heart in the puerperium.

Premature labor occurs in 5.9 per cent, abortion in 4.8 per cent of heart cases, more often than in normal.

Mitral stenosis is especially dangerous. Stenosis alone or in combination with insufficiency occurs in only 28.8 per cent of all mitral cases, but the death rate is 75 per cent of all mitral cases. Complications are common; thus, 16.6 per cent of all fatal cases were recurrent endocarditis, 29.4 per cent acute and chronic nephritis, pneumonia and lung tuberculosis in 6.8 per cent each, as well as emphysema, bronchitis, pleuritis, pericarditis, scoliosis, narrow aorta and obesity.

Primary or secondary myocardial degenerations are especially endangered by pregnancy. Obstetricians overestimate the dangers of labor in heart cases. No therapy except diet is necessary for heart cases having no symptoms in pregnancy. Cases of light decompensation should be first treated medically if primipara, or if multipara who have in previous labors had no decompensation. If this is not speedily effective, interruption of pregnancy should take place in any month of pregnancy. Interruption is also indicated in myocardial degeneration, high grade mitral stenosis, or in cases complicated by other diseases. Sterilization should be done at the same time, but never at other times simply because of heart diseases. Operative labor should be done only in presence of decompensation. Compression of the abdomen after birth is to be recommended. Marriage should be advised against only when decompensation has occurred.

Old primipara with heart lesions are especially

endangered, for, as Sellheim showed, accommodation after 40 years is very slight. Fromme agrees with Küstner that the after-life of heart cases is shortened. Aneurisms often rupture in labor. Sudden death in pregnancy occasionally occurs without any previous warning. Fromme lays great stress on rhythm, and warmly recommends MacKenzie's overnight atelectasis test. Medical treatment should never be tried too long; cases that do not respond quickly give high mortality.

J. R. MILLER.

Zoeppritz: Serum Diagnosis of Pregnancy (Serodiagnostik der Schwangerschaft). *Deutsche Gesellsch. f. Gynäk.*, Halle, 1913, May.

By Zentralbl. f. d. ges. Gynäk. u. Geburtsh. s. d. Grenzgeb.

After many vain attempts with Abderhalden's dialysis method, the technique has now been so mastered that the results in the last fifty cases at the Göttingen clinic were perfect, in spite of the fact that some of the cases were carcinoma, pus cases, etc. The error had been in the preparation of the placenta. The author advises aspirants to acquire the technique at Abderhalden's institute and to carefully follow every step as there prescribed.

Rübsamen: The Biological Diagnosis of Pregnancy by the Aid of the Optic and Dialysis Methods (Zur biologischen Diagnose der Schwangerschaft mittels der optischen Methode und des Dialysierverfahrens). *Deutsche Gesellsch. f. Gynäk.*, Halle, 1913, May.

By Zentralbl. f. d. ges. Gynäk. u. Geburtsh. s. d. Grenzgeb.

The author made use of both of Abderhalden's methods in 100 cases. In anæmia and pus infections, one must use tubes containing 1 cc. of serum in making the dialysis test. In a case of pruritus during pregnancy, the dialysis reaction was more strongly positive before the successful serum therapy than later. In 10 cases of eclampsia the author got a weak reaction according to both methods. Three other cases reacted differently.

As a rule, the prognosis is favorable in proportion to the degree of splitting up of the eclamptic serum. In cases of hyperemesis gravidarum, the author got a weak reaction. Four cases that later proved to be ectopic pregnancies gave a positive reaction. In cases of endometritis post-abortum the optic method did not suffice and the dialysis reaction was weakly positive. Two cases of carcinoma and male blood gave negative reactions with the placental material. In every one of the 100 cases the author's results were ideal, and his observations check those of Abderhalden.

Lichtenstein: Abderhalden's Dyalitic Procedure (Über das Dialysierverfahren nach Abderhalden.) *Deutsche Gesellsch. f. Gynäk.*, Halle, 1913, May.

By Surg., Gynec. & Obst.

The author examined 74 cases by the Abderhalden reaction, 40 pregnant, and 34 others. Only once did a non-pregnant woman give a positive test. Ascites, amniotic and spinal fluids gave negative tests. Eclamptic serum with eclamptic and normal

placenta give very strong reactions. One case gave a negative result, but the foetus had been dead for from three to four weeks, and the reaction does not last that long.

J. R. MILLER.

Schlimpert: Experimental Research in the Physiology of the Hypophysis (Experimentelle Untersuchungen zur Physiologie der Hypophyse). *Deutsche Gesellsch. f. Gynäk.*, Halle, 1913, May.

By Surg., Gynec. & Obst.

Examinations were made on the rabbit's ear according to Bissemski's method. In no month of pregnancy could an increase of hypophysin be demonstrated. Hypophysin is only found in the posterior lobe. Extracts of other parts of the brain developmentally connected with hypophysis gave no reaction. By the method employed, the hypophysis was demonstrated in bovine embryos as early as the tenth week; in man from the sixth month on. In such experiments the action of histamin, a product of putrefaction, must be excluded.

J. R. MILLER.

Basset: Clinical Experiences with Pituglandol (Klinische Erfahrungen mit Pituglandol). *Med. Klin.*, 1913, ix, 457.

By Zentralbl. f. d. ges. Gynäk. u. Geburtsh. s. d. Grenzgeb.

In 20 cases, following the use of pituglandol, weak pains were strengthened and uterine contractions, which had ceased, began again. This took place three to ten minutes after injection, and its action lasted from two to two and one-half hours. Usually the length of labor was very short. The danger of tetanus is less with pituglandol than with pituitrin. Pituglandol can be given to primipara and multipara where there is little dilation of the cervix, and where the head is floating above the brim of the pelvis, if the soft parts are not too rigid and the relationship between the size of the head and the size of the pelvis is normal. Cumulative action and secondary weakening of uterine contraction do not occur. Intravenous injections are dangerous. They can not be depended on to bring about an abortion, but after uterine contractions have begun, and in an incomplete abortion, they give good results. In three cases of full-term pregnancy, labor and delivery followed injection of pituglandol.

WETZEL.

Zanfognini: Organotherapeutic Value of Adrenalin in Pregnancy (Organoterapia surrenomidollare in ostetricia). *Ann. di ostet. e ginec.*, Milano, 1913, xxxv, 247.

By Zentralbl. f. d. ges. Gynäk. u. Geburtsh. s. d. Grenzgeb.

The author cites fifty cases in which there were good results following the treatment of severe cases of vomiting of pregnancy with adrenalin. The results depend on the the quality of adrenalin used. The treatment is commenced with twenty to thirty drops of adrenalin hydrochloride a day, increasing the dose three to ten drops daily until improvement sets in. In very severe cases the dosage is increased to eighty or one hundred drops daily. When the symptoms are lessened and the condition is im-

proved, the dose is gradually decreased. The duration of the entire treatment is twenty to thirty days. There have been no complications or serious after-effects on uterus or foetus following this treatment, even in those very serious cases where four to five mg. of adrenalin were administered daily.

SEMON.

Ziemke: The Value of the Caput Succadaneum as a Sign of "Vital Reaction" (Die Bedeutung der Kopfgeschwulst als Zeichen der vitalen Reaktion). *Vierteljahrsschr. f. gerichtl. Med.*, 1913, xlv, Suppl. No. 1, 113.

By Zentralbl. f. d. ges. Gynäk. u. Geburtsh. s. d. Grenzgeb.

The author placed isolated leeches and between them Bier's pumps and periodically exerted powerful suction on the entire surface of the body of a dead foetus in order to determine whether the caput could be formed in a dead foetus. These areas were then examined macro- and microscopically, and resembled in every way the sections of the caput.

VOIGHT.

Koch: Modern Ecbolico, with Special Reference to B-Imidazolythämin (Kritische Betrachtung zur Frage unserer modernen Wehenmittel mit besonderer Berücksichtigung des B-Imidazolyäthylamins). *Zentralbl. f. Gynäk.*, 1913, xxxvii, 564.

By Zentralbl. f. d. ges. Gynäk. u. Geburtsh. s. d. Grenzgeb.

Koch finds betaimidazolyethylamin (histamin) much like pituitrin. On injection of $\frac{1}{4}$ -1 mg. into the portio, pronounced labor-pains soon developed. The hæmorrhage would stop but in the course of 10-24 hours the uterus would again become inert and the hæmorrhage so pronounced that a second injection would be necessary.

A rapid involution of the uterus was brought about during puerperium by giving 6 drops of a 1:500 solution of the drug three times daily. He treated thirty-three patients, twenty-five women having injections during labor (maximum dose 1 mg.). Secondary reactions were noticed in 70 per cent of the cases. These were headache, parched mouth, palpitation, etc. The inertia uteri recurred in three cases, in two of which the atony became very pronounced, but the author has had similar experiences with pituitrin. He had three cases of intra-partum death in pituitrin medication, two of which were due to the stormy contractions of the uterus.

WIENER.

Dessauer: Pelvic Measurement by Means of X-Rays (Beiträge zur röntgenologischen Beckenmessung). *Deutsche Gesellsch. f. Gynäk.*, Halle, 1913, May.

By Zentralbl. f. d. ges. Gynäk. u. Geburtsh. s. d. Grenzgeb.

Dessauer and Kehrer describe an apparatus with which they are able to take measurements of any internal point or organs. They realized the inability to measure distances by one picture, even though all the different points are on the plate. They connected the focus of the tube and the two pictures taken, with two threads, which cross each

other. The picture is taken from two different points, and the exact distance can be read off by means of these threads. The pictures can be taken from any angle. The apparatus is adapted not only to taking pelvic measurement, but also for determining the size of organs or the distance of any two points within the body. It is simple in construction.

Perrando: The Significance of Meconium in Dissections of the New-born (Del meconio rispetto agli indizii che ne sono desumibili necroscopie del neonato). *Riforma med.*, 1913, xxix, 325.

By Zentralbl. f. d. ges. Gynäk. u. Geburtsh. s. d. Grenzgeb.

The meconium is doubtless of great importance in forensic post-mortem autopsies. Its variety may allow conclusions as to the age of the foetus. In stillborn children more or less meconium is found in the liquor amnii. The colon may be absolutely empty, this being caused by direct pressure more often than by disease, by monstrosities and injuries of the central nervous system. With atresia of the intestines there is no meconium in the lower portions of the intestines; above the lower portions, it has a specific character and is of pathological importance for congenital atresia of the bowels.

Maceration does not cause any particular changes in the meconium and its elements can be differentiated up to the second and third stage. The meconium is quickly emptied, though not without exceptions, in foeti that died few days after parturition.

BERBERICH.

Franz: The Toxicity of the Urine During Pregnancy, Labor and Puerperium (Über die Giftigkeit des Harnes in Schwangerschaft, Geburt und Wochenbett). *Deutsche Gesellsch. f. Gynäk.*, Halle, 1913, May.

By Zentralbl. f. d. ges. Gynäk. u. Geburtsh. s. d. Grenzgeb.

On the basis of numerous investigations the author concludes that the urine of healthy pregnant women is not more toxic than the urine of non-pregnant women; and that in many cases the urine is more toxic during labor than during the puerperium. During the puerperium it is slightly more toxic than during pregnancy. The urine is highly toxic in toxæmias of pregnancy, and especially in eclampsia. Esch and Zinsser have lately confirmed these findings, although Esch only occasionally noted a drop in temperature due to the toxicity of the urine, whereas the author observed it quite frequently. The urine in fatal cases of eclampsia is less toxic because of the retention of the toxic substances, the result of injury to the kidneys or to an incomplete metabolism in which the albumin products are not split up completely. To draw valuable conclusions from this work the urine of the individual case must be examined repeatedly during pregnancy to determine the relative toxicity of that urine, and so become aware of dangers when they arise. The clinical picture must always be considered, and especially the kidney function of the patient.

Fowler: Lower Arm Type of Obstetric (Brachial) Paralysis; Report of a Case. *Internat. J. Surg.*, 1913, xxvi, 196.

By Surg., Gynec. & Obst.

The case reported was that of a girl three years old who had a paralysis involving the fore-arm. The condition had been present since birth and had followed forcible traction on the arm by the midwife in attendance. The radial head was found dislocated. The hand was flexed at the wrist with slight ulnar deviation, the thumb was adducted and extended. There was hyperextension of the proximal phalanges; the distal phalanges were flexed upon the proximal. Diagnosis: musculo-spiral and ulnar paralysis.

The causes of this condition are several. The most common is tension on the nerve roots during delivery. It may occur in either breech or vertex cases. When the head is hyperextended the nerves are put on a stretch and traction may very easily overstretch them.

The treatment should be surgical and is necessarily a procedure of some magnitude. The general condition of the child should be carefully considered before attempting the operation. Operations which may be performed are: (1) Nerve implantation, (2) excision of damaged nerve tissue followed by suture, and (3) plastic operations for contracture deformities.

J. H. SKILES.

Hinselmann: The Origin of the Syncytial Lacunæ in Human Ova (Die Entstehung der Syncytiallakunen junger menschlicher Eier). *Deutsche Gesellsch. f. Gynäk.*, Halle, 1913, May.

By Zentralbl. f. d. ges. Gynäk. u. Geburtsh. s. d. Grenzgeb.

Human ova, early in the second month, were serially sectioned ($\frac{1}{2}$ to 3). The proliferating Langhans cells penetrate into the decidua basalis as anastomosing syncytial trabeculae. In this way the highly complex network of syncytial tissue arises. The maternal tissue in these projections dies off as a result of the choriolytic action and the refuse is carried away by the blood and lymph. Circumscribed parts of the syncytium may increase in the plasma and amitotic nuclear division may be present. The meshes are then no longer in one plane, but are surrounded by a delicate syncytial network, but develop into caverns that are surrounded more or less by syncytial membrane.

As soon as the human ovum becomes implanted, this syncytial system begins to develop. Then the tryptic cells of the mucosa function and the refuse of the maternal tissue is carried away by the blood and lymph streams; thus the whole organism becomes affected.

Gerstenberg: Remarks on Rotter's Method of Treating Contracted Pelvis (Bemerkungen zu Heinrich Rotters: "Verfahren zur Heilung enger Becken"). *Zentralbl. f. Gynäk.*, 1913, xxxvii, 409.

By Zentralbl. f. d. ges. Gynäk. u. Geburtsh. s. d. Grenzgeb.

The chiseling off of a piece of the promontory of a contracted pelvis to the extent of $1\frac{1}{2}$ to 2 cm.

according to the method of Rotter-Schmid is a rather serious procedure for static reasons. Gerstenberg found in skeletonized pelvis after operation an average increase of 2.88 and 2.72 cm. respectively for the sagittal measures of the lower surface of the fifth lumbar and the upper surface of the first sacral vertebra. During operations on fresh cadavers the author found continued and serious hæmorrhages from the first sacral vertebra. The anterior longitudinal ligament is especially broad in this region and a considerable portion is left behind on both sides after the operation. The procedure lengthens the true conjugate and also, in a certain sense, the transverse diameter. In the delivery the head is not pushed as far forward by the decreased promontory and, therefore, does not enter the pelvis through the more anteriorly situated smaller transverse diameter as under ordinary conditions, but through the larger transverse diameter. The shortest anterior posterior diameter now runs from the lower edge of the chiseled off portion of the promontory (middle of the first sacral vertebra) to the symphysis. If the former true conjugate was seven centimeters, then the new conjugate is still so small that a serious hindrance during labor is to be expected. Therefore, the operation should not be performed in pelvis with a conjugata vera of less than 8.5 cm. It is of advantage only in connection with induced premature labors.

WAGNER.

Kriwsky: Concerning Hebosteotomy (Zur Frage von der Hebosteomie). *Monatschr. f. Geburtsh. u. Gynäk.*, 1913, xxxvii, 435.
By Zentralbl. f. d. ges. Gynäk. u. Geburtsh. s. d. Grenzgeb.

After a minute discussion of the views of different authors on hebosteotomy, its behavior after the division of the pubis, the character of pelvic union, permanent widening and repetition of the procedure several times on the same person, the author presents his conclusions based on personal experience, on clinical observations and on literary data, adding two histories. 1. Hebosteotomy does not represent a cureall for contracted pelvis but takes a fixed place amongst obstetrical operations. 2. Within certain limits hebosteotomy is comparatively free of danger and the operation of choice in multipara with a slight degree of contracted pelvis. The conjugate vera should not be below 7. cm. 3. The experiences gained from case reports permit us to perform hebosteotomy also in primipara even in an emergency, if otherwise a perforation of the living child only could come in question and other methods of delivery as Cæsarean section cannot be employed. It is self-evident that in these cases the condition of the soft parts must be especially considered and that prophylactic measures, as Schuchardt's paravaginal accessory incision according to the proposition of Van de Velde, must be used.

4. The least dangerous method is Döderlein's. 5. Labor must be immediately terminated by a corresponding obstetrical operation after hebosteotomy. 6. The after-treatment does not demand any special appliances, an early lateral position is to be recommended. 7. Union of the separated bones takes place very soon, either a bony or a connective tissue cicatrix being formed. 8. A permanent widening of the pelvis by a lengthening of its diameter or by increase in elasticity frequently does not take place which represents a disadvantage of a hebosteotomy. 9. The mode of delivery necessary in subsequent labors remains undecided even if hebosteotomy had been performed several times in the same patient.

HÖHL.

Fraenkel: Investigations in Regard to the So-Called "Glande Endocrine Myometriale" (Untersuchungen über die sogenannte Glande endocrine myométriale). *Arch. f. Gynäk.*, 1913, xcix, 225.
By Zentralbl. f. d. ges. Gynäk. u. Geburtsh. s. d. Grenzgeb.

The author was able to corroborate the findings of Ancel and Bouin in regard to the presence of the "glande endocrine myométriale" (gland with an internal secretion in the myometrium). The author's investigations were conducted on the uteri of pregnant guinea pigs. The structure consists of nests or strandlike cell groups within the inner circular muscle layer of the uterus in the neighborhood of the placental site. These cells, 5 to 37 μ in length, vary in form, being spindle shaped, three cornered or polygonal, with granular protoplasm and no cell membrane. The round nuclei are mostly small (1 to 6 μ) and centrally located, without definite chromatic figures. These cells lie either singly in tissue clefts or lymph spaces, or in larger groups between muscle fasciculi. In the mucous membrane and in the outer longitudinal layer they are found only rarely. With the von Gieson stain they are sharply differentiated from the muscle fibres and connective tissue, the cells being dark brown with the nuclei dark blue.

They have been found between the twenty-first and twenty-sixth days of pregnancy only, and then not constantly. In regard to their histogenesis nothing definite can be stated. Morphologically they are different from the placental wandering and giant cells. Being confined to the placental area and the retro-placental muscular layer, as well as occasionally to the decidua, they have migrated from the placenta to the syncytial wandering cells. The vascular relation of these nests proves they are not of a glandular nature. In contradistinction to other glands with internal secretion, capillaries are found only in small numbers between the cells. The functional significance of these cells is, therefore, still in doubt.

SCHINDLER.

GENITO-URINARY SURGERY

KIDNEY AND URETER

Smith: Bilateral Nephrolithiasis. *N. Y. M. J.*, 1913, xcvi, 1282. By Surg., Gynec. & Obst.

The author states that he performed successfully seventeen bilateral nephrolithotomies in cases of bilateral nephrolithiasis, with the technique given below. The operations were performed under nitrous-oxide-oxygen-ether anæsthesia, either in sequence or the three merged to meet the immediate conditions. He placed the patients laterally, nearly prone on the table, and elevated the kidney area by a Cunningham's attachment. An incision is made in the lumbar region. The renal vessels were held by the fingers during the kidney incision and subsequent manipulations; drainage of the kidney was employed. The hemispheres were approximated by three ligatures carried around the kidney and tied, leaving no suture material in the kidney substance, following the advice of Moore. The author believes that it is often desirable to incise the kidney pelvis when the radiograph shows stone in the pelvis only, and the kidney is not otherwise diseased. There was no urinary fistula when the kidney was incised and drained.

Following operation the patients were given normal salt solution by proctoclysis. After a few hours the head and shoulders were elevated and the patients were given an abundance of water by mouth with urinary antiseptics. If anuria threatened the drains were removed temporarily; hot packs applied to the entire body and hot fomentations over the kidneys; and diuretin was given hypodermatically. The author thinks that the calculi are probably bilateral in from 20 to 50 per cent of cases, and if both kidneys harbor calculi, it is probably better to operate on both at one time, if the patient's condition, which must be determined during the course of operation, will warrant the additional operation. With the above mentioned methods, he is of the opinion that the mortality is encouragingly low, and the ultimate results, measured in life and function, are in the great majority of cases most satisfactory. J. RADDA.

Arcelin: Biliary Calculi Causing Errors in Renal Radiography (Les calculs biliaires causes d'erreur en radiographie rénale). *Lyon méd.*, 1913, cxx, 1129. By Journal de Chirurgie.

Cases are frequently met in which there are thought to be both urinary and biliary stones, when in reality only the biliary stones are present. Nearly every one believes that biliary stones give no shadow on the X-ray plate, so if by chance a biliary stone does show and the clinical symptoms are

such that there is some doubt concerning the diagnosis, and there is blood and albumin in the urine, a diagnosis of urinary calculus is made.

Shadows of biliary calculi resemble closely those of renal, and the differences are not clearly understood. Most radiographers and surgeons have never seen or have never correctly interpreted plates showing biliary calculi.

Arcelin has collected two cases in which radiographs of the urinary tract have disclosed biliary stones in patients having urinary symptoms. Arcelin had a case in which the plate showed the shadow of ten faceted calculi, polygonal in form, with more or less rounded edges, below the twelfth rib at the level of the first, second and third lumbar vertebræ. The periphery of the stone alone gave a shadow. The shadows corresponded to the location of the gall-bladder and a diagnosis of gall-stones was made. The patient was not operated upon.

Goullioud reported a case in which there were stones casting shadows similar to those described above, at the level of the twelfth rib. The appearance of the shadow was like that of the shadow cast by a uric acid stone. An operation for renal stone was advised on account of the predominating renal symptoms. Pyelography was not attempted. Nothing was found at operation; at autopsy a few days later one large stone was found in the common duct and sixty faceted stones in the gall-bladder, which did not show in the radiograph.

In order to make radiography more accurate, such causes of error must be recognized and studied further. J. DUMONT.

Isobe: Experiments on the Influence of an Injured Kidney upon the Other Kidney (Experimentelles über die Einwirkung einer lädierten Niere auf die Niere der anderen Seite). *Mitt. a. d. Grenzgeb. d. Med. u. Chir.*, 1913, xxvi, 1.

By Zentralbl. f. d. ges. Chir. u. i. Grenzgeb.

The author occluded the blood vessels of one kidney in rabbits and dogs, extirpating the other kidney after a longer or shorter interval. The onset of total necrosis of the occluded kidney was followed by the resorption of decomposition products having a toxic effect on the other kidney, as shown by epithelial desquamation and more or less pronounced parenchymatous changes. This reaction persisted for one to two months when the necrotic kidney reduced to a small calcified mass produced no more toxic substances. If the urinary passages of only one kidney were occluded or the occlusion of the blood vessels was preceded by nephrotomy with implantation into the omentum, or decapsulation and enveloping with omentum, whereby a collateral cir-

culatation was established, there occurred in the other kidney nothing beyond a questionable hypertrophy. There was still some toxic substance produced if the renal substance became necrotic suddenly and in circumscribed areas.

In extending his studies to the liver, excising a part, enveloping it with omentum and implanting it in the abdominal cavity, the author found that when one kidney was extirpated the necrotic liver section produced only general toxic manifestations and no special alteration in the kidney itself. He concludes that the kidney gives rise to a specific, toxic substance, which acts on the kidney. **OEHLER.**

Kocher: The Operative Treatment of Floating Kidneys (Zur operativen Behandlung der Wander-niere). *Cor.-bl. f. schweiz. Ärzte*, 1913, xliii, 545.
By Zentralbl. f. d. ges. Chir. u. i. Grenzgeb.

The author describes a new method of nephropexy which he employed in a recent case. It consists in removing a strip from the fascia lata 18-20 cm. wide and 4 cm. long and suturing the middle to the capsule of the lower pole of the kidney and anchoring the two ends to the fascia lumbocostalis and lumbodorsalis. This makes a fascial sac into which the kidney fits like a stone into a slingshot. **REINHARDT.**

Caulk: The Etiology of Kidney Cysts. *Ann. Surg.*, Phila., 1913, lvii, 840. By Surg., Gynec. & Obst.

The author prefaces his article by reporting a personal case of a renal cyst due to an obstructive calcareous papillitis. It occurred in a man, forty-six years old, who complained of a dull aching pain in the right side, beneath ribs, occasionally reflected along the course of the ureter into the scrotum, suprapubic soreness, low backache, pain in right hip, slight increased frequency of urination and hæmaturia. The prostate was moderately enlarged. Cystoscopy was negative while endoscopy revealed a large, dark-red, bleeding verumontanum with the whole posterior urethra congested. Owing to these findings the author thought symptoms were of prostatic and vesicular origin. Radiographs showed a shadow in the bony pelvis on right side, probably a ureteral calculus. At operation the right kidney was found enlarged at the lower pole. It was opened and a cyst discovered filling one of the pyramids. This was shelled out and the cavity cauterized. The kidney was closed with interrupted sutures, and the patient recovered.

Caulk states that the main theories as to the etiology of these cysts have been the retention theory, the new formation theory, the theory that colloid changes of the epithelial and connective tissue cells serve as an origin, the congenital theory and the theory of Krause, which is that the kidney cysts are sometimes secondary to atrophy of the renal lobes in early life, corresponding to an obliteration of one of the branches of the renal artery. The author believes that the prevalent idea that cysts even of medium size cannot originate through obstruction of inflammatory origin, is erroneous, as

in his own case there was a definite inflammatory obstruction and a fair sized cyst.

The true etiology is obscure in most cases. Serous cysts are infrequent. In 2,610 autopsies at Middlesex Hospital, Morris met with but five cases; Israel found but one case in 297 surgical affections of the kidney. That the malady is one of adult life has been shown by Simon, who collected 52 cases and found only seven of them under the age of twenty. We cannot associate renal cyst with any particular disease, though many have reported such diseases as pneumonia, typhoid fever, dysentery, gall-stones, gout, etc., as precursors. Pousson believes that diseases which produce nephritis may aid in the production of kidney cysts. Of the drugs and poisons, corrosive sublimate, phosphorus, glycerine, aloin, vinylamin, etc., have been thought to be of etiological moment. Petterson and Tollens have tried, experimentally, to produce cysts of the kidney but without success. Levaditi, working on mice, rabbits, guinea-pigs and goats, has been able to produce, by the subcutaneous injection of vinylamin, papillary necrosis and sclerosis.

Serous cysts may be single or multiple, generally unilateral, situated either in the cortex or medulla, and they vary in size from that of a walnut to that of a child's head. Rendu's case of renal cyst contained ten litres of fluid.

The symptoms referable to kidney cysts vary greatly. The small cysts usually pass unrecognized during life and are found post-mortem, while in large ones the symptoms depend upon size, location, pressure effects, presence of infection and hæmorrhage. Pain is present in but 60 per cent of cases and when present is usually localized. Hæmaturia is rare.

The diagnosis has seldom been made, even in cysts of large size. It has been confused with floating kidney (and it should be noted that the association of cysts with floating kidney has been observed in a number of instances), hydronephrosis, solid renal tumors, ovarian, splenic, hepatic, omental, pancreatic and mesenteric cysts, and ascites. Cystoscopy, ureter catheterization, functional tests, and X-ray have been of little service in differentiating the lesion.

For cysts of moderate size the most satisfactory operation, as utilized by Tuffier, Bardenheuer, Ricard, Recamier and Albarran, is excision of the cyst. Morris advises partial nephrectomy when the cyst is situated in one pole of the kidney. In very large cysts which have destroyed most of the kidney substance, complete nephrectomy is advised. The collected statistics of Quenu, Lejars, Albarran and Tuffier show 54 nephrectomies with 34 cures and 20 deaths.

H. W. E. WALTHER.

Berner: The Cystic Kidney; Studies Regarding Its Pathologic Anatomy (Die Cystenniere, Studien über ihre pathologische Anatomie). Kristiania: Eig. Verlag, 1913.

By Zentralbl. f. d. ges. Chir. u. i. Grenzgeb.

The author by means of serial sections, graphic and plastic reconstruction, has studied in detail 28

cases of cystic kidney, 11 of which were congenital. The remaining 17 were those of adults up to 80 years old. He has found no points in favor of Virchow's papillitis theory and has never found any signs of inflammatory processes. The accumulations of small chromatin-rich cells which are found in the cortex as well as in the medulla, have been attributed to inflammatory processes by many observers. The author, however, believes that they are due to persisting nephrogenous tissue. The sudden formation of small epithelial cysts in this tissue speaks for that fact. The author considers them similar to normal "vésicules rénales" which are the anlage to the formation of Bowman's capsule and the excretory tubules. Furthermore all transitions from these little vesicles to cyst formations, the size and appearance of a Bowman capsule (in which no capillary tuft is present) can be seen.

The fact that polymorphonuclear cells have never been found and there has never been observed any diffuse connective tissue formation such as occurs in all inflammatory processes speaks against the inflammatory origin. The typical location of these masses of round cells also speak for its persisting nature; it is found occasionally along the periphery of the kidney so that one is reminded of the neogenous zone of the embryonal kidney.

In accordance with his own theory Berner was able also to demonstrate developmental disturbances which at one time involve one part, at another other areas of the urinary tract. The usual developmental error that could be demonstrated was the fact, that the two anlagen from which a normal kidney develops remain separated in the cystic kidney. This is proven most easily in the isolated Malpighian bodies from which blindly ending normal urinary tubules are occasionally seen to project. In a few of his cases collecting tubules were entirely absent. Even though in the literature the minute canals are frequently spoken of as collecting tubules the author calls attention to the surprising similarity between the normal collecting tubule and the atypical epithelial vesicle. He frequently observed collecting tubules with atypical branding and with a very irregular appearance.

In the pelvis of the kidney he was able also to demonstrate developmental anomalies, for instance, the occasional persistence of the single-layered flat epithelium — a typical arrest. At other times the pelvis showed atypical forms with large cystic cavities. The author discusses them in detail. In all his cases he was able to demonstrate developmental anomalies. In a fair number of them there were signs which must be attributed to tumor formation such as papillomatous excrescences, long connected epithelial bands, masses of free epithelial cells, epithelial vesicles floating within the cysts, many-layered epithelium and solid epithelial masses. Many such small compact masses are undoubtedly rests destined for the formation of a Bowman capsule. There is no doubt that epithelial proliferation occurs frequently in cystic kidneys. The question is

whether it is primary or secondary to the disease discussed. Secondary epithelial proliferation is frequently found following inflammatory conditions, but these are absent in cystic degeneration. In many cases the epithelial proliferation is clear and definitely of primary or tumor nature. The author holds to the view that cystic degeneration has nothing to do with retention, that each cyst is the result of a proliferation and in many cases may take on characteristics of an adenoma. In other cases these hyperplastic characteristics are absent and the picture is more that of a developmental anomaly. The developmental anomaly always precedes the epithelial proliferation. The cystic kidney in other words is a combination of a developmental anomaly plus a new growth. In individual cases one or the other factor may predominate.

All epithelial proliferation occurs in abnormal parts of the kidney. The author has never seen a normally functioning secreting tubule or a part of such which was the focus from which tumor-like proliferation originated. In regard to the occasionally occurring cartilaginous islands in cystic kidneys, the author's view coincides with that of Cohnheim and Wilms, i. e., that the structure is a mixed tumor and the cartilaginous islands are probably sclerotomal rests. He does not believe that they are due to a metaplasia. In the author's material there are quite a number of cases in which such cartilaginous islands occurred. The "horny pearls" which have been found only by Ruckert and the author are contained in cystic kidneys as well as in renal adenomas and are due to ectoblastic rests. The author also considers the presence of smooth muscle as belonging to the heterotypes, as he never found smooth muscle tissue in the stroma of the normal embryonal kidney. The presence of fat and mucoid tissue is explained on the same basis.

NILSEN.

Scheidemandel: The Infectious Diseases of the Kidney and Urinary Passages (Die infektiösen Erkrankungen der Nieren und Harnwege). *Abhandl. a. d. Ges. d. prakt. Med.*, 1913, xiii, 179.

By Zentralbl. f. d. ges. Gynäk. u. Geburtsh. s. d. Grenzgeb.

The author differentiates three types according to the manner of invasion by the infecting organism: 1. Hæmatogenous (descending) infection from bacteria which find their way in some manner into the blood stream. 2. Urogenous (ascending), arising from the lower urinary passages. 3. Infection via the lymphatics from the intestine. Infection from the blood stream is characterized by involvement of the parenchyma. The clinical picture in this condition, usually described as suppurative nephritis, is very variable. Urinalysis has demonstrated a direct bacterial invasion from such foci as the tonsils, middle ear and other local foci. Perinephritic abscess is produced by microbic invasion of the perirenal fatty tissues, the chief source of infection being furuncles of the skin.

The symptoms are high fever, sensitiveness of the kidney to pressure, severe constitutional depression.

With the accumulation of pus there is swelling and oedema in the lumbar region. In the early diagnosis positive urinary (bacteriological) findings are very significant. Invasion of the kidney alone is almost invariably hæmatogenous. When there is involvement of the renal pelvis one must consider, in addition to descending infections, ascending (*B. coli*) infection from the bladder and infection via the lymphatics. Against the preponderance of hæmatogenous invasion is the fact that, in the young, pyelitis is almost exclusively a disease of the female. A potent factor in promoting invasion by the motile *B. coli*, is a condition of urinary stasis. Infection through the lymphatics has its anatomical basis in the lymph passages reaching from the cæcum and ascending colon to the right kidney. According to Mueller's researches, it is possible for an invasion to occur via the lymph spaces in the walls of the bladder and ureter.

There are two significant points in the history, previous bladder irritability and nycturia. The sensitiveness of the involved kidney may vary. Muscular hyperalgesia and cutaneous hyperæsthesia are more constant. Mueller's method for recognizing pus in the urine is especially helpful. The reaction in *B. coli* infections is constantly acid. Hæmaturia in uncomplicated cases is extremely rare. The bacteriological diagnosis is important as the author found the causative organism to be the *B. coli* in 85 per cent of his cases. When possible ureteral catheterization is indicated to find whether one or both kidneys are involved. A bacteræmia is demonstrable in severe cases. The serodiagnosis in *B. coli* infections is unsatisfactory. The temperature curve is characteristic—chills and fever at first constant, with a deferescence in 5-6 days. A low pulse tension and undisturbed respirations differentiate this disease from pneumonia. The alternate fever and apyrexia is also characteristic.

Repeated relapses lead to bilateral involvement. Out of 125 cases but twelve occurred in the male. The preponderance of right-sided involvement is pronounced. A correlation between menstruation and pyelitis is noteworthy, 20 per cent of cases occurring in pregnant women. Pyelitis of pregnancy makes itself most felt in the second half. Here, too, in unilateral cases the uterus is in physiological dextroversion. Pyelography discloses generally dilatation of the ureter at its entrance into the true pelvis, or a dilatation of the renal pelvis. In the case of defloration, pyelitis resulting from the first attempt at coitus, there is at first involvement of the bladder and after a few days pains in the lumbar regions. The prognosis in an uncomplicated case of pyelitis is favorable. A chronic condition may persist for years without any extension of the process. Bacteruria is often the final stage.

The author inclines towards the medicinal treatment. Vaccine treatment is uncertain. In the more severe cases ureteral catheterization and pelvic lavage with silver nitrate is the procedure of choice. Lying on the left side is recommended for gravid

patients. While the interruption of pregnancy affords very prompt relief, it is not recommended. Operative procedures are reserved for complicated cases, such as perinephritic and nephritic abscesses.

P. MEYER.

Bauereisen: A Case of Post-Operative Perinephritis Serosa (Ein Fall von postoperativ entstandener Perinephritis serosa). *Ztschr. f. gynäk. Urol.*, Leipz., 1913, IV, 124.

By Zentralbl. f. d. ges. Gynäk. u. Geburtsh. s. d. Grenzgeb.

In consequence of a Freund-Wertheim operation, an ascending infection took place which followed the lymphatics along the ureter to the renal capsule and gave rise to an inflammation of the tunica fibrosa and fatty capsule including the fascia renalis. The resulting inflammation the author describes as a perinephritis. A secondary invasion of the parenchyma gave rise to a nephritis. The operation of choice is an incision of the kidney. WEISSWANGE.

Baetzner: Contribution to the Study of Pyelitis Granulosa (Beitrag zur Kenntnis der Pyelitis granulosa). *Ztschr. f. urol. Chir.*, 1913, I, 285.

By Zentralbl. f. d. ges. Gynäk. u. Geburtsh. s. d. Grenzgeb.

Baetzner reports a case of pyelitis granulosa which in its clinical manifestations differed from the clinical description of Fritsch in so far as there was no intermittent hæmorrhage. He ascribes this peculiarity to the special pathological findings at operation, to-wit, circumscribed knot-like infiltrations. In the etiology of pyelitis granulosa typhoid plays an important part.

REHN.

Drennen: Traumatic Hydronephrosis. *Ann. Surg.*, Phila., 1913, LVII, 879.

By Surg., Gynec. & Obst.

After distinguishing between three groups of traumatic hydronephrosis, i. e., (1) true traumatic hydronephrosis; (2) pseudotraumatic hydronephrosis; (3) ruptured hydronephrosis, according to Legueu, the author describes the true traumatic hydronephrosis and reports a case of the same.

As the origin of true traumatic hydronephrosis he gives the following etiological factors: Traumatic injuries to the ureter which complicate the renal injury and are invariably situated high up near the origin of the ureter, which may be either ruptured or contused or even completely severed and thus the cause of a cicatricial stenosis or occlusion at the point of injury. A blood-clot in the ureter following injury to the kidney, is another cause. This clot may cause obstruction and produce dilatation of the renal pelvis. The increased pressure above would necessarily distend the ureter so that the arrested urine would find its way alongside the clot, which, occasionally, would sooner or later become detached and washed away. There are also secondary causes such as traumatism, which may lead to floating kidney and this in turn to obstruction of the ureter. A blow over a calculous kidney may dislodge a small stone, which may be impacted in the ureter and thus form a true traumatic hydronephrosis.

Symptoms of true traumatic hydronephrosis, as he states, simulate mostly congenital cystic kidney. In most of the cases hæmaturia is present. The size of the hydronephrotic sac varies according to the nature of the ureteral obstruction, which, when sudden and complete, may produce a small tumor.

The author bases the diagnosis of true traumatic hydronephrosis on the preceding traumatic history and clinical symptoms, such as a fluctuating tumor, retroperitoneal in position, originating in the kidney and developing insidiously, its contents consisting of more or less altered urine.

The differential diagnosis is based on the conditions in which a renal tumor is found; viz., hæmatonephrosis, pyonephrosis, pseudotraumatic and ruptured hydronephroses. According to him, a correct diagnosis is made at operation or autopsy, when the following features are found: The expanded pelvis, the swelling being a true tumor of the pelvis of the kidney; the dilated calices; the flattened papillæ of kidney tissue and the obstruction in the ureter. Also the X-ray may be employed in the correct diagnosis of true traumatic hydronephrosis. A case is reported in detail. J. RADDÄ.

Aleman: A Case of Right-Sided Intermittent Hydronephrosis Caused by Two Accessory Renal Arteries; Operative Removal of Same; Recovery (Ein Fall von rechtseitiger, intermittierender Hydronephrose, hervorgerufen durch zwei Arteriæ renales accessoriæ; Operation mit exstirpation dieser Gefässe; Genesung). *Nord. med. Ark.*, 1912, xlv, No. 10.

By Zentralbl. f. d. ges. Gynäk. u. Geburtsh. s. d. Grenzgeb.

The author reports a case of intermittent hydronephrosis in which two accessory renal arteries were found to be the cause. After operative removal of these abnormal vessels the patient made a full recovery.

HOHMEIER.

Tennant: The Cause of Pain in Pyelography with Report of Accident and Experimental Findings. *Ann. Surg.*, Phila., 1913, lvii, 888.

By Surg., Gynec. & Obst.

Tennant issues a warning relative to the damage which may result to the kidney parenchyma by injection of solutions without accurate control of pressure in pyelography for diagnostic purposes and gives details of one clinical case and of several animal experiments.

In the usual method of injecting collargol through a large-sized ureteral catheter with a piston syringe unconnected with gauge or pressure index the determination of pelvic capacity is left wholly to the symptom of renal colic expressed by the patient. Damage to the kidney may result before the patient complains of colic irrespective of whether water or a preparation of silver has been injected.

The accurate determination of both the quantity of fluid and the pressure can be determined by attaching mercurial blood-pressure manometer to one end of a Y tube while the fluid is discharged

under pressure from a graduated glass cylinder. The recently published method of Thomas for distention of the renal pelvis is a simpler and more practical method where gravity is sufficient.

A female, aged 24 years, presenting symptoms suggestive of chronic appendicitis was found to have complete transposition of viscera and the renal pelvis were injected by means of a piston syringe, with a 15 per cent collargol suspension for diagnostic purposes. The right pelvis received 20 cc. and the left 16 cc. Considerable pain followed but the skiagrams were unsatisfactory. Five weeks later injection of 12 cc. on right and 10 cc. on left of a 25 per cent suspension.

Skiagram showed normal left pelvis and large irregular right pelvis with marked shadow well out in parenchyma extending from center of the right kidney, infiltrating into its upper pole. This shadow was supposed to be a diseased area and exploratory operation was undertaken two weeks later. A large wedge-shaped area of kidney substance about two inches wide was found to be infiltrated with the collargol and the capsule covering this infarct was lifted from the parenchyma by a layer of collargol. The infarct extended to the renal pelvis but was excised without opening into latter. Patient recovered with relief of symptoms.

On microscopic examination, the tubules were found to contain collargol throughout their entire length and extending into the glomeruli. Collargol from both injections was probably present. The tubular epithelium generally was completely necrotic.

In a series of experiments on freshly removed hogs' kidneys it was found that a similar extension of the collargol into the tubules occurred at a pressure varying from 40 mm. to 8 mm. mercury and upward.

J. B. CARNETT.

Warischtschew: Decapsulation of the Kidney (Zur Frage der Nierendekapsulation). *Chir. Arch. Weljaminsowa*, 1913, xxix, 250.

By Zentralbl. f. d. ges. Chir. u. i. Grenzgeb.

The patient was a woman 37 years of age with chronic nephritis, œdema, albumin 1.3 per cent, hyaline and granular casts. First the right kidney was decapsulated. No improvement followed. After 11 months the left kidney was decapsulated. After temporary improvement there was a relapse and 2 years and 7 months after the second operation the patient died.

Contrary to other authors, the writer found in place of the removed capsule a thick, firm, fibrous tissue capsule that produced a complete pressure atrophy of that part of kidney. There was no anastomosis with the renal vessels. The kidney picture was that of secondary contraction. The author concludes from this case that nothing is to be gained by decapsulation in uncomplicated cases of nephritis. The procedure, according to Parlauecchio and Flörken, is indicated only in exacerbations of nephritis, in uræmia and in anuria. Eclamps-

sia is a special indication for decapsulation, but a secondary contraction due to the formation of a fibrous tissue capsule may occur in any of these cases. The author's experience corresponds to the experiments of Rosoff, who also found sclerotic changes in the newly formed vessels. The author agrees with Israel in considering decapsulation an unfavorable procedure.

HESSE.

Moore and Corbett: An Experimental Study of Several Methods of Suturing the Kidney.
Ann. Surg., Phila., 1913, lvii, 860.

By Surg., Gynec. & Obst.

The authors point out that the damage resulting from suture of the kidneys is much more extensive than from the incision and is, moreover, very variable, ranging from slight scar tissue formation to complete destruction of the parenchyma. Where mattress sutures are used, small portions of the kidney substance may be strangulated, especially in the pyramids. Later calcification with the formation of a calcium phosphate stone may occur. This was produced experimentally, the stone forming in three months.

After reviewing the anatomy of the blood supply, the authors consider the question of methods of incising the kidney, and state their objections to the silver-wire method of Cullen. They give the results of a series of experiments on animals in which the knife and wire were used: the authors found the wire produced as great if not greater areas of infarction and more damage to the collecting tubules which at times do not run parallel to the vessels in the parenchyma. They found that if Carrel soft-jawed forceps were applied to the renal vessels to control immediate bleeding, and the kidney opened with a sharp knife, avoiding the poles, the least damage was done. After the necessary exploration the parenchyma is approximated by "through and through" sutures of very fine silk.

Kidneys sutured by them in this way do not bleed and they show by a considerable number of experiments that the temporary compression of the renal vessels produces slight desquamative or fatty changes only. Kidneys examined a few weeks after simple clamping of the vessels were normal. Further experiments showed that the clamping of renal vessels for one hour had no serious effect on renal function. Their conclusions are that, while mattress sutures of any material cause extensive destruction of kidney substance, "through and through" sutures with fine silk produce but slight lesions.

HORACE BINNEY

Läwen: Concerning Bilateral Ureterolithotomy in Calculous Anuria (Über doppelseitige Ureterolithotomie bei calculöser Anurie). *Beitr. z. klin. Chir.*, 1913, lxxxiv, 411.

By Zentralbl. f. d. ges. Gynäk. u. Geburtsh. s. d. Grenzgeb.

Most writers assign very minor importance to ureterolithotomy in calculous anuria as compared with operation (nephrotomy) on the affected kidney.

They concede this procedure permissible only under special conditions. They hold removal of a stone a secondary matter. Double sided ureterolithotomy is even more seldom carried out. In conjunction with a case in which this procedure was successfully performed the author discusses the indications and prognosis of this operation. It is indicated in impacted stone in the iliac or pelvic portion of the ureter, but adaptable only if the pelvis is otherwise free from stone. In cases of unprotracted anuria it is best to attempt to dislodge the stone first by ureteral dilatation or injection of an indifferent fluid. In event of a severe anuria it is necessary to perform a single or double nephrotomy for it favors the re-establishment of the renal function as does an intestinal fistula in ileus. The proportion of cases in which bilateral ureterolithotomy is indicated is very small but its range of usefulness will broaden.

OEHLEK.

Hartmann: Operative Treatment of Supernumerary Aberrant Ureters (Zur Kasuistik und operativen Behandlung überzähliger aberranter Ureteren). *Ztschr. f. Urol.*, 1913, vii, 429.

By Zentralbl. f. d. ges. Chir. u. i. Grenzgeb.

A thirty-three year old female patient had been consulting several physicians for nocturnal enuresis without getting relief, when Hartmann discovered a small opening below the orificium externum urethrae from which a little drop of urine was passing when the patient coughed. Further examination revealed the opening as the outlet of a supernumerary aberrant ureter. By the vaginal route this ureter was then implanted into the bladder and the patient was relieved of her trouble.

The author collected fifteen cases of supernumerary aberrant ureters from literature; there were twelve other cases in which it was not possible to decide whether they dealt with supernumerary aberrant, or with perfect, ureters, and finally seven cases of perfect ureters with abnormal outlet. It is often extremely difficult to find the narrow opening. Sounding is almost always impossible. As operative methods, implantation of the ureter into the bladder or into the urethra may be considered; for implantation into the bladder the vaginal, the transvesical or abdominal route may be chosen. The vaginal implantation into the bladder is the method of choice.

RUBRITUS.

Hutchinson: Obstruction of the Ureter by Aberrant Renal Vessels; a Clinical Study of the Symptoms and Results of Operation.
Proc. Roy. Soc. Med., 1913, vi, Surg. Sect., 201.

By Surg., Gynec. & Obst.

To insure an early diagnosis of vascular obstruction of the ureter, Hutchinson notes the following signs: It is found generally in males, usually between the age of 15 and 25, rarely younger. The attacks of pain are periodical with an interval of months or years between the early ones, while the later ones come on every week, or oftener. Finally,

when the pelvis dilates permanently, the attacks cease, only a dull pain in the loins remaining. The pains are severe, doubling the patient up and making him sweat profusely. Vomiting is frequent, although it does not always occur. The pains are located chiefly in the lumbar region, but may occur in the front of the abdomen, and radiate toward the groin and testes of the same side, rarely into the shoulder. It is one-sided, occurring on the right side twice as frequently as on the left. Relief is obtained by lying on the affected side. Neither medicines nor aperients are of use.

Exertion does not cause the pain as a rule. It may come when patient lies down; it is not affected by diet, time of meals, nor constipation.

There are no objective signs. Cystoscopy may show congestion of the ureteric orifice on the affected side. A skiagram will make the diagnosis.

Urinary symptoms are absent; there is no frequency of micturition during or after an attack. Occasionally hæmaturia, traces of albumin and pus are present. The cause is congenital. It is not dependent upon a floating or a too mobile kidney.

In the majority of cases lumbar exploration alone is required. The vessel or vessels at fault are ligatured and excised. A plastic operation has been performed in cases with distortion of the pelvis but without success. The author claims it is best not to open the canal but to straighten out the pelvis and ureter as far as possible. He advises early operation.

LOUIS GROSS.

Ottow: Contribution to the Study of Intermittent Ureterocele Vesicalis (Beitrag zur Kenntnis der intermittierenden Ureterocele vesicalis). *Ztschr. f. gynäk. Urol.*, Leipzig., 1913, iv, 103.

By Zentralbl. f. d. ges. Gynäk. u. Geburtsh. s. d. Grenzgeb.

The author describes a case of unilateral ureteral prolapse the size of which varied with the strength of the urinary stream. It was plainly at its greatest size during action of the ureter, and diminished in the intervals. This observation made it clear to the author that the action of the ureter is the explanation of the well-known variability in size and appearance of such a ureterocele.

HOLZBACH.

Lohnstein: Cystic Dilatation of the Vesical End of the Ureter (Cystische Erweiterung des vesikalen Ureterendes). *Ztschr. f. Urol.*, 1913, vii, 517.

By Zentralbl. f. d. ges. Chir. u. i. Grenzgeb.

The author describes a case of ureterocele successfully operated by him three years ago by the endovesical route. The patient was a woman, 29 years old, who had suffered for many years severe pains in the lower abdomen. She had had an appendectomy, a double ovariectomy and a vaginofixation performed without relief. At the present time she complained of acute bladder catarrh. Cystoscopic examination showed the bladder wall bulged inward by the ureterocele; the mucosa surrounding the ureteral opening was prolapsed. Diagnosis: right-sided ureterocele. At operation the prolapsed

mucosa was cauterized with a Loewenhardt cautery introduced through a cystoscope. The ureteral opening immediately enlarged; bulging of the bladder mucosa disappeared. The patient's symptoms entirely ceased. The author in operations of this kind prefers the endovesical route.

OEHLEK.

Zuckerkancl: The Local Treatment of Retention of Urine and Pus in the Kidney by Means of Ureteral Catheterization (Über die örtliche Behandlung renaler Harn- und Eiterstauungen durch Harnleiter-katheterismus). *Wien. med. Wchnschr.*, 1913, xxii, 1345.

By Zentralbl. f. d. ges. Chir. u. i. Grenzgeb.

Normally there is no urine in the renal pelvis. Residual urine in the kidney pelvis must be looked upon as a pathological condition. Complete or partial retention, whether aseptic or infected, can be therapeutically influenced by the introduction of ureteral catheters even though in many cases it may be only a palliative measure. Where the urinary retention in the kidney is complete, the severe symptoms of the attack, as seen in intermittent hydronephrosis, can usually be relieved quickly by evacuation of the urine by means of the ureteral catheters. The duration of the disease cannot be limited by the catheterization since in cases of complete retention in the renal pelvis pressure atrophy of the kidney tissue appears after a short time.

The therapeutic benefits of ureteral catheterization are more marked in cases of chronic incomplete retention, and especially in the infected forms. Besides catheterization, lavage of the renal pelvis may have to be considered. On account of hæmorrhage, pain, etc., the catheters cannot be retained indefinitely, usually not longer than 24 hours. Each case must be examined with due regard for all the symptoms, and the anatomical and pathological relations accurately determined by all the modern methods. In all cases of disease of the perirenal or renal tissue, and in those with marked constitutional disturbances immediate operation is indicated. OEHLECKER.

Pakowski: Permanent or Temporary Derivation of the Urine by Means of Nephrostomy (La néphrostomie moyen de dérivation permanente ou temporaire des urines totales). *Thèse de doct.*, Par., 1913, June.

By Journal de Chirurgie.

The indications for urinary derivation are multiple; such as, severe tuberculous cystitis, painful and inveterate cystitis, bladder tumors, exstrophy of the bladder, pelvic cancer pressing on the ureters, obstinate vesico-vaginal fistulæ; and some cases of renal lithiasis. The incision must be short, so as not to require many stitches to repair it; the fistula must be made on the lower calyx; and the drain must be well secured in correct position. When the derivation is intended to be permanent the best way to occlude the ureter is to pleat it, accordion fashion, by means of a stout catgut. Around each suture thread and on each lip of the incision, a zone of necrosis $\frac{1}{5}$ to $\frac{1}{3}$ of an inch thick is produced. This

is far from the necrosis of $\frac{1}{3}$ or even $\frac{1}{2}$ of the parenchyma wrongly maintained by some authors.

Far from impairing kidney function, fistulization improves it, as demonstrated conclusively by many cases. In some instances the improvement is such that radical surgical interference may come up for consideration later. If, besides, we take into account the fact that there exist a number of perfectly tight appliances to collect the urine, we must admit that nephrostomy deserves a greater place in practical work than it has been heretofore granted.

GASTON PICOT.

Kidd: A Small Muscle-Splitting Incision for the Exposure of the Pelvic Portion of the Ureter.

Lancet, Lond., 1913, clxxxiv, 1578.

By Surg., Gynec. & Obst.

The author bases this report on his experience in the dissecting room, and on a series of operations on the living. He advocates an incision three inches in length parallel to Poupart's ligament and one and one half inches above it, the center of the incision being directly over the internal abdominal ring. The various layers of muscles are divided in the direction of their fibers; more room is secured by the inward retraction of the rectus muscle, great care being used not to cut its posterior sheath. The ureter is to be exposed at the point where it crosses the external iliac artery. The author claims the following three advantages for the incision: that it avoids injury to the last dorsal and ilio-hypogastric nerves and to the deep epigastric vessels, and prevents the occurrence of post-operative hernia.

HENRY L. SANFORD.

BLADDER, URETHRA, AND PENIS

Lewis: Where is the Fundus of the Bladder? J.

Am. M. Ass., 1913, lx, 1765.

By Surg., Gynec. & Obst.

In an appealing communication, Lewis asks that the term fundus of the bladder, which in truth has origin from the Latin, in meaning the base, be corrected. It is a misnomer, inasmuch as the term as applied has reference to the vertex. He asks that the nomenclature be changed, according to the true anatomy of the part and the classification as given by the anatomists, as follows: (1) The summit or vertex; (2) the base or fundus; (3) the body; (4) the cervix or neck.

IRWIN S. KOLL.

Unterberg: The Operative Treatment of Rebellious Cystitis Cases with Curettement of the Bladder and Temporary Urinary Fistula

(Die operative Heilung der rebellischen Cystitiden mittelst Blasencurettag und zeitweiliger Blasen fistel). *Beitr. z. klin. Chir.*, 1913, lxxxiv, 251.

By Zentralbl. f. d. ges. Gynäk. u. Geburtsh. s. d. Grenzgeb.

The author defines as rebellious, cases of chronic cystitis in which deeper pathological changes prevent or interfere with the return of the organ to normal. He divides the disease into two types, one

in which definite anatomical changes of the mucous membrane exist, such as ulcerous cystitis, leucoplacia, cystitis pseudomembranosa; and the other without characteristic mucous membrane changes. The etiological factors are gonorrhœa, pregnancy and catheterization. Anatomically the severe bladder lesion consists of a thickening and induration of the individual layers, which decrease the mobility and dilatability of the organ and convert it into one of fixed capacity. As the most severe changes occur in the submucous layer, curettement of the focus is necessary.

According to the author the entire removal of the mucous membrane through a suprapubic opening, with prolonged drainage and irrigations with 1-3 per cent silver nitrate solution, is the most thorough method. If the patient is a woman and refuses a suprapubic operation the treatment may be performed through the urethra. In very severe muscle degeneration with minimal capacity, the only treatment consists in performing a permanent, easily closing urinary fistula to liberate them from the continuous desire to urinate. He reports seven cases of personal observation and treatment (six women and one man). Of the three cases in which the bladder curettage was performed through the urethra, two were improved, and one had a recurrence after a short improvement. Two cases of suprapubic curettement with temporary fistula were decidedly improved. Two cases with suprapubic curettement and permanent fistula were not improved on account of the extensive destruction of the bladder musculature. The best results are obtained *sectio alta* and curettement. Local treatment produces no results in rebellious cystitis.

DORN.

Lerda: Contribution to the Treatment of Exstrophy of the Bladder

(Contribution au traitement de l'exstrophie de la vessie). *J. de chir.*, 1913, x, 549.

By Surg., Gynec. & Obst.

The author groups the various methods of treatment of exstrophy of the bladder as follows:

1. Interventions having in view the reconstruction of the bladder and urethra.
2. Interventions upon the ureters to avoid the inconveniences caused by the mucosa of the exstrophied bladder and to limit the escape of urine.
3. Interventions having in view the deflection of the urine into the intestine.

4. Interventions having in view the creation of a vesical pouch possessing an orifice to the exterior, placed under control of the sphincter ani, and without any connection with the rectum.

After a brief review of the technique involved in these methods of treatment with their advantages and dangers, Lerda evolved a principle which resolved itself into two steps:

1. To obtain a closed vesical pouch, no matter how small, use entirely or in part the exstrophied wall since this wall is most apt to fulfill bladder function.

2. To create to this cavity a vesico-perineal canal for the escape of urine, independent of the intestine but passing within the ring of the sphincter ani.

This principle was applied in the following case: A boy, aged six and one half years, with exstrophy of the bladder with epispadias, had been operated upon a year previously. The operator had succeeded in creating a small vesical cavity with a hypogastric orifice. This orifice was on the pubic eminence, had scar tissue margins, was circular and admitted one finger. The epispadic penis was likewise scarred, due to an unsuccessful attempt to construct a urethra. Scrotum empty, undescended testicles in the inguinal canal.

The operative procedure was as follows: 1st step. In the perineo-scrotal region a longitudinal skin flap, 8 cm. long by 4 cm. wide, was dissected up with a thick base at the anal orifice. The sphincter ani was next carefully exposed and separated from the anterior wall of the rectum. A large Hegar dilator was introduced into the rectum in order to displace it forward and upward and force the small intestines out of the pouch of Douglas. Then with one finger in the bladder a blunt director was forced into the tissues between the sphincter ani and the rectum into the cellular pelvic tissue and a retro-prostatic canal made to the base of the bladder. Next, the end of the skin flap was grasped in a curved forcep and introduced as a posterior and lateral lining for the canal. As yet the bladder was not opened. In order to epithelialize the rest of the canal, one large Thiersch graft was wrapped around an ordinary T glass fenestrated drainage tube. The graft was punctured over the fenestra of the tube in order to permit the escape of blood. With one finger in the bladder this tube was carefully introduced into the new canal and retained in proper position by a suture at its perineal end. The defect in the perineum was closed. At the end of eight days the tube was withdrawn and in order to make sure that the epithelialization of the new canal was complete a new tube covered by a Thiersch graft was introduced.

2nd step. Eight days after the second graft a curved metal sound was introduced through the canal to the base of the bladder in the median line and the bladder was incised. A large Petzer catheter was passed from the bladder to the perineum. This catheter collected about fourteen ounces of urine a day, the rest escaping through the anterior orifice of the bladder because of the undue prominence of the interureteral ligament.

3rd step. After some weeks, during which the retention catheter had been frequently changed and the vesical orifice firmly established, an attempt was made to close the anterior orifice of the bladder by freshening its surface and utilizing the epispadic tubercle of the penis as an inverted U flap. The sutures held for the most part and the small fistula which persisted healed slowly under permanent drainage through the perineal meatus.

The patient was kept under observation for

several weeks. After the withdrawal of the retention catheter it was noticed that during the effort of defecation a few drops of urine escaped by the vesico-perineal canal, but the bladder was not continent and the tonicity of the sphincter in regard to continence of fæces was the same as before the operation. The patient was allowed to go home but returned very shortly with a suprapubic fistula, which was discovered to be due to a stricture of the newly formed canal, which would hardly permit the passage of a filiform. This stricture was dilated until it permitted the passage of a No. 28 sound. The tendency toward stenosis at the vesical extremity of the newly formed vesico-perineal canal is the weak point in the author's technique because it has a tendency to recur and must be kept dilated with sounds.

Almost a year has elapsed since the operation. The patient returns for periodic dilatation of the canal, which permits the entrance of a No. 28 sound. There is relative continence of the bladder; mornings, when he wakes, in pressing as for defecation he emits, in a stream, a quantity of urine varying between 150 and 200 cc. The amount of urine collected during the day is much less but the capacity of the bladder is 300 cc. During the day there escapes from the perineal orifice enough urine to oblige the patient to carry an apparatus for its collection. This is due to the weakness of the sphincter ani muscle. If this weakness does not improve the author intends to perform one of the usual operations for improvement of tone of the sphincter.

The author concludes that of all proposed methods for the treatment of exstrophy of the bladder, the only ones worthy of consideration are those which have in view the formation of a closed vesical cavity with a communication to the exterior under the control of the sphincter ani. Methods which utilize for this purpose any part of the digestive tract are too grave. Those which construct in the anal sphincter an entire segment of intestine weaken the already feeble sphincter ani too much to be effective. The methods which create an intra-sphincteric tube by means of a segment of the anterior wall of the rectum are too grave and too difficult because the operative field does not lend itself to the numerous sutures which are necessary. There is also the difficulty of excising enough of the rectal wall without producing a stenosis.

In most cases there exists a flap of vesical wall thick enough and wide enough to be utilized for the creation of a urinary reservoir. This reservoir, no matter how small, can be dilated enough to be serviceable; for this purpose the dilator invented by Nota is recommended.

In order to furnish a canal for the escape of urine, from the reservoir it is not necessary to resort to extensive plastics at the expense of the bladder or digestive tract, since a cutaneous plastic made from flaps of the perineum, completed by Thiersch grafts, can perfectly fulfill the conditions.

ELLIS FISCHER.

Oppel: Exclusion of the Bladder (Die Ausschaltung der Harnblase). *Arch. d. chir. Klin. d. Prof. Oppel*, St. Petersburg, 1913, iv, 3.
By Zentralbl. f. d. ges. Chir. u. i. Grenzgeb.

The author reports twenty bladder exclusion operations performed in his clinic according to the method of Mirotworzeff. The ureters, after being liberated, were divided as near to the bladder as possible and implanted into the pelvic colon or into the lower sigmoid. The ureter stump was placed into an opening made in the bowel, mucosa being sutured to mucosa and reinforced by a second row of sutures. In the first row of sutures it was advisable to include the adventitia of the ureter to prevent the sutures from tearing out. The operation was performed for exstrophy and for carcinoma of the bladder (in the latter as a preliminary procedure), for high epispadias with a cleft sphincter, for vesicovaginal fistula in which a plastic operation proved unsuccessful and finally as a palliative procedure in inoperable carcinomata and severe tuberculous infection of the bladder.

In exstrophy of the bladder he author discarded the methods of Maidl and Ssubotkin, since they are accompanied by too high a mortality. Of eight cases operated according to the method of Mirotworzeff, two died, both under 7 years. The bladder itself was not removed until two weeks after its exclusion. In carcinoma of the bladder cystectomy was performed twice in the author's clinic after a previous exclusion according to Mirotworzeff.

The author collected ten cases from the literature, in six of which the urine was led externally and in the remaining four was led into the bowel. No deaths occurred among all these cases. The implantation method of Mirotworzeff, however, is to be preferred, since it does away with the agonizing urinary fistula. With the good results obtained in the two-stage bladder extirpation for carcinoma, the indications for this operation must be extended at the expense of resection in which poor results are obtained.

A well-functioning sphincter and a necessary condition for the operation. The condition of the kidneys also is important; advanced nephritis and pyelitis are contra-indications. A third contra-indication is youth; children under 10 years offer a high mortality. In conclusion Oppel asserts that although affections which indicate exclusion of the bladder are necessarily accompanied by danger of ascending infection, this is not so great, according to his experience, after operation as is generally supposed. In a series of his patients symptoms of unilateral or bilateral pyelitis set in shortly after operation, but they again disappeared after a time. Those patients who previously had perfectly healthy urinary tracts reacted more intensely, which must be attributed to an absence of local immunity. To minimize the danger of infection the author advises free catharsis and disinfection of the bowel, and immunizing the patient against the colon bacillus. In his last cases the author observed good results with

milk diet and with the ferment regulatic Chiari on the one hand and polyvalent coli vaccine on the other. In regard to the latter question a dissertation by Iljin will appear later. **RIESENKAMPFF.**

Buerger: A Clinical Study of the Application of Improved Intravesical Operative Methods in Diagnosis and Therapy. *Med. Rec.*, 1913, lxxxiii, 1114.
By Surg., Gynec. & Obst.

The author gives a detailed description of his instruments for intravesical operations. The many conditions in which these are of value are then discussed and cases cited in connection with each. Exploratory excision in suspected carcinoma of the bladder or prostate has been of great assistance in forming a diagnosis not only as to the presence or absence of carcinoma but also, if present, as to its probable source. Removal of other suspected vesical lesions is of diagnostic value and sometimes the simple removal results in a cure. Calculi can often be removed with the author's small instruments.

Dilatation of ureters is of service when there is a real stenosis of the ureter or in cases of ureteral calculi where the passage of the stone downward has been arrested. Renal tuberculosis can often be diagnosed from the microscopical examination of small vesical tubercles when no other definite sign of tuberculosis of the renal system can be determined. **J. H. SKILES.**

Hirsch: The Effect of Gonorrhœal Infections upon the Musculature of the Genito-Urinary Tract. *Am. J. Urol.*, 1913, ix, 283.
By Surg., Gynec. & Obst.

Author discusses the secondary symptoms produced by infiltrations and fibrous deposits in the genito-urinary muscles. He states that the so-called spasmodic stricture may be due to a swelling of the mucous membrane, or to muscular contraction, which again has to be classified as the inhibitory action of the bladder wall and the actual spasm of the urethral muscles. The close proximity of the ampulla and seminal vesicles to the bladder may induce, in their infected state, frequent bladder contractions, so-called bladder irritability and chronic cystitis, without causative evidences in the upper urinary tract. This condition is promptly relieved by emptying the seminal vesicles. **HARRY KRAUS.**

Pedersen and Cole: Mensuration and Projection of the Posterior Urethra and Vesical Floor by Means of Posterior Urethral Calipers and Radiography. *N. Y. M. J.*, 1913, xcvi, 1273.
By Surg., Gynec. & Obst.

To ascertain the exact position of the outlet of the bladder, the authors devised a new instrument of the catheter type, so that the bladder may be filled to moderate distention. When withdrawn until the flow ceases, the instrument occupies the exact outlet with the conical head, thus avoiding the uncertainties incident to the solid non-catheterizing instruments. This new instrument has a head 1 cm. long, mounted

on a 10 F. flexible copper catheter, of which the vesical outlet is 0.5 cm. back from the base of the head at the mid-point of a space 1 cm. long. This is followed by a smaller olive-form head, also 1 cm. long. Thus, when the conical head is in the bladder cavity at the neck, the outlet of the catheter will be closed by the sphincter muscle and the olive-form head will be about 1 cm. distal to the sphincter. To avoid the alteration of the shadow of the bladder and its relation with the upper margin of the symphysis, they had the cone of the tube carrier at a right angle to the table and its edge tangent either to the base of the penis in males, and clitoris in females, or to the upper limit of the symphysis, which is seemingly the appropriate position, as indicated by palpation.

The authors claim that the separation between the bladder shadow and the symphysis may be due to the opening up of the prevesical space through the weight of the distending fluid while the patient is in the recumbent position. This is important in dealing with X-ray work on the bladder. Another essential point is the position of the sphincter, as in the male it carries with it the upper surface or base of the prostate. The third important point for determination is the location of the apex of the prostate as the gland surrounds the posterior urethra. Calculi and other conditions somewhat discernible by the X-ray are in this portion of the gland and urethra. To locate the apex of the prostate they passed a small flexible bougie-à-boule alongside the catheter, not always with success, as the head was so small and frequently not between the finger and catheter, that it escaped detection in the bulb of the urethra and was thus advanced too far. They were not successful with an ordinary bougie-à-boule, 24 F., curved to agree with the standard sound inserted into the bladder and withdrawn until its head seemed to lock on the sphincter. Over its shaft was passed a blunt uterine curette with its point bent at right angles to its shaft, which was likewise slightly curved on the same radius. This large loop was easily advanced along the urethra and unmistakably felt in the bulb at the apex of the prostate. For accuracy in radiography of the pelvis, they use the transverse diameter of the true pelvis which passes approximately through the spines of the ischia at their bases. The advantage of this imaginary line is that it is slightly posterior to the position of the ureters. Many lesions begin on the floor near the ureters, and tumors of the prostate occur above the ureters first and foremost. There is usually a slight pouching of the bladder beyond this line; therefore the shadow of a stone in the bladder would be in this line, if the bladder is reasonably normal; above it, if there is much pouching, and below, if the bladder floor has been altered by operation.

J. RADDA.

Silva: The Comparative Value of Cystostomy and Urethrostomy in Operations on the Urethra.
Am. J. Urol., 1913, ix, 277. By Surg., Gynec. & Obst.

Silva lays stress upon the importance of diversion of the urine in all operations upon the urethra where

the urinary flow is likely to contaminate the operative site and interfere with primary healing of the wound. The former method of treatment of perineal urinary fistula by cauterization always failed. Equally unsuccessful were the attempts to cure by excision of the fistulous tract and introduction of a catheter. Prof. Marion now treats all cases of urethral fistula by diversion of urine. The author has notes of twelve cases which showed rapid and perfect cure, although some of them had been previously operated upon unsuccessfully.

Diversion of urine in operations for penile fistula and for well-limited perineal fistula is best done by a temporary urethrostomy behind the closed fistula. Where there are multiple fistulae (the so-called watering-pot perineum), supra-pubic drainage should be used. In all operations for hypospadias, save, possibly, in the Hacker-Beck operation for glandular hypospadias, diversion of the urine is essential for success. Diversion of the urine is likewise an important step in operations done for traumatic rupture of the urethra. The writer reports three such cases operated upon by Heitz-Boyer.

Silva describes an operation for hypospadias, dividing the operative technique into four steps:

1. The freeing and straightening of the penis.

Two months later the second step is carried out.

2. Resection of the new urethra.

3. Urinary diversion.

4. Closure of the abnormal meatus. This step is undertaken two months after cicatrization is complete, and it is advisable to again do urinary diversion.

ABE NELKEN.

GENITAL ORGANS

Schmutz: Comparative Study on the Treatment of Acute Gonorrhœal Epididymitis with Antimeningococcic Serum (Traitement des épididymites aiguës blennorrhagiques par le sérum antiméningococcique; étude comparée). *Thèse de doct.*, Par., 1913, June.

By Journal de Chirurgie.

This treatment is justified by the morphological and biological affinities of the gonococcus and meningococcus. From the study of 52 cases, the writer draws the following conclusions: Pain is promptly relieved, as early as the second or third hour after the injection. The injection sometimes causes a temporary rise in temperature, but the latter is followed by a marked fall. The acute inflammatory symptoms and the oedema subside in 24 or 36 hours; the effusion in the tunica vaginalis, if any, undergoes resorption, sometimes in 48 hours, but more often in 5 or 6 days. The infiltration of the epididymis yields more slowly, a decrease in volume being noticeable only after 3 or 4 days. All induration disappears in from 10 to 18 days.

Six patients were seen a few weeks after the treatment; in five the epididymis was perfectly normal; in one a slight node persisted. The patency of the epididymis could not be tested, but, judging from the perfect anatomical restitutio ad integrum, it is very probable.

One injection (20 cc.) is often enough; more than three are required only in exceptional cases. No anaphylaxis phenomena were ever noted. This method is far superior to all other treatment, either by operation, hyperæmia, injection of colloidal silver or of vaccines. The injection of antigonococcic serum alone can compare with it. GASTON PICOT.

Barney: Tuberculosis of the Epididymis: Its Effect upon Testicles and Prostate. *Boston M. & S. J.*, 1913, clxviii, 923. By Surg., Gynec. & Obst.

In two previous articles the author contended that the prostate was the focus in tuberculosis of the male genital tract. In the present paper, illustrated by two charts, Barney overthrows his previous contention and shows conclusively that the primary focus is to be found in the epididymis in the vast majority of cases. The rôle of the prostate in the symptom-complex is carefully considered.

In making a plea for more light on this perplexing question Barney quotes the words of Hallé and Motz.

"An integral mass of statistics, patiently followed up, on pulmonary tuberculosis on the one hand, and on genito-urinary tuberculosis on the other, from the earliest clinical side of the patient to the ultimate issue will furnish sufficient and certain conclusions. We do not yet possess such a mass of statistics."

He also strongly emphasizes the futility of removing the testicle in the belief that cure is more likely to follow. Except in rare cases epididymo-vasectomy is the operation of choice.

The writer's conclusions are as follows:

1. In genital tuberculosis, the epididymis is the primary focus in the vast majority of cases.

2. Tuberculosis of the epididymis becomes bilateral in 41.6 per cent of all cases, and becomes so within six months of the time of involvement of the first side in 30 per cent.

3. The prostate and vesicles are found to be infected in 75 per cent, this infection occurring in the first six months in 30 per cent and in the first year in 54 per cent. It is also shown that this infection takes place quite as often in the presence of unilateral, as of bilateral, epididymitis.

4. The urine is pathological in 43 per cent of all cases; bladder irritability is found in 35 per cent and in about half of these it occurs in the first six months.

5. In 33 per cent tuberculosis, past or present, of organs other than those of the genito-urinary tract is to be expected. The lungs are most often attacked.

6. Clinical observation shows tuberculosis of the testicle in 44 per cent, but the pathologist finds the disease in 66 per cent, and of these 53 per cent are found infected within six months of the onset of the epididymitis.

7. The records of 67 epididymectomies show that no case has yet returned for orchidectomy. The radical operation is, therefore, rarely necessary.

8. Infection of the first and second epididymis, as well as of prostate and vesicles, seems to be by the

blood or lymphatic streams, but it cannot be denied that in some, infection takes place through the vas by an ascending or descending process.

9. The operative mortality of 147 cases is 2.72 per cent, a general miliary tuberculosis being the most common cause of death.

10. As it has been shown that the infection may become widespread in the first six months of the disease, operation at the earliest possible moment is strongly indicated.

Bissel: Restoration of the Bladder Function after Prostatectomy. *Internat. J. Surg.*, 1913, xxvi, 193. By Surg., Gynec. & Obst.

The removal of the enlarged prostate is a comparatively easy procedure. Many attending conditions, however, may be much more difficult to treat. Distention of the bladder, changes in the mucous membrane, sacculations, paralysis of the bladder, musculature changes, altered relation of the muscle insertions, hypertrophy of the vesical wall followed by dilatation, the formation of stone, and even the growth of tumor, not to mention the cystitis with resulting inflammation of the ureters, pyelitis and the usually fatal nephritis following it, are some of the consequences arising from disease of the prostate and bladder.

The restoration of the bladder function is a very important part of the after-treatment of prostatectomy. A bladder which has long been over-distended usually contains foul residual urine and has an accompanying cystitis. Such a bladder does not regain its normal size and condition rapidly but only after prolonged treatment does improvement become marked.

The author has a decided preference for the perineal route for prostatectomy. His reasons are that this route favors drainage and allows the formation of a persistent sinus with less discomfort than does the suprapubic route. He believes in treating the bladder after operation with repeated irrigations. Many solutions are recommended but the author prefers either a weak alcohol solution with the addition of a small amount of glycerin or the employment of a weak solution of silver nitrate. In order to be effective these irrigations must be kept up for a considerable length of time and in some cases a permanent perineal sinus seems to give the most comfort.

Internal remedies, such as strychnine or atropine, are usually given. J. H. SKILES.

MISCELLANEOUS

Hess: Experimental Study Concerning Bacillus Coli Infection of the Urinary Organs (Experimentelle Untersuchungen über die Bacterium-coli-infektion der Harnorgane). *Mitt. a. d. Grenzgeb. d. Med. u. Chir.*, 1913, xxvi, 135.

By Zentralbl. f. d. ges. Gynäk. u. Geburtsh. s. d. Grenzgeb.

Injections of virulent cultures of *B. coli* were made into healthy bladders and, in one instance, into a bladder previously irritated by an injection of tur-

pentine oil. In the latter instance there ensued a severe cystitis with marked pyuria. The other cases suffered only a more or less marked bladder irritability or inflammation of the mucosa. Injection into the renal pelvis without hindrance to the urinary stream provoked only a bacilluria with a few leucocytes, but no alterations in the pelvis or the canal-systems. After artificial ureteral constriction generally with a more or less persisting stasis (up to 68 hrs.) severe damage followed, chiefly in the region of the pelvis and upper part of the ureter. The infection was invariably ascending either through the canal or lymphatic systems. Intravenous injection with simultaneous artificial ureteral constriction gave rise to an infection of the ascending type in which the most marked changes were observed in the pelvis. In the unoperated side there were only minor, if any, alterations in the kidney.

In order to test the possibility of bacterial passage through the intestinal wall an artificial ureteral stenosis was produced and opium administered for a long time. No renal infection was demonstrable, cultures from bladder and pelvis being negative. The conclusions are as follows: *B. coli* is an organism pathogenic for rabbits, capable of producing deep-seated lesions in the urinary apparatus, and a factor in concrement production. Of greater importance is urinary stasis, which, even in the presence of most insignificant alterations in the urinary passages, invites infection with the *B. coli* and increases its virulence. The infection corresponds to the ascending type. Descending infection is possible, but infection from the intestine is hypothetical only as long as there is no proof of transmigration of bacteria through the intestinal wall either in conditions that are normal or described as "intestinal disturbances." The preponderance in women affected is due to local conditions (shortness of the urethra) which favor the ascent of the germ. In addition there are a number of contributory conditions, as gonorrhea, loosening of the mucosa in the menses and pregnancy. The unusual incidence in the right kidney is due to the anatomical structure, a predisposition of that kidney to lie abnormally low, in common with visceroptosis. In consequence there occurs a more or less persistent kink which by hindering the normal stream affords the first step in kindling an infection.

MÜNNICH.

Kelly and Lewis: Silver Iodide Emulsion—A New Medium for Skiagraphy of the Urinary Tract. *Surg., Gynec. & Obst.*, 1913, xvi, 707.

By Surg., Gynec. & Obst.

Everyone has found that all of the various media injected for X-ray purposes possess various disadvantages. Collargol is widely used and may be taken as a good example of the group. The chief objections to collargol are: (1) It is dirty and stains everything with which it comes in contact; (2) it is expensive; (3) it is a proprietary preparation.

Harmful results following collargol injection have

been reported from time to time. In two cases operated upon by Kelly in the last few months previously injected with collargol it was noticed that the perirenal tissues were discolored, the collargol having passed through the renal pelvis although the latter was intact. One of these cases required prolonged drainage before healing.

The use of an emulsion of the iodide of silver for skiagraphic purposes was suggested by the fact that it had already been used therapeutically in the bladder by Siter and Uhle. Silver iodide is insoluble in water and must, therefore, be suspended. This is best done in mucilage of quince seed. The preparations put out by different establishments vary a great deal, some being far better than others. Silver iodide is clean; it does not stain; its exact concentration is known and can be controlled. It is bland, stimulating and antiseptic. Its cost is inconsiderable. The silver iodide emulsion generally used by the authors in 5 per cent strength to inject the bladder, ureters or pelvis of the kidney casts a decidedly better shadow than does a collargol solution of equal strength. In fact, 5 per cent silver iodide emulsion in a test tube casts a shadow fully as dense as will a 10 per cent collargol solution. Less concentrated preparations may be employed if the cavity to be injected is of any size; as, for example, if the bladder is being X-rayed. Some have feared that silver iodide emulsion injected into the ureters might precipitate, leaving behind particles which might be the nidus of a future stone, but the authors are convinced that this fear is groundless. They conclude, that silver iodide emulsion carefully prepared in a 5 per cent strength is a safe preparation to use for radiography of the entire urinary tract. It is non-toxic and can safely be used even in large amounts.

Smith: The Excretion of Formalin in the Urine; an Inquiry into the Accuracy of Burnam's Test. *Boston M. & S. J.*, 1913, clxviii, 713.

By Surg., Gynec. & Obst.

Burnam's test consists in adding three drops of 0.5 per cent aqueous solution of phenolhydrazine hydrochloride, three drops of 5 per cent aqueous solution of sodium nitroprusside and then an excess of a saturated aqueous solution of sodium hydroxide. The solution to be tested and the sodium hydroxide must be heated a little above body temperature. Formaldehyde, 1-20,000 or stronger, causes an intense blue which changes to green and then brown. In solutions 1-150,000 up to 1-20,000 the first color is green, going over into brown. Urotropin will not give this reaction. Urotropin may be broken down by acidulating with sulphuric acid and boiling, when the solution will react.

The article outlines the work of determining the conditions under which the test is of most value; the attempt to determine the conditions causing breaking down of urotropin by kidney or urine; and the relation of acidity by litmus test and hydrogen ion concentration.

EARLE B. FOWLER.

SURGERY OF THE EYE AND EAR

EYE

Ball: Amblyopia from Hæmorrhage. *Interst. M. J.*, 1913, xx, 531. By Surg., Gynec. & Obst.

Of the cases in the literature of disturbance of vision as a result of hæmorrhage, the hæmorrhage was from the stomach in thirty-six per cent, from the uterus in twenty-five per cent, from the nose in seven per cent, from accidental wounds in five per cent, from intentional loss of blood in twenty-five per cent and from pulmonary and urethral bleeding in one per cent.

Disorders of vision following hæmorrhage occur almost without exception in persons who were previously not healthy. In twenty-five per cent of cases loss of sight appeared during or immediately following the hæmorrhage, in twenty per cent during the first twelve hours and in fifty per cent during the first three weeks.

The ophthalmoscope findings do not correspond to the degree of loss of vision. C. G. DARLING.

Meller: Chronic Inflammatory Tumor Formations of the Orbit (Über chronisch-entzündliche Geschwulstbildungen der Orbita). *Arch. f. Ophthalmol.*, 1913, lxxxvii, 146.

By Zentralbl. f. d. ges. Chir. u. i. Grenzgeb.

Meller reports nine cases of chronic inflammatory tumor formations of the orbit which were observed during the last twenty years in Fuchs's clinic. Clinically they appeared as malignant tumors and the operative measures were more or less radical. Histological examinations, however, showed that they were chronic inflammatory tumor formations which in six cases were probably of luetic origin. In two cases the nature was unknown; in one the tumor originated from the frontal cavity.

Meller emphasizes the necessity of ascertaining the malignancy of the tumor by using the tuberculin and Wassermann tests, mercury treatment, examination of the accessory cavities, exploratory excision, etc., before performing any operation.

KIRSCH.

Mathewson: A Case of Pulsating Exophthalmus. *Ophth. Rec.*, 1913, xxii, 294. By Surg., Gynec. & Obst.

Mathewson reports a case of pulsating exophthalmia following a fracture of the base of the skull. When first seen by Mathewson, four weeks after the accident, there was complete ptosis of left upper lid, swelling of conjunctiva, fundus normal vision fingers at eight feet in upper half of field. There was no vision in lower field and no pulsation of eyeball. Vision was undoubtedly damaged by the laceration of the optic nerve. The common carotid was tied

and a month later there was little proptosis and no pulsation or bruit. Vision, of course, was not improved. C. G. DARLING.

Weidler: Concerning Dermoids and Dermolipomas of the Conjunctiva. *Ophth. Rec.*, 1913, xxii, 291. By Surg., Gynec. & Obst.

Weidler reports two cases of dermoid of the cornea, both being located at the outer lower quadrant. Both were solid, one about 5 x 9 mm., the other about 5 x 7 mm. in size. The only other congenital defect was the absence of a nail on the little finger of the right hand in one of the cases. C. G. DARLING.

Wyler: Enucleation Under Ciliary Ganglion Anæsthesia. *Lancet-Clin.*, 1913, cix, 648. By Surg., Gynec. & Obst.

Wyler discusses enucleation under ciliary ganglion anæsthesia and follows the technique of Sowański. In a summary of cases operated on he says:

1. Local anæsthesia is certainly less dangerous and more agreeable than general for enucleation.

2. Upon cutting the optic nerve none of the five cases saw the flash of light to which one sees so many references.

3. The method is a very easy procedure.

4. It is applicable to inflammatory conditions when infiltration has proven unsuccessful.

5. Healing is rapid.

6. He believes that this anæsthesia may be popular in the future for other painful operations upon the globe. C. G. DARLING.

EAR

Nelson: The Value and Indications for Incision of the Eardrum in Otitis Media. *Atlanta J.-Rec. Med.*, 1913, lx, 106. By Surg., Gynec. & Obst.

The author points out the fallacy of considering otitis media as a self-limited disease and of waiting for spontaneous perforation of the eardrum. The word "incise" instead of the term "paracentesis" is suggested and in opening the eardrum for middle ear disease it should be freely incised. The best rule as to the location of the incision is to incise at the point of bulging, if it is localized in some one portion of the eardrum. When the bulging is general, the posterior inferior quadrant of the membrana tympani is the safest and best place to incise. Here an incision can be carried upward and backward to the superior posterior border with the knife plunged deeply enough to incise freely through the mucosa covering the inner wall of the middle ear. For this purpose the von Graefe cataract knife is the simplest and best.

Dr. Nelson reports incision of the drum in 102 cases of acute, and in 3 cases of chronic, otitis media. Only two subsequently required mastoid operations. All of the 102 cases showed objective and subjective symptoms of extension into the mastoid antrum, if not into the mastoid cells, and in practically every case, including the two operated upon, all the symptoms disappeared either wholly or in part within 24 hours.

In those cases of chronic suppurative otitis media in which the drum was incised, only temporary amelioration of the condition was obtained and the procedure had to be repeated several times. These cases were chronic before seen in the clinic.

With the results noted in the acute cases, it is reasonable to suppose that early incision of the drum, or other appropriate treatment, will in all probability arrest serious results. WALTER H. THEOBOLD.

Pierce: Preservation of the Antral Capsule in Operations for Acute Suppurative Processes of the Mastoid. *Tr. Am. Otol. Soc.*, 1913, May.

By Surg., Gynec. & Obst.

The antral capsule may be more or less differentiated from the rest of the bone as it possesses a marked resistance to inflammatory and softening processes to which the mastoid is subject. On this point rests the success of Pierce's operation in preserving the antral capsule. This capsule is that portion of the temporal bone bounded above by diploëtic bone and pneumatic cells lying between the antral cavity and the inner table of the skull, anteriorly by the interposed pneumo-diploëtic bone and compact substance of the external auditory canal; the outer wall by the same character of bone; posteriorly by the compact substance sent in from the roots of the zygomatic process, small pneumatic spaces, and the walls of the sigmoid sinus; and inferiorly by the cubiform plate.

In acute inflammations in the mastoid, perforation of the mastoid antrum is invariably through the cubiform floor and downward, this being the line of least resistance to the softening process. If the box which contains the antrum is destroyed it has been noted that the mucosa from the ear spreads over the osseous structures, making a permanent, large dependent cavity lined with muco-periosteum of very low resistance and hence long after-treatment.

Dr. Pierce's operation procedure is to preserve this box. The incision is made as in all mastoid operations and the antrum entered from below, taking off the cortex of the bone about half an inch from the tip upward to the lower margin of the mastoid fossa, forward to the hard bony substance of the external

auditory canal and posteriorly about a finger's breadth from this. The soft bone is scraped out and a search made for the fistula which is almost invariably found descending from the cubiform plate of the mastoid antrum downward. Only enough of the soft bone from the bottom of the antrum is removed to admit a small rubber drainage tube. The rest of the diseased portion of the mastoid is removed, care being taken to preserve the antrum box. An infant's catheter is then inserted into the antrum, through its floor, and the cavity in the mastoid is packed about the tube with zeroform gauze.

The external auditory canal is also packed with gauze and a 50 per cent alcohol dressing applied over the wound, is changed daily. On the third or fourth day the antrum is irrigated through the catheter, and on the fifth day the packing is removed. If the auditory canal is dry the tube is removed and from then on the wound is packed loosely until sealed.

The advantages of this operation are: (1) Rapidity of healing. (2) Avoidance of ugly, disfiguring scars. (3) The avoidance of a large permanent cavity lined by mucosa from the middle ear.

WALTER H. THEOBOLD.

Comparriol: Two Cases of Trepanation of the Labyrinth, Operation and Cure (Zwei Fälle von Trepanation des Labyrinthes, Operation, Heilung). *El siglo méd.*, 1913, No. 3102, 322.

By Zentralbl. f. d. ges. Chir. u. i. Grenzgeb.

Two cases are reported in which a suppurative otitis media involved the labyrinth (rotatory dizziness). At the operation in both cases the posterior arch was opened. Uninterrupted recovery resulted.

DENKS.

Bellows: Aural Spades and Angular Curettes. *J. Ophth., Otol. & Laryngol.*, 1913, xix, 215.

By Surg., Gynec. & Obst.

Bellows has devised the so-called aural spades for the separation of masses of impacted cerumen from the wall of the canal, at one point, as the first step in its removal. They are non-cutting instruments, and sufficiently thin to be insinuated in the merest chink between the mass and the canal wall, and at the same time are sufficiently strong to permit of considerable pressure on the mass to separate it from the wall. They are to be used only by the experienced and under the control of perfect illumination.

For use in conjunction with Buck's ring curettes, the author has designed a series of angular curettes in blunt form for removing cerumen and exudation, and sharp, for operating. EARLE B. FOWLER.

SURGERY OF THE NOSE, THROAT, AND MOUTH

Ibbotson: Some Notes on the Treatment of Atrophic Rhinitis by Doriform. *Med. Press & Circ.*, 1913, xcvi, 658. By Surg., Gynec. & Obst.

This drug, a greenish yellow organic powder, was used as .5 per cent (corresponding to iodoform 1 per cent) suspension in glycerine or olive oil, and applied with a swab or spray. It was very effective in atrophic rhinitis, in preventing crusting and ozena, and of value in some cases of chronic otitis media. No toxic effects were noted and the author considers it an efficient, odorless substitute for iodoform.

EARLE B. FOWLER.

Gabell: An Extreme Example (Unilateral) of the Antral Cavity Extending Between the Molar Roots. *Proc. Roy. Soc. Med.*, 1913, vi, Odontol. Sect., 128. By Surg., Gynec. & Obst.

This report is the case of a girl aged twenty, whose antrum floor extended 6.5 mm. below the roots of the second molar. Between the roots of the first molar, the floor extended down 4.5 mm., completely occupying the space between the lingual and the disto-buccal roots which act as part of its walls. On the right side the floor did not extend as far as the apices of any of the teeth. There was no history of antrum disease and the wounds healed satisfactorily.

H. A. PORTS.

Tilley: An Instrument for Expediting the Examination of Embedded Tonsils. *Proc. Roy. Soc. Med.*, 1913, vi, Laryngol. Sect., 123.

By Surg., Gynec. & Obst.

The instrument is shaped like an ordinary Frammel's tongue depressor, but the distal end is replaced by a small concave bar placed at right angles to the shaft. If the outer portion of the tonsil is pressed on, the gland tends to face the observer. Often by this instrument may be expressed septic accumulation which otherwise might pass unnoticed.

EARLE B. FOWLER.

Peters: Cyst of Arytæno-Epiglottidean Fold Which Burst Spontaneously. *Proc. Roy. Soc. Med.*, 1913, vi, Laryngol. Sect., 126.

By Surg., Gynec. & Obst.

Symptoms of slight choking and loss of voice grew progressively worse over a period of eight

weeks, during which time the cyst could be seen to enlarge. At the end of that time the symptoms cleared up and the serous fluid could be seen coming from the rent in the capsule. The discussion brought out the necessity of using galvano-cautery or removing the cyst completely to prevent refilling.

EARLE B. FOWLER.

Hopenwell-Smith: The Structure of the Dental Pulp in Ovarian Teratoma. *Proc. Roy. Soc. Med.*, 1913, vi, Odontol. Sect., 131.

By Surg., Gynec. & Obst.

In the discussion of a paper of last year, Bland-Sutton expressed the opinion that it would be of interest to know if the teeth found in ovarian teratomata possess nerves. The study of a specimen which had been fixed en masse in formalin, rapidly decalcified, embedded in a saturated solution of dextrine and cut on an ether freezing microtome, showed small dimension of the pulp, its outline less regular than the normal organ and varying with the shape of the tooth itself. The pulp is composed of a tissue closely resembling that in normal teeth. It has a delicate connective tissue consisting of ramified cells embedded in a slightly fibrous stroma and granular transparent basis substance, plentifully supplied with blood vessels and nerves. The odontogenetic zone is clearly seen, the odontoblasts are short and thick, and the blood vessels run in the direction of the long axis and are accompanied by prominent bundles of medullated nerve fibers which are larger in proportion than those of adult teeth.

H. A. PORTS.

Von Tappeiner: Tuberculosis of the Gums (Über Zahnfleisch-tuberkulose). *Deutsche Ztschr. f. Chir.*, 1913, cxxii, 339.

By Zentralbl. f. d. ges. Chir. u. i. Grenzgeb.

Twenty-six cases of primary tuberculosis of the gums have been reported. Thirty others appeared in cases with pulmonary lesions. The symptoms consist of swelling, sponginess, ulceration and bleeding of the gums. In doubtful cases microscopical examination decides the question. Healing is usually very rapid after radical removal of the diseased tissue. The author describes one case.

Anæsthetics

Anæsthesia and anoci-association. GEO. W. CRILE. Surg., Gynec. & Obst., 1913, xvi, 627.

The kinetic theory of surgical shock and anoci-association. GEO. W. CRILE. Interst. M. J., 1913, xx, 499.

Narcosis: I. Critical survey of the relations between narcosis and respiration of oxygen. HANS WINTERSTEIN. Biochem. Ztschr., 1913, li, 143.

Theoretical considerations on mixed narcosis. Counter-reply to the reply of Bürgis on "Combination of Narcotics." GERTRUD WOKER. Ztschr. f. allg. Physiol., 1913, xv, 49.

Oxygen and anæsthesia. F. H. McMECHAN. Internat. J. Surg., 1913, xxvi, 205.

Nitrous oxide and oxygen anæsthesia. E. M. PRINCE. Surg., Gynec. & Obst., 1913, xvi, 622.

Further report on nitrous oxide-oxygen anæsthesia. SOUTHGATE LEIGH. Am. J. Surg., 1913, xxvii, 222.

The effect of chloroform narcosis upon the protein metabolism; contributions to the physiology of the thyroid gland. ELISABETH HAMBURGER. Arch. f. d. ges. Physiol., 1913, clii, 56.

A new procedure for ether dropnarcosis. NOWIKOFF. Russk. Vrach, St. Petersburg., 1913, xii, No. 19.

A simple method of drop-infiltration narcosis by the aid of gauze compresses. NOWIKOFF. Russk. Vrach, St. Petersburg., 1913, xii, 682.

Anæsthesia by means of infiltration in oto-rhino-laryngology. JACQUES. Rev. méd. de l'est, Nancy, 1913, xlv, No. 11.

Anæsthesia by intratracheal insufflation from the physiological and clinical standpoint. F. COTTON and W. BOOTHBY. Clin. Med., 1913, xii, 159.

Results obtained with intratracheal insufflation after Meltzer's method. STORM VAN LEEUWEN. Nederl. Tijdschr. v. Geneesk., Amst., 1913, i, No. 25.

An artificial airway for surgical anæsthesia. ROBERT H. FERGUSON. J. Am. M. Ass., 1913, lx, 1858.

Textbook of local anæsthesia for students and physicians. GEORG HIRSCHER. Wiesbaden, Bergmann, 1913.

Anæsthesia of the brachial plexus after the method of Kulenkampff. P. BABITZKY. Vrach. Gaz., St. Petersburg., 1913, xx, 681.

Injuries of the nerves in anæsthesia of the solar plexus. M. HIRSCHLER. Zentralbl. f. Chir., 1913, xl, 766.

Intravenous hedonal narcosis. N. I. BERESNEGOWSKI. Chir. Arch. Vellaminova, St. Petersburg., 1913, xxix, 208.

Spinal anæsthesia. BARUCH. J. méd. de Brux., 1913, xviii, No. 22.

The Ingleby lecture on spinal anæsthesia by tropococaine, with a review of 1,295 cases. J. T. J. MORRISON. Brit. M. J., 1913, i, 2738.

Experiences with tropococaine spinal anæsthesia. S. TSURUTA. Sei-I-Kwai M. J., 1913, xxxii, No. 6.

Lumbar anæsthesia by means of novocaine. LÉPOUTRE. J. d. sc. méd. de Lille, 1913, xxxvi, No. 21.

Experiments in regard to the methods of using magnesium narcosis. G. MANSFIELD and STEPHAN BOSANYI. Arch. f. d. ges. Physiol., 1913, cxiii, 75.

The combined scopolamine-pantopon narcosis. J. P. SKIJAROFF. Novole v Med., St. Petersburg., 1913, vii, 129.

The lachrymal gland in surgical anæsthesia. L. T. RUTHERFORD. Brit. M. J., 1913, i, 2738.

Surgical Instruments and Apparatus

Improved device for illuminating the operating room. WILLARD BARTLETT. J. Am. M. Ass., 1913, lx, 1846.

A new lamp for use in diaphanoscopy and endoscopy. HANS REUTER. München. med. Wchnschr., 1913, lx, 1548.

Some simple attachments for electric hand lamps. F. H. VERHOEFF. Ophth. Rec., 1913, xxii, 298.

A radiographic apparatus which can be transported on the automobile. HAZLETON. Arch. d'électr. méd., exp. et clin., Bordeaux, 1913, xxi, No. 360.

Operating table for rhinologists. C. G. DWIGHT. J. Am. M. Ass., 1913, lx, 1951.

Fracture and orthopedic table. G. W. HAWLEY. J. Am. M. Ass., 1913, lx, 1850.

Description of a simple apparatus for the application of plaster jackets in hyperextension. PRESCOTT LE BRETON. Buffalo M. J., 1913, lxviii, 626.

A new sterilizer for instruments, which has a number of compartments and automatically insures sufficient sterilization. GUSTAV SPIESZ. Deutsche med. Wchnschr., 1913, xxxix, 1049.

An apparatus for the sterilization of liquid soap; an apparatus for the sterilization of brushes. ANGELESCO. J. de chir. de Bucarest, 1913, i, No. 1.

A modified La Force adenotome and its use. B. F. BEEBE. Ohio St. M. J., 1913, ix, 280.

A simple canula for puncture, injection and infusion. F. LOTSCH. Zentralbl. f. Chir., 1913, xl, 908.

A new tonsil-snare. L. D. GREEN and A. S. GREEN. J. Am. M. Ass., 1913, lx, 2043.

New tonsil clamps. M. D. STEVENSON. J. Am. M. Ass., 1913, lx, 2044.

A new gastro-intestinal clamp. NUSSBAUM. Zentralbl. f. Chir., 1913, xl, 953.

A new abdominal compress. TSAKONA. Grèce méd., 1913, xv, No. 9.

A universal douche attachment for cystoscopes. A. LEWIN. Ztschr. f. Urol., 1913, vii, 387.

Double vulsellum cervix forceps. H. F. DAY. J. Am. M. Ass., 1913, lx, 1952.

The "Antifluor," a new instrument for the dry treatment of vaginal catarrh. LIEPMANN. München. med. Wchnschr., 1913, lx, 1383.

A new abdominal speculum for use in laparotomies. E. KAUTT. Zentralbl. f. Gynäk., 1913, xxxvii, 902.

SURGERY OF THE HEAD AND NECK

Head

Primary purulent inflammation of the salivary glands in early infancy. JULIUS LEWIN. Arch. f. Kinderh., 1913, lx, 462.

A case of salivary calculus in Wharton's duct; review of subject. E. R. BUSH. Indianapolis M. J., 1913, xvi, 232.

Tumors of the salivary glands. HERMANN HEINEKE. Ergebn. d. Chir. u. Orthop., 1913, vi, 239.

Traumatic facial hemispasm. T. TUFFIER. Bull. et mem. Soc. de chir. de Par., 1913, xxxix, 596. [381]

My experience with the treatment of neuralgia of the trigeminal nerve by injections of alcohol. OFFERHAUS. Nederl. Tijdschr. v. Geneesk., Amst., 1913, i, No. 21.

The cosmetic correction of paralysis of the facial nerve by means of transplantation of fascia. STEIN. München. med. Wchnschr., 1913, lx, No. 25.

Cosmetic improvement of the deformities caused by paralysis of the facial nerve. BUSCH. Ztschr. f. Ohrenh. u. f. d. Krankh. d. Luftwege, 1913, lxviii, Nos. 2-3.

Treatment of neuralgia and facial spasm by nerve injections. H. CAMPBELL. Practitioner, Lond., 1913, xc, 991.

The treatment of facial paralysis by nerve transplantation. STEPHEN H. WATTS. Old Dominion J. M. & S., 1913, xvi, 259.

Some endocranial operations for the treatment of facial neuralgia; pregasserian resections, gasserectomy or retro-gasserian neurotomy. DE BEULE. J. de chir. belge, Brux., 1913, xiii, No. 5.

Partial resection of the inferior maxilla by the buccal path of access in cases of cancer of the isthmus of the pharynx. GAULT. Rev. hebdomadaire de laryngol., d'otol. et de rhinol., Bordeaux, 1913, xxxiv, No. 24.

Unilateral temporo-maxillary ankylosis, diagnosed by the aid of radiography; aponeurotic graft to prevent recurrence. DESCARPENTRIES. Echo méd. du nord, Lille, 1913, xvii, No. 24.

Extended operation for malignant tumors of the upper maxilla. F. KUHN. Deutsche med. Wchnschr., 1913, xxxix, 934.

Protheses of the nose. BRUNO KLEIN. Oesterreich.-ungar. Vierteljahrsschr. f. Zahnheilk., 1913, xxix, 179.

Paraffin prostheses and nasal deformities. LAGARDE. J. de méd. de Par., 1913, xxxiii, 423.

Endothelial sarcoma of the temporal bone. EISENBERG. Vrach. gaz., St. Petersburg, 1913, xx, No. 19.

Sarcoma of the petrous portion of the temporal bone in a child of five years; propagation to the cerebellar meninges and to the roots of the mixed nerves of the base. CRUCHET, DUVERIE and DUBOURG. J. de méd. de Bordeaux, 1913, xliii, No. 24.

Operation for extensive tumors at the base of the skull. SCHLOFFER. Prag. med. Wchnschr., 1913, xxxviii, No. 26.

Cranial deformities associated with ocular symptoms. LARSEN. Hosp.-Tid., Kjøbenhavn, 1913, lvi, No. 25.

Perforating wound of the cranium caused by a revolver bullet; cranio-meningoectomy; recovery. DRE KOLLIAS. Grèce méd., Athens, 1913, xv, No. 7.

The limitations and possibilities of X-ray skull diagnosis. GEO. EARL. J.-Lancet, 1913, xxxiii, 307. [381]

The Röntgen ray as an aid in the diagnosis of fractured skulls. WM. H. STEWART. Am. Quart. Röntgen., 1913, iv, 217.

The diagnostic evidence obtained by X-rays from the lateral aspect of the skull, with especial reference to the base and its adnexa. PERCY BROWN. Boston M. & S. J., 1913, clxviii, 882. [381]

Traumatic epilepsy. MARCHAND. Clinique, Par., 1913, viii, 210. [382]

A contribution to the pathological surgery of Jacksonian epilepsy in uremia. GEIMANOWITSCH and STOMIN. Charakofsky med. J., 1913, xv, 27.

Permeability of the meninges. WEIL and KAFKA. Deutsche Ztschr. f. Nervenhe., Leipz., 1913, xlii, No. 4.

Permeability of the meninges. ZALOZIECKI. Deutsche Ztschr. f. Nervenhe., Leipz., 1913, xlii, No. 4.

Experimental researches on the plexus choriodeus and the meninges. GOLDMANN. Arch. f. klin. Chir., 1913, ci, No. 3.

Primary melanosis of the pia mater. K. J. SCHOPPER. Frankf. Ztschr. f. Path., Wiesb., 1913, xiii, 77.

A case of meningeal tumor. URECHEA and POPEA. Spitalul, Bucuresci, 1913, xxxiii, No. 8.

Serous meningitis. L. E. GREGMAN and G. KRUKOWSKI. Monatschr. f. Psychiat. u. Neurol., 1913, xxxiii, 283.

Some remarks on meningitis, with a report of two fatal cases in which Haunes' operation was performed. H. WILSON. *Physician & Surg.*, 1913, xxxv, 241.

Prognosis and treatment of meningitis. REICHMANN. *München. med. Wchnschr.*, 1913, lx, No. 25.

Investigations in regard to the relations of certain tissue reactions to the early diagnosis and surgical treatment of meningitis. KOPETZKY. *Ztschr. f. Ohrenh. u. f. d. Krankh. d. Luftw.*, 1913, lxviii, 1.

The autoplasmic closure of dural defects. SMIRNOFF. *Dissertation, St. Petersburg.*, 1913. [382]

The technique of arresting hæmorrhage from the sinus of the brain. M. BORCHARDT. *Zentralbl. f. Chir.*, 1913, xl, 1003.

A case of idiopathic hydrocephaly in an adult. VIRCHOWSKY. *Pract. Vrach, St. Petersburg.*, 1913, xii, No. 19.

The operative treatment of hydrocephalus. R. WENGLOWSKI. *Chir. Arch. Vellaminova*, 1913, xxix, 179. [382]

Puncture of the corpus callosum. E. ARCHIBALD. *Canad. M. Ass. J.*, 1913, iii, 451. [383]

Phenomena of cranial hypertension and lumbar puncture. BABINSKI. *J. d. praticiens, Par.*, 1913, xxvii, No. 26.

The cure of a traumatic ventricular fistula. GOEPEL. *Zentralbl. f. Chir.*, 1913, xl, 869.

The anatomical results of air embolism of the brain. SPIELMEYER. *Kong. f. inn. Med., Wiesbaden*, 1913.

Diagnosis and surgical treatment of some brain diseases. Z. BYCHOWSKI. *Neurol. Zentralbl.*, 1913, xxxii, 613.

Cerebral concussion with localizing symptoms; a report of three cases; recovery following surgical treatment. T. KLINGMANN. *Physician & Surg.*, 1913, xxxv, 249.

Destructive contusion of the right cerebral hemisphere by a bullet, without lesion of the cranial wall or the dura mater. GIORGI. *Rev. osp., Roma*, 1913, iii, No. 10.

Injuries of the brain, spinal cord and nerves in the German Red Cross hospital in Belgrade. MUHSAM. *Arch. f. klin. Chir.*, 1913, ci, No. 3.

Abscess of the parietal lobe; hemianæsthesia; dyssymmetry and bradycinesia; asynergy; apraxia; disturbance of inhibitory functions. ANDRÉ-THOMAS. *Rev. neurol., Par.*, 1913, xxi, No. 10.

A case of cerebral abscess during bronchiectasis. SPAL. *Čas. lék. česk., Prague*, 1913, lii, No. 20.

Some general symptoms and their significance in the early diagnosis and treatment of cerebral tumors. LANDAU. *Przegl. lek., Krakow*, 1913, lii, No. 24.

The so-called binasal hemianopsia in brain tumors. W. B. LANCASTER. *Boston M. & S. J.*, 1913, clxviii, 878.

The absence of brain tumor symptoms in cases of tumors of the brain. W. J. BEERMAN. *Calif. St. J. Med.*, 1913, xi, 234.

A case of cerebral tumor. G. A. WETTERSTRAND. *Finsk. läk.-sällsk. handl., Helsingfors*, 1913, lv, 338.

A case of cavernous angioma of the brain. W. J. SWEASEY POWERS. *Ztschr. f. d. ges. Neurol. u. Psychiat.*, 1913, xvi, 487.

Researches on diffuse sarcomata in the central nervous system. A. WIMMER and HANS HALF. *Ztschr. f. d. ges. Neurol. u. Psychiat.*, 1913, xvi, 497.

Subdural hæmatoma. BERTELSMANN. *Med. Klin.*, 1913, ix, No. 23.

Endothelioma psammoma on the base of third ventricle of the brain and interpeduncular arachnoideal cyst, a tumor found principally in the cerebellum; the operation. H. HIGIER. *Neurol. Zentralbl.*, 1913, xxxii, 741.

Some cases of brain surgery in a country doctor's practice. E. E. LIGGETT. *J. Kansas M. Soc.*, 1913, xiii, 225.

Localization in the cortex of the cerebellum in man. BÁRÁNY. *Hygiea, Stockholm*, 1913, lxxv, No. 5.

Tumor of the cerebellum. SAMUEL S. ADAMS. *Arch. Pediatrics*, 1913, xxx, 465.

A case of a tumor of the cerebellum developing after a slight traumatism. THEILAND. *Ugesk. f. Læger, Kjøbenhavn*, 1913, lxxv, No. 25.

Another case of tuberculoma of the cerebellum. SALVATORE MAGGIORE. *Pediatrics*, 1913, xxi, 332.

Contributions to the histology of the human pineal gland. F. K. WALTER. *Ztschr. f. d. ges. Neurol. u. Psychiat.*, 1913, xvii, 65.

Affections of the pineal gland. ARTUR SCHÜLLER. *Handb. d. Neurol.*, 1913, iv.

A tumor of the pineal gland or of the cerebral epiphysis. VON HASSELT. *Nederl. Tijdschr. v. Geneesk., Amst.*, 1913, i, No. 19.

Case of infantilism associated with hypophysis tumor. E. J. MULLALLY. *Arch. Internal Med.*, 1913, xi, No. 5.

A new path of access for interventions on the hypophysis. NOWIKOFF. *Zentralbl. f. Chir.*, 1913, xl, No. 25.

A new operative method for the experimental study of the hypophysis. SCINICARIELLO. *Riforma med.*, 1913, xxix, No. 24.

Operations on the hypophysis by the nasal path; account of a personal case. HOLMGREN. *Hygiea, Stockholm*, 1913, lxxv, No. 5.

Neck

Is it always possible to avoid the facial twigs of the cervico-facial branch of the 7th pair in operations on the submaxillary fossa? A. POGGIOLINI. *Clin. chir.*, 1913, xxi, 1090. [383]

Abscess beneath the deep cervical fascia. N. A. POWELL. *Canad. Pract. & Rev.*, 1913, xi, 332.

A case of actinomycosis of the neck treated by subcutaneous injections of iodopin. FRANZ BITTNER and JOSEF TOMAN. *Prag. med. Wchnschr.*, 1913, xxxviii, 383.

A plasma-cell granuloma with the clinical picture of lymphoma of the lymphatic glands of the neck and inflamed nodules in the mucous membrane of the nose. KUSONOKI, MASANOBU and FRANK. *Virchow's Arch. f. path. Anat. u. Physiol.*, 1913, ccxii, 391.

Neurogenous wry neck. ALBERT BAUER. *Ergebn. d. Chir. u. Orthop.*, 1913, vi, 335.

Cervical ribs. K. MENDEL. *Neurol. Zentralbl.*, 1913, xxxii, 556.

The thyroid and parathyroid problem. JASPER HALPENNY. *Surg., Gynec. & Obst.*, 1913, xvi, 595. [384]

The spherulites of the thyroid gland. KRAUS. *Virchow's Arch. f. path. Anat. u. Physiol. u. f. klin. Med.*, 1913, ccxii, No. 3.

Echinococcus cysts of the thyroid gland. A. LANDIVAR. *Rev. de la méd. argent.*, 1913, xxi, 213.

Osteosarcoma of the thyroid gland. SOLARO. *Clin. chir., Milano*, 1913, xxi, No. 5.

The pathological anatomical changes in the thyroid of children in scarlet fever. K. E. GREGOR. *Pædiatria, St. Petersburg.*, 1913, iv, 285.

The relationship of thyreoparathyroidectomy to the carbohydrate metabolism. S. MIURA. *Biochem. Ztschr.*, 1913, li, 423.

Morphological studies in experimental cretinism. TATUM. *J. Exp. Med.*, 1913, xvii, 636. [384]

Acute Basedow's disease. FUNKE. *Prag. med. Wchnschr.*, 1913, xxxviii, No. 23.

The frequent occurrence of mild cases of Basedow's disease and the favorable influence exerted upon them by hygienic-climacteric factors. KUHN. *Med. Klin.*, 1913, ix, 834. [384]

An attempt to influence Basedow's disease by X-rays

applied to the ovaries. MANNABERG. *Wien. klin. Wchnschr.*, 1913, xxvi, 693. [384]

The operative treatment of Basedow's disease. SCHLOFFER. *Prag. med. Wchnschr.*, 1913, xxxviii, 313. [384]

Exophthalmic goiter; hyperthyroidism. W. B. WEIDLER. *N. Y. M. J.*, 1913, cxvii, 1293.

Hyperthyroidism and its treatment. STUART MCGUIRE. *Va. M. Semi-Month.*, 1913, xviii, 105.

SURGERY OF THE CHEST

Chest Wall and Breast

The internal secretion of the mamma. ALBRECHT. *Deutsche Gesellsch. f. Gynäk.*, Halle, 1913, May. [385]

Pathological and clinical contributions on cancer of the breast. ALBERT SALOMON. *Arch. f. klin. Chir.*, 1913, ci, 573.

Cancer of the breast and hæmatic secretion; a case of "bleeding breast." POZZO. *Morgagni*, 1913, lv, No. 5.

Successful removal of an ulcerated carcinoma of the breast by the "Halstead method." JOSEPH D. FARRAR. *Penn. M. J.*, 1913, xvi, 705.

The problem in local recurrent breast cancer. C. W. STEOBELL. *N. Y. M. J.*, 1913, xcvi, 1176.

Paget's disease. A. A. SSINOSERSKI. *Chir. Arch. Velfaminova*, 1913, xxix, 336. [385]

Tuberculosis of the breast. A. D. KAPLAN. *Chirurgia*, 1913, xxxiii, 322.

Boning of the thoracic precordial wall in certain affections of the heart; report of case. J. E. SUMMERS. *Am. J. Surg.*, 1913, xxvii, 230.

Intrascapular thoracic amputation. EPSTEIN. *Chirurgia*, 1913, xxxiii, 344. [385]

Interscapulothoracic amputation of the shoulder. NORMAN B. CARSON. *Ann. Surg.*, Phila., 1913, lvii, 796. [385]

Multiple fractures of the thorax and the shoulder blade; a fracture and luxation of the shoulder. MATTEI, MARTIN-LEVAL and REBOUL-LACHAUX. *Marseille méd.*, 1913, l, No. 12.

Double luxation of the clavicle. KAMPTZ. *Med. Klin.*, 1913, ix, No. 25.

Fractures of the clavicle. DELBET. *J. d. praticiens*, Par., 1913, xxvii, No. 22.

Congenital cysts of the sternal region. H. L. ROCHER. *Enfance*, 1913, i, 346.

A report of seventeen cases of pulmonary tuberculosis treated by artificial pneumothorax. H. L. BARNES and F. T. FULTON. *Boston M. & S. J.*, 1913, clxviii, 917.

Indications and technique for artificial pneumothorax in pulmonary tuberculosis. A. STERNBERG. *Verhandl. d. wiss. Ver. d. Ärzte d. städt. Obuchow-Krkh.*, St. Petersburg, 1913, xxii, 27. [386]

Artificial pneumothorax for pulmonary hæmorrhage. A. STERNBERG. *Verhandl. d. wiss. Ver. d. Ärzte d. städt. Obuchow-Krkh.*, St. Petersburg, 1913, xxii, 34. [386]

Experimental studies in the treatment of pneumothorax. What effect does unilateral pneumothorax have on the tuberculous phenomena which follow intravenous and intratracheal infection? H. SCHUR and SIEGFRIED PLASCHKE. *Ztschr. f. exp. Path. u. Therap.*, 1913, xiii, 478.

The treatment of closed pneumothorax by means of aspiration and hyperpressure. GREIFFENHAGEN. *Zentralbl. f. Chir.*, 1913, xl, No. 23.

Empyema in infancy. FRITZ ZYBELL. *Ergebn. d. inn. Med. u. Kinderh.*, 1913, xi, 611.

A case of chronic empyema cured by resection of the ribs and decortication of the lung according to Delorme. DERJUSHINSKI. *Chirurgia*, 1913, xxxiii, 497.

Recurrent purulent pleurisy. COMBY. *Arch. de méd. d. enfants*, Par., 1913, xvi, No. 6.

Chronic mediastinitis following osteomyelitis of the sternum; report of a case and operation. H. M. ARMISTAGE. *N. Y. M. J.*, 1913, xcvi, 1244.

Two cases of primary tumors of the mediastinum. THÉVENOT and ROUBIER. *Gaz. d. hôp.*, Par., 1913, lxxxvi, No. 68.

X-ray diagnosis of tuberculosis of the bronchial glands in children. NEUHAUS. *Fortschr. a. d. Geb. d. Röntgenstr.*, 1913, xx, No. 4.

Trachea and Lungs

Tracheobronchoscopy after the method of Killian. NIKOLSKY. *Russk. Vrach*, 1913, xii, 720.

Two cases of death in bronchoscopic extraction of foreign bodies. HINSBERG. *Ztschr. f. Ohrenh. u. f. d. Krankh. d. Luftw.*, 1913, lxviii, No. 2.

Experiences in surgery of the upper respiratory and alimentary tracts. GLUCK. *Berl. klin. Wchnschr.*, 1913, l, 953.

Primary cancer of the lung. WICZKOWSKI. *Wien. klin. Wchnschr.*, 1913, xxvi, No. 26.

A case of suture of a bullet wound of the pulmonary artery. GEORG MARTIN. *Med. Cor.-Bl. d. württemb. ärztl. Landesver.*, 1913, lxxxiii, 333.

Total pulmonary embolism as a cause of post-operative death. PETREN. *Beitr. z. klin. Chir.*, 1913, lxxxiv, No. 3.

Operative treatment of pulmonary embolisms. SCHUMACHER. *Arch. f. klin. Chir.*, 1913, ci, No. 3.

Modifications of the functioning of the diaphragm during pulmonary emphysema. HIRTZ and BRAUN. *Progrès méd.*, Par., 1913, xlv, No. 25.

Heart and Vascular System

Direct massage of the heart. WREDE. *Arch. f. klin. Chir.*, 1913, ci, No. 3.

Massage of the heart in chloroform syncope. GINO PIERI. *Riv. osp.*, Roma, 1913, iii, 304.

Traumatic rupture of the heart. PAPITOFF. *Pract. Vrach*, St. Petersburg, 1913, xii, Nos. 21 and 22.

Conservative cardiac surgery. MAX VON ARX. *Cor.-Bl. f. schweiz. Ärzte*, 1913, lxiii, 717.

Treatment of pericarditis with posterior extravasation. GORSE. *Progrès méd.*, Par., 1913, xlv, No. 23.

Extravasations of the pericardium. RAILLET. *Arch. méd.-chir. de Province*, Poitiers, 1913, viii, No. 5.

Posterior drainage of the pericardium and the pleura. TIEGEL. *Zentralbl. f. Chir.*, 1913, xl, No. 23.

The surgical treatment of pericarditis. KOLB. *Berl. klin. Wchnschr.*, 1913, l, No. 23.

A case of sacciform aneurism of the thoracic aorta. ROMANELLI. *Policlin.*, Roma, 1913, xx, No. 23.

The X-ray diagnosis of thoracic aneurism. R. D. CARMAN. *J. Mo. St. M. Ass.*, 1913, ix, 389.

Pharynx and Oesophagus

Examination of the hypopharynx and of the orifice of the oesophagus. BOUTIN. *Ann. d. mal. de l'oreille, du larynx, du nez et du pharynx*, Par., 1913, xxxix, No. 5.

Cast of epithelial lining of the œsophagus from a case of chloroform poisoning. G. N. BIGGS. *Proc. Roy. Soc. Med.*, 1913, vi, Laryngol. Sect., 123. [386]

Occlusion of the œsophagus by an intestinal nodule. DELANGALDE, WEILL and GAUTHIER. *Marseille méd.*, 1913, l, No. 11.

Foreign bodies in the œsophagus; two cases of rare complications. GANTZ. *Med. i kron. lek.*, 1913, xlviii, Nos. 24 and 25.

The removal of a foreign body from the œsophagus without making a lateral incision in the neck (tracheotomy lateralis). FELIX FRANKE. *Deutsche med. Wchnschr.*, 1913, xxxix, 1143.

Idiopathic dilatation of the œsophagus and Zenker's pharyngeo-œsophageal pressure diverticulum. JOHNSON. *Finsk. l k.-s llsk. handl.*, Helsingfors, 1913, lv, No. 5.

Diagnosis and treatment of cicatricial stenoses of the

œsophagus. GUISEZ. *Arch. d lectr. m d., exp. et clin.*, Bordeaux, 1913, xxi, No. 360.

A carcinoma of the œsophagus on dysontogenetic basis. GRABOWSKI. *Beitr. z. path. Anat. u. z. allg. Path.*, Jena, 1913, lvi, No. 2.

Experimental contributions on surgery of the œsophagus. HOHMEIER and MAGNUS. *Med. Klin.*, 1913, ix, No. 22.

Thoracic œsophagectomy; report of a case. J. Y. BARBAT. *Calif. St. J. Med.*, 1913, xi, 225.

Pharyngectomy for epithelioma; recovery lasting three years. ABOULKER. *Bull. m d. de l'Alg rie*, Alger, 1913, xxiv, No. 10.

The first successful case of resection of the thoracic portion of the œsophagus for carcinoma. TOREK. *Surg., Gynec. & Obst.*, 1913, xvi, 614. [386]

The surgical treatment of carcinoma of the œsophagus. MEYER. *M nchen. med. Wchnschr.*, 1913, lx, No. 24.

SURGERY OF THE ABDOMEN

Abdominal Wall and Peritoneum

Longitudinal or transverse incision? HELLENDAL. *Zentralbl. f. Gyn k.*, 1913, xxxvii, No. 25.

Pfannensti l's incision; technique; advantages and operative indications. SENECHAL and ENGEL. *Gaz. d. h p.*, Par., 1913, lxxxvi, No. 64.

A case of ossification in a laparotomy cicatrix. MARIO BORCHI. *Morgagni*, 1913, lv, 226.

The question of abdominal drainage. J. Y. WEINSTEIN. *J. Indiana St. M. Ass.*, 1913, vi, 258.

Fibroma of the abdominal wall. DUCUING and MARTY. *Toulouse m d.*, 1913, xv, No. 10.

A pedunculated necrotic tumor the size of a fist in the region of the umbilicus. K STNER. *Deutsche Gesellsch. f. Gyn k.*, Halle, 1913, May. [387]

Retroperitoneal abdomino-scrotal cystic lymphangioma. GAUDIER and GORSE. *Presse m d.*, Par., 1913, xxi, No. 46.

Intimate relations of the peritoneum to the uterine musculature. LA TORRE. *Arch. mens. d'obst. et de gynec.*, Par., 1913, ii, No. 5.

Peritoneal adhesions of the insidious toxic group. R. T. MORRIS. *Med. Herald*, xxxii, 199.

Biliary peritonitis without perforation of the bile passages. MACHEFER. *Th se de doct.*, Par., 1913. [387]

Remarks on the contribution of Prof. Nauwerck and Dr. L bke on "Does a Biliary Peritonitis Exist without Perforation of the Bile Passages." CLAIRMONT and VON HABERER. *Wien. klin. Wchnschr.*, 1913, xxvi, 891. [388]

Pneumococcic peritonitis. BARADULIN. *Chirurgia*, 1913, xxxiii, 527. [388]

Tubercular peritonitis. GERHARDT. *M nchen. med. Wchnschr.*, 1913, lx, 1629.

Two cases of tuberculous peritonitis treated by heliotherapy. A. CANTILENA. *Pediatrics*, 1913, xxi, 340.

Camphorated oil in peritonitis and abscesses of the cul-de-sac of Douglas. BLECHER. *M nchen. med. Wchnschr.*, 1913, lx, No. 23.

Development and aims of modern surgery in peritonitis. GLUCK. *Arch. f. Kinderh.*, 1913, lx-lxi, May.

The origin of tumors of the peritoneum (epiploitis plastica). EUGEN HOLL NDER. *Deutsche med. Wchnschr.*, 1913, xxxix, 845.

Pseudo-myxoma of the peritoneum of appendicular origin. DELETREZ. *J. de chir. belge*, Brux., 1913, xiii, No. 5.

Angioplastic surgery of the peritoneum by the employment of pedunculated flaps. JIANO. *J. de chir. de Bucarest*, 1913, i, No. 1.

The etiology of hernias. PAUL BERNSTEIN. *Med. Reform*, Berl., 1913, xxi, 236.

R ntgenological demonstration of diaphragmatic eventration. K. KAYSER. *Fortschr. a. d. Geb. d. R ntgenstr.*, 1913, xx, 240.

Hernia in infancy and childhood. DAVID ROSS. *J. Indiana St. M. Ass.*, 1913, vi, 270.

Cooper's hernia. A. P. KRYMOW. *Arch. f. klin. Chir.*, 1913, ci, 565.

A case of strangulated crural hernia associated with herniary appendicitis. LAHOZ. *Rev. med. d. Rosario*, Rosario de Santa-F , 1913, iii, No. 2.

Permanent results of operations for strangulated crural hernia. ROSENFELD. *Beitr. z. klin. Chir.*, 1913, lxxxiv, No. 3.

Incarcerated hernia associated with ascaris lumbricoides. M. NIWA. *Igaku-Chuwo-Zassi*, 1913, No. 150.

Retrograde incarceration, hernia "en W." WALTHER WENDEL. *Ergebn. d. Chir. u. Orthop.*, 1913, vi, 536. [388]

A case of spontaneously incarcerated diaphragmatic hernia of the stomach, the spleen and a loop of bowel. SWETSCHNIKOW. *Morskoi Vrach*, 1913, April, 217. [389]

A case of diaphragmatic hernia in a phthisic adult. MELCHIOR. *Ugesk. f. L ger*, K benhavn, 1913, lxxv, No. 26.

A new method of treating umbilical hernia. J. H. PRINGLE. *Edinb. M. J.*, 1913, x, 493.

Inguinal hernia—a result of an accident? BIER. *Ztschr. f. Versicherungsmed.*, 1913, vi, 148.

The choice of operation for inguinal hernia. E. G. STERNER. *St. Paul M. J.*, 1913, xv, 290.

New operation for the cure of indirect inguinal hernia. U. C. BATES. *J. Am. M. Ass.*, 1913, lx, 2032.

The radical operation for intestinal hernia with incomplete hernial sac. SCHMIDT. *Deutsche Ztschr. f. Chir.*, 1913, cxxii, 266. [390]

Radical operation for hernia under cocaine analgesia; experience in twenty-five cases. R. G. SAYLE. *Wis. M. J.*, 1913, xii, 13.

Autoplastic suture material for use in herniotomy operations. GOLANITZKE. *Zentralbl. f. Chir.*, 1913, xl, 905.

The functions of the omentum and practical consequences which develop from their study. GUTIERREZ. *Rev. ibero-am r. de ci nc. med.*, Madrid, 1913, xxix, No. 105.

The importance of the omentum from the physiological and pathological point of view. GUNDERMANN. *Beitr. z. klin. Chir.*, 1913, lxxxiv, 587.

Sarcoma of the omentum. M. A. TATE. *Am. J. Obst.*, N. Y. 1913, lxxvii, 1142. [390]

Cystic lymphangioma of the mesentery. D. RÓNA. *Beitr. z. klin. Chir.*, 1913, lxxxiv, 122.

Chylous cyst of mesentery. A. L. BENEDICT. *Surg., Gynec. & Obst.*, 1913, xvi, 606. [390]

Thrombosis of the mesenteric artery. ERNEST LAPLACE. *Penn. M. J.*, 1913, xvi, 699.

The surgical aspects of persistent Meckel's diverticulum. HAMILTON DRUMMOND. *Surg., Gynec. & Obst.*, 1913, xvi, 656. [390]

Gastro-Intestinal Tract

The position and form of the normal human stomach. PATTERSON. *Brit. M. J.*, 1913, i, 1205.

A note on the shape of the normal empty stomach. J. S. B. STOPPORD. *Brit. M. J.*, 1913, i, 1206.

Movements of the stomach, the pylorus and the duodenal bulb. CARNOT. *Paris méd.*, 1913, No. 29.

Functional diagnosis of stomach diseases after Sahli's method. ZNOJEMSKY. *Deutsche Ztschr. f. Chir.*, 1913, cxxii, Nos. 5-6.

Röntgenoscopic examinations versus clinical methods in the diagnosis of gastric disease. J. D. DUNHAM. *Med. Rec.*, 1913, lxxxiii, 1066.

The röntgenological behavior of the stomach in gastric crises and in vomiting. CZYHLARZ and SELKA. *Wien. klin. Wchnschr.*, 1913, xxvi, No. 22.

Acute dilatation of the stomach and its treatment. O. BORCHGREVINK. *Surg., Gynec. & Obst.*, 1913, xvi, 662. [391]

Gastric dilatation; its treatment by removal of gastric contents, starvation and rest in bed. ANDERS FRICK. *J. Am. M. Ass.*, 1913, lx, 1859.

Histological examination of the mucous membrane of the stomach in ulcer and cancer of the stomach. HEYROVSKY. *Deutsche Ztschr. f. Chir.*, 1913, cxxii, 359. [391]

The etiological relationship between ulcer and cancer of the stomach. G. D. HEAD. *J.-Lancet*, 1913, xxxiii, 301.

The relations between carcinoma and peptic ulcer of the upper digestive tract. GRÜBER. *Ztschr. f. Krebsforsch.*, 1913, xiii. [391]

Ulcer of the stomach. SAM C. SLOCUM. *Med. Sentinel*, 1913, xxi, 967.

Round ulcer of the stomach. CRÄMER. *Ztschr. f. ärztl. Fortbild.*, 1913, x, 333.

The perforated gastric ulcer. SEIDEL. *Zentralbl. f. Chir.*, 1913, xl, 910. [391]

Perforating ulcers of the stomach and duodenum. J. MORLEY. *Practitioner*, Lond., 1913, xc, 997.

A report of six cases of acute perforating ulcer of the stomach. G. M. CUSHING. *J. Am. Inst. Homœop.*, 1913, v, 1253.

An extremely rare case of perigastric hæmatoma as a secondary symptom of perforation of gastric ulcers. MEINERT. *Arch. f. Verdauungskrankh.*, Berl., 1913, xix, No. 3.

Results obtained with the internal treatment of ulcer of the stomach, or of the duodenum, associated with congestive insufficiency. K. PETRÉN, K. LEWENHAGEN and J. THORLING. *Mitt. a. d. Grenzgeb. d. Med. u. Chir.*, 1913, xxvi, 256.

The administration of ox bile in the treatment of hyperacidity and of gastric and duodenal ulcer. F. W. PALFREY. *Am. J. M. Sc.*, 1913, cxlv, 796. [391]

Methods of diagnosis in gastric cancer. J. M. FORTESCUE-BRICKDALE. *Bristol Med.-Chir. J.*, 1913, xxxi, 108.

Gastric achylia and its value for the diagnosis of cancer. SCHORLEMMER. *Arch. f. Verdauungskrankh.*, Berl., 1913, xix, No. 3.

A contribution to the surgery of gastric carcinoma; a report of 612 cases observed by Prof. Wolfier between 1895 and 1911. ALTSCHUL. *Beitr. z. klin. Chir.*, 1913, lxxxiv, 421.

Palliative operations for the relief of incurable carcinoma of the stomach. W. J. MAYO. *St. Paul M. J.*, 1913, xv, 269. [392]

Myomata of the stomach, with report of a case terminating fatally by hæmorrhage. C. B. FARR and ROBT. A. GLENN. *N. Y. M. J.*, 1913, xcvi, 26.

Painful occlusion in a bilocular stomach. CLÉMENT. *Marseille méd.*, 1913, iv, 248. [392]

A case of bilocular stomach, diagnosed by means of radiology and operated by the method of gastro-anastomosis. VIGNARD. *Arch. prov. de chir.*, Par., 1913, xxii, No. 4.

Constipation, headaches, and other constitutional states in relation to displacements of the stomach and colon. CHAS. A. L. REED. *Ohio St. M. J.*, 1913, ix, 265.

Gastrocolic fistula, with clinical and röntgenological findings. RUDOLF NEUMANN. *Fortschr. a. d. Geb. d. Röntgenstr.*, 1913, xx, 398.

Operative stenosis of gastric fistulæ by means of transplantation of fasciæ. HACKER. *Zentralbl. f. Chir.*, 1913, xl, No. 22.

Technique of the suture in gastrostomy after Witzel. KRJUKOW. *Arch. f. klin. Chir.*, 1913, ci, No. 3.

Anterior gastro-enterostomy. D. C. BALFOUR. *Ann. Surg.*, Phila., 1913, lvii, 902. [392]

Resection of the stomach. ALFRED PERS. *Deutsche med. Wchnschr.*, 1913, xxxix, 1143.

The technique of resection of the stomach and large intestine. GELINSKY. *Zentralbl. f. Chir.*, 1913, xl, 713.

Simultaneous resection of the stomach and transverse colon. M. GOULLIQUO. *Lyon chir.*, 1913, ix, 473. [393]

Exclusion of the pylorus by constrictive measures. BAGGIO. *Clin. chir.*, 1913, xxi, No. 5.

Exclusion of the pylorus by means of a detached band of aponeurotic fascia or tendon. NASSELLI. *Clin. chir.*, Milano, 1913, xxi, No. 5.

Lacing and closing of the pylorus with omentum. MOMBURG. *Deutsche med. Wchnschr.*, 1913, xxix, 1096. [393]

The vena præpylorica. SARMIENTO. *Rev. Soc. méd. argent*, 1913, xxi, 208.

Duodenal ulcer. HAENEL. *Zentralbl. f. Chir.*, 1913, xl, 912. [393]

A case of duodenal ulcer. YAGUE. *Rev. ibero-amer. de cienc. med.*, Madrid, 1913, xxix, No. 105.

The positive diagnosis of duodenal ulcer by means of the Röntgen ray. GEORGE W. ARIAL and ISAAC GERBER. *Am. Quart. Röntgen.*, 1913, iv, 187.

Duodenal ulcer of the hæmorrhagic form. CASTAIGNE. *Paris méd.*, 1913, viii, No. 24.

Ulcer of the duodenum and cholelithiasis. OETTINGER. *Paris méd.*, 1913, No. 27.

New instruments for the duodenum and small intestine. MAX EINHORN. *Med. Rec.*, 1913, lxxxiii, 1119.

Duodeno-jejunal hernia in nurslings. E. VOGT. *Monatschr. f. Geburtsh. u. Gynäk.*, 1913, xxxvii, 817.

Radical operation for post-operative peptic ulcer of the jejunum. HABERER. *Arch. f. klin. Chir.*, 1913, ci, No. 3.

Simple ulcers of the jejuno-ileum. CADE, ROUBIER and MARTIN. *Progrès méd.*, Par., 1913, xlv, No. 24.

Gall-stones producing pyloric and jejunal obstruction. W. WAYNE BABCOCK. *N. Y. M. J.*, 1913, xcvi, 1169.

Accidents and technique of jejunostomy. BÉRARD and ALAMARTINE. *Rev. de chir.*, 1913, xlvii, 660. [393]

A new method of registering intestinal action. TRENDLENBURG. *Ztschr. f. Biol.*, 1913, lxi, 67.

Intestinal invagination. VACCARI. *Policlin.*, Roma., 1913, xx, No. 6.

The etiology of intestinal invagination. TREPLIN. *München. med. Wchnschr.*, 1913, lx, 1204.

Two cases of intestinal invagination attributable to rare causes. HOHMEIER. *Med. Klin.*, 1913, ix, No. 23.

Intestinal invagination in a child and its medico-surgical treatment. SAVARIAUD. *Clinique*, Par., 1913, viii, No. 25.

Intestinal occlusion by volvulus in a herniary sac. MARANGONI. *Gazz. d. osp. e d. clin.*, Milano, 1913, xxxiv, No. 70.

X-ray diagnosis of stenosis and ileus of the small intestine. STIERLIN. *Med. Klin.*, 1913, ix, No. 25.

Post-operative ileus. SCHUBERT. *Ztschr. f. Geburtsh. u. Gynäk.*, 1913, lxxviii, No. 2.

Gall-stone ileus; with a report of two cases and two methods of opening the intestine. J. S. BROWN. *Surg., Gynec. & Obst.*, 1913, xvi, 709.

Acute intestinal occlusion by a gall-stone; operation; recovery. DELAGENIÈRE. *Arch. méd. d'Angers*, 1913, xvii, No. 6.

A case of intestinal obstruction by gall-stone. G. SCHWYZER. *J.-Lancet*, 1913, xxxiii, 311.

Compression of the small intestine by the spleen and its complications. GHEORGHIN. *Gaz. med.*, Bucuresci, 1913, ii, No. 20.

False intestinal diverticulum and its clinical significance. P. REICHEL. *Zentralbl. f. Chir.*, 1913, xl, 913.

Operative technique in intussusception. S. C. BEEDE. *Am. J. Surg.*, 1913, xxvii, 208.

Classification, etiology, pathology, symptoms, diagnosis and treatment of intestinal tuberculosis. S. G. GANT. *Post-Graduate*, 1913, xxviii, 517.

Tuberculous stenosis of the small intestine. GRÉGOIRE. *Paris méd.*, 1913, No. 27.

Intestinal and pulmonary tuberculosis in a patient who had been gastrectomized for cancer. ROUBIER and GOYET. *Lyon méd.*, 1913, cxx, No. 22.

Volvulus of the cæcum, ascending colon and initial portion of the transverse colon; death from intestinal hæmorrhage. VIGUIER. *Bull. et mem. Soc. de chir. de Par.*, 1913, xxxix, 932.

Incompetency of the ileocæcal valve; disorders arising from this condition and their treatment. JOHN H. KELLOGG. *Med. Rec.*, 1913, lxxxiii, 1105. [394]

Carcinoma of the cæcum. JENCKEL. *München. med. Wchnschr.*, 1913, lx, 1515.

Tuberculous hypertrophy of the cæcum. MONZARDO. *Riforma med.*, 1913, xxix, No. 22.

Primary typhlitis. FRANZ OBÁL. *Beitr. z. klin. Chir.*, 1913, lxxxiv, 201. [395]

Pathology and therapy of perityphlitis (appendicitis). SONNENBURG. *Leipzig: Vogel*, 1913. [395]

Membranous pericolicitis (Jackson's membrane) and Lane's kink. CHAS. RYAN. *Proctologist*, 1913, vii, 75.

Resection of the ileocæcum because of invagination by a submucous lipoma. KARL ANDRÉE. *Beitr. z. klin. Chir.*, 1913, lxxx, 115.

The "Y" cæco-sigmoidostomy. LARDENNOIS and OKINCZYC. *J. de chir.*, 1913, x, 538. [395]

Hyper-acid gastropathy of appendicular origin. SANTE SOLIERI. *Rev. osp.*, Roma, 1913, iii, No. 10.

The origin of inflammations in the appendix on the basis of bacteriological and experimental evidence. HEILE. *Mitt. a. d. Grenzgeb. d. Med. u. Chir.*, 1913, xxvi, 345. [397]

The value currently attributed to examination of the blood in appendicitis and in progressive appendicular peritonitis. WALTER SCHULTZE. *Mitt. a. d. Grenzgeb. d. Med. u. Chir.*, 1913, xxvi, 61.

Chronic appendicitis. ADRON. *Arch. f. Verdauungs-krankh.*, Berl., 1913, xix, No. 3.

Scoliosis and chronic appendicitis. MAYET. *J. d. praticiens*, Par., 1913, xxvii, No. 24.

The diagnosis and treatment of acute appendicitis. EDWIN WALKER. *Lancet-Clin.*, 1913, cix, 629.

Treatment of the crisis of acute appendicitis. SCHWARTZ. *Paris méd.*, 1913, No. 29.

Appendicitis associated with abscess of the cæcal wall. 2. Galactorrhœa and amenorrhœa. BILSTED. *Ugesk. f. Læger*, Kjøbenhavn., 1913, lxxv, No. 26.

Appendicitis operated within thirty hours after its incipency. DELASSUS. *J. d. sc. méd. de Lille*, 1913, xxxvi, No. 23.

A case of herniary appendicitis. FOISY. *Arch. méd.-chir. de Province*, Poitiers, 1913, viii, No. 5.

The appendix and tuberculosis. BÉRARD and ALAMARTINE. *Lyon chir.*, 1913, ix, No. 6.

A case of appendix abscess. S. R. ROSS. *Med. Press & Circ.*, 1913, xcv, 663.

A case of associated recent elastic incarceration and gangrene of the vermiform appendix and an intestinal flexure. ARTHUR WAGNER. *Zentralbl. f. Chir.*, 1913, xl, 902.

Carcinoma and carcinoïd of the appendix. FRANZ ALFONS ROGG. *Ztschr. f. Krebsforsch.*, 1913, xiii, 12.

Cylindrical cell carcinoma of the vermiform appendix. EDUARD MILOSLAVICH. *Frankf. Ztschr. f. Path.*, Wiesb., 1913, xiii, 138.

Diverticuli of the appendix. TEKHOIROFF. *Vrach. Gaz.*, St. Petersburg., 1913, xx, No. 18.

Physiological pathology of the large intestine, especially considered from the surgical point of view. HUSTIN. *J. méd. de Brux.*, 1913, xviii, No. 24.

The surgical colon. A. L. BLESSE. *Proctologist*, 1913, vii, 57.

Anatomical consideration of ligamentous formations about the proximal end of the large intestine; ligamentum varioforme. M. M. RJESANOFF. *Chirurgia*, 1913, xxxiii, 126. [397]

Acquired diverticuli of the large intestine and their rôle in pathology. CADE, MARTIN and MOURGUES. *Paris méd.*, 1913, No. 27.

Colic stasis caused by deformities of the colon; symptomatic typhlectasis; surgical treatment. LARDENNOIS. *Presse méd.*, Par., 1913, xxi, No. 47.

Chronic intestinal stasis. W. A. LANE. *Surg., Gynec. & Obst.*, 1913, xvi, 600.

Intestinal ptosis producing intestinal stasis from the orthopedic viewpoint. ROBERT CAROTHERS. *Lancet-Clin.*, 1913, cix, 654.

Orthopedic principles in the treatment of abdominal visceroptosis and chronic intestinal stasis. GOLDTHWAIT. *Surg., Gynec. & Obst.*, 1913, xvi, 587. [397]

Chronic constipation; its surgical treatment. PERFOUX. *Arch. méd.-chir. de Province*, Poitiers, 1913, viii, No. 5.

The operative treatment of severe obstipation. SCHMIEDEN. *Arch. f. klin. Chir.*, 1913, ci, No. 3.

The initial phases of cancer of the large intestine. MATHIEU. *Gaz. d. hôp.*, Par., 1913, lxxxvi, No. 60.

Abdominal incisions and intestinal anastomosis in the treatment of carcinoma of the colon. ERNEST MAYLARD. *Glasgow M. J.*, 1913, lxxix, 401. [398]

Gas cysts of the intestine. PERCY R. TURNURE. *Ann. Surg.*, Phila., 1913, lviii, 811. [398]

The value of complete physiological rest of the large bowel in the treatment of certain ulcerative and obstructive lesions of this organ, with description of operative technique and report of cases. JOHN YOUNG BROWN. Surg., Gynec. & Obst., 1913, xvi, 610. [399]

X-ray diagnosis of ulcerous colitis. KIENBOCK. Fortschr. a. d. Geb. d. Röntgenstr., 1913, xx, No. 3.

Ulcerative colitis, due to a flagellate parasite (the intestinal *Lamblia*); perforation, then an intestinal occlusion. FAIRISE and JACQUOT. Arch. d. mal. de l'appareil digest. et de la nutr., Par., 1913, vii, No. 6.

Colitis chronica gravis. T. ROSENHEIM. Deutsche med. Wchnschr., 1913, xxxix, 998. [399]

Hirschsprung's disease. MEYER. Med. Klin., 1913, ix, No. 24.

Report of a case of faecal tumor associated with Hirschsprung's disease. GRAHAM. Tr. Am. Proctol. Soc., 1913, June. [400]

Megacolon. GARCIA. Argentina med., Buenos Aires, 1913, xi, No. 23.

Late conditions after exclusion of the colon by means of ileosigmoidostomy. VON BECK. Beitr. z. klin. Chir., 1913, lxxxiv, 338. [400]

Dilated and mobile sigmoid colon. KATZ. Terap. Obozrenie, Odessa, 1913, vi, No. 9.

Diverticulitis of the sigmoid. ARTHUR D. DUNN. Proctologist, 1913, vii, 66.

The beginning of the atypical neo-formations in the rectum and the sigmoid flexure. LIBENSKY. Ztschr. f. klin. Med., 1913, lxxvii, 355. [401]

Carcinoma of the sigmoid flexure the size of a fist. JENCKEL. München. med. Wchnschr., 1913, lx, 1515.

Cancer of the pelvic colon. MATHIEU. Gaz. d. hôp., Par., 1913, lxxxvi, No. 66.

Dysenteric rectitis and chlorhydrate of emetin. VALENCE. Bull. méd., Par., 1913, xxvii, No. 49.

Treatment of amebic dysentery with emetin. G. BAERMANN and H. HEINEMANN. München. med. Wchnschr., 1913, lx, 1132. [401]

Polypus of the rectum of at least thirty years' standing. GUIBE. Bull. et mém. Soc. anat. de Par., 1913, lxxxviii, 192.

Rectal prolapse treated by colopexy and peri-anal wiring; on the coexistence of rectal and genital prolapse; on hysterocolopexy. R. PROUST. Bull. et mem. Soc. de chir. de Par., 1913, xxxix, 637. [401]

Rectal section for pelvic abscess in men. MACLAREN. J.-Lancet, 1913, xxxiii, 254. [401]

Amputation of the rectum under exclusion of the pelvic colon. KELLING. Zentralbl. f. Chir., 1913, xl, No. 24.

A modern operation for rectal fistula. O. R. VON BONNEWITZ. J. Am. Inst. Homœop., 1913, v, 1258.

Two cases of ano-rectal malformation. MÜLLER. Lyon chir., 1913, ix, No. 6.

Anal imperforations. KIRMISSON. J. d. praticiens, Par., 1913, xxvii, No. 25.

Autoplasty with flaps of fat in anal fistula. DELOIRE. Bull. et mem. Soc. de chir. de Par., 1913, xxxix, 889. [402]

A method of operating on fistula without cutting muscular tissue. BARNES. Tr. Am. Proctol. Soc., 1913, June. [402]

Diagnosis of hæmorrhoids and the rectal sensation. SCHWARTZ. Paris méd., 1913, No. 26.

A further consideration of Sir Charles Ball's operation for internal hæmorrhoids. ZOBEL. Tr. Am. Proctol. Soc., 1913, June. [402]

Internal hæmorrhoids. CHAS. J. DRUBECK. Merck's Arch., 1913, xv, 171.

Sphincteric atrophy; causes, consequences and treatment. JACKSON. Tr. Am. Proctol. Soc., 1913, June.

Further observations on pruritis ani; its probable etiologic factor; results of treatment. MURRAY. Tr. Am. Proctol. Soc., 1913, June. [402]

The significance of symptoms of pain in the diagnosis of diseases of the digestive apparatus. REJCHMAN. Med. i. kron. lek., 1913, xlviii, Nos. 23 and 24.

Radiology of the digestive apparatus in 1912. GLÉNARD. Arch. d. mal. de l'appareil digest. et de la nutr., Par., 1913, vii, No. 6.

Generalization of melanotic tumors of the digestive tract. SAVY and BONNET. Arch. d. mal. de l'appareil digest. et de la nutr., Par., 1913, vii, No. 5.

Early diagnosis of carcinoma of the digestive tract. SCHÜTZ. Wien. klin. Wchnschr., 1913, xxvi, No. 26.

Experimental contribution on the circular repair of the intestinal tract by the employment of skin. K. K. WEDENSKI. Chir. Arch. Vellaminova, St. Petersburg., 1913, xxix, 263.

Reply to Hohlbaum's article concerning the question of iodization in operations on the gastro-intestinal tract. E. L. FIEBER. Zentralbl. f. Chir., 1913, xl, 720.

Liver, Pancreas, and Spleen

Functional examination of the liver. ISAAC. Berl. klin. Wchnschr., 1913, l, No. 25.

Retardation of the pulse in traumatism of the liver. KIRCHENBERGER. Wien. klin. Wchnschr., 1913, lxiii, No. 25.

Hæmostatic effect of muscle tissue in injuries of the liver. OPOKIN and SCHLAMOFF. Arb. a. d. chir. Klin. d. Prof. S. Fedoroff a. d. Milit. med. Akad., St. Petersburg., 1913, vii, 91. [403]

Passive congestion of the liver caused by hepatic colic. CASTAIGNE. Bull. méd., Par., 1913, xxvii, No. 45.

Casuistic and experimental contribution on the rupture of the liver and the bile-ducts. O. ORTH. Arch. f. klin. Chir., 1913, ci, 369.

Solitary cysts of the liver. HENRY NORRIS. Ann. Surg., Phila., 1913, lvii, 805. [404]

Atavistic origin of abscesses of the liver. CLARA REINIGER. Frankf. Ztschr. f. Path., Wiesb., 1913, xiii, 103.

Abscess of the liver presenting an abnormal symptomatology. GULLON. Clinique, Par., 1913, viii, No. 23.

A series of twenty personal cases of abscesses of the liver in tropical countries. PERVES and OUDARD. Arch. de méd. et de pharm. nav., Par., 1913, xcix, No. 5.

Carcinoma of the liver in an Australian aboriginal. THOMAS BANCROFT and B. CLELAND. Australas. M. Gaz., 1913, 465.

A new method for resection of the liver, with employment of free transplantation of fascia. KORNEW and SCHAACK. Zentralbl. f. Chir., 1913, xl, No. 24.

Radical operation on account of alveolar echinococcus of the liver. W. M. MYSCH. Chir. Arch. Vellaminova, St. Petersburg., 1913, xxix, 175.

The origin of gall-stone. A. BACMEISTER. Ergebn. d. inn. Med. u. Kinderh., 1913, xi, 1.

Pathogenesis of biliary lithiasis. FLANDIN. Arch. d. mal. de l'appareil digest. et de la nutr., Par., 1913, vii, No. 5.

A case of cholelithiasis; expulsion of the stone by vomiting. UBEDA and SARACHAGA. Rev. de med. y cir. pract., Madrid, 1913, xxxvii, No. 1268.

Cholelithiasis and cholecystitis during childhood and its treatment. KHAUTZ. Zentralbl. f. d. Grenzgeb. d. Med. u. Chir., 1913, xvi, 545. [404]

Cholecystectomy in cholelithiasis; indications and results. G. BACHY. Thèse de doct., Par., 1913. [405]

Anatomical, pathological and clinical study of a case of, cholecystitis. Poddighe. Riforma med., 1913, xxix, No. 25.

Suprapubic fistula after post-typhoid suppurative cholecystitis; cholecystectomy; recovery with persistency of the bacilli in the stools. JACOB. Bull. et mem. Soc. de chir. de Par., 1913, xxxix, 879. [405]

Formation of an artificial choledochus by means of a drainage tube. FRITZ CAHEN. Deutsche Ztschr. f. Chir., 1913, cxii, 331.

The employment of the omentum for hæmostasis in extirpation of the gall-bladder. L. STUCKEY. Verhandl. d. wiss. Ver. d. Ärzte d. städt. Obuchow-Krkh., St. Petersburg, 1913, xxii, 43. [405]

Inhibitive action of bile on bacillus coli. E. O. JORDAN. J. Infect. Dis., 1913, xii, No. 3. [405]

Primary carcinoma of the ampulla of Vater. ROGER and LAPEYRE. Arch. d. mal. de l'appareil digest. et de la nutr., Par., 1913, vii, No. 5.

Benign tumors of the bile-ducts. SAVY, BONNET and MARTIN. Lyon chir., 1913, ix, No. 6.

Typhoid infection of the bile-ducts in aplasia of the gall-bladder. STEFAN ZARZYCKI. Wien. klin. Wchnschr., 1913, xxvi, 798.

Ascariasis of the bile-ducts. LENORMANT. Presse méd., Par., 1913, xxi, No. 49.

Diagnosis and treatment of affections of the pancreas. ALBERT WOLFF. Berl. allg. med. Verl.-Anat., 1913. [405]

Affections of the pancreas and their treatment. SOHNHEIM. Pract. Vrach, St. Petersburg, 1913, xii, Nos. 18 and 20.

Sub-acute hæmorrhagic pancreatitis; intervention; cure. VINCENT and MAURY. Bull. méd. de l'Algérie, Alger, 1913, xxiv, No. 10.

Three cases of acute pancreatitis. KOZLOVSKY. Russk. Vrach, St. Petersburg, 1913, xii, No. 21.

Diagnosis and treatment of acute pancreatitis. VON REYHER. St. Petersburg. med. Ztschr., 1913, xxxviii, No. 11.

Pancreatic cysts. R. C. BRYAN. Va. M. Semi-Month., 1913, xviii, 114.

Effects of ligature of the pancreatic canal in the rabbit. WATERMANN. Nederl. Tijdschr. v. Geneesk., Amst., 1913, i, No. 22.

A case of free transplantation of the omentum in a stab wound of the spleen. LANGE. Verhandl. d. wiss. Ver. d.

Ärzte. d. städt. Obuchow-Krkh., St. Petersburg, 1913, xxii, 31. [406]

The hæmostatic action of the adipose tissue in wounds of the abdominal viscera. POLIÉNOFF and LADIJUNE. Vrach. Gaz., St. Petersburg, 1913, xx, No. 21.

Giant tumor of the spleen. FRIEDRICH. Monatschr. f. Geburtsh. u. Gynäk., 1913, xxxviii, 115.

Contribution to the knowledge of Banti's disease. GRUTZNER. Beitr. z. klin. Chir., 1913, lxxxv, 131.

Banti's disease in childhood; two cases of the disease in earliest infancy. D'ESPINE. Arch. f. Kinderh., 1913, lx-lxi, May.

A case of Banti's disease of luetic origin. URRUTIA. Rev. clin. de Madrid, 1913, ix, 329.

Modern surgery of the spleen. F. MICHELSSON. Ergebn. d. Chir. u. Orthop., 1913, vi, 480. [406]

Splenectomy in malarial affection of the spleen. KOPYLOW. Arch. f. klin. Chir., 1913, ci, No. 3.

Clinical observations concerning twenty-seven cases of splenectomy. H. Z. GIFFIN. Am. J. M. Sc., 1913, cxlv, 781. [407]

Extirpation of the spleen and the left kidney because of trauma. R. MÜHSAM. Deutsche med. Wchnschr., 1913, xxxix, 1044.

The effect of ablation of the spleen on nutrition. RICHET. J. de physiol. et de pathol. gén., Par., 1913, xv, No. 3.

Miscellaneous

Situs viscerum inversus totalis. C. ZENONI. Osp. mag., Milano, 1913, i, 236.

A case of transverse position of the viscera. JONKERS. Nederl. Tijdschr. v. Geneesk., Amst., 1913, i, No. 21.

Abdominal pain. GEO. J. WEITZ. J. Mo. St. M. Ass., 1913, ix, 406.

Abdominal pain areas. DESCOMPS and BROUSSE. Paris méd., 1913, No. 26.

Abdominal diagnosis. RATTERMANN. Lancet-Clin., 1913, cix, 676.

Ten years of abdominal surgery. DOCQ. Ann. de la policlin. centrale de Brux., 1913, xiii, No. 4.

SURGERY OF THE EXTREMITIES

Diseases of Bones, Joints, Muscles, Tendons— General Conditions Commonly Found in the Extremities

Clinical and experimental researches on bone formation. J. KOGA. Kyoto-Igaku-Zossi, 1913, ix, Nos. 2 and 3.

Anatomical findings in imperfect osteogenesis. KARDAMATIS. Virchow's Arch. f. path. Anat. u. Physiol. u. f. klin. Med., 1913, cxii, No. 3.

Bone and joint lesions and their treatment. H. G. TYMMS. Australas. Med. Gaz., 1913, xxxiii, 615.

Action of the X-ray on the development of callus; comparative study of radiographic and microscopic aspects of callus. CLUZET and DUBREUIL. J. de physiol. et de pathol. gen., Par., 1913, xv, 327. [408]

Köhler's malady of the navicular bone of the foot in children is not a fracture. A. KÖHLER. Arch. f. klin. Chir., 1913, ci, 560.

Röntgen-ray findings in epicondylitis of the humerus. BLECHER. Fortschr. a. d. Geb. d. Röntgenstr., 1913, xx, 239.

Osteomyelitis due to mixed infections. HAMANT and PIGACHE. Gaz. d. hôp., Par., 1913, lxxxvi, No. 71.

Acute osteomyelitis and osteoplastic surgery in childhood; a study based on the complete material of the Kaiser-und-Kaiserin-Friedrich Hospital for Children for the period of its existence, 1890-1912. WACHSNER. Arch. f. Kinderh., 1913, lx-lxi, May.

Spontaneous fractures in osteomyelitis. ATHANESESCO. J. de chir. de Bucarest, 1913, i, No. 1.

The clinical picture of fibrous osteitis. THERSTAPPEN. München. med. Wchnschr., 1913, lx, No. 25.

Deforming osteochondritis in youth. PERTHES. Arch. f. klin. Chir., 1913, ci, No. 3.

Secondary hyperplastic porotic osteoperiostitis. E. GRAFE and P. SCHNEIDER. Beitr. z. klin. Anat. u. z. allg. Path., 1913, lvi, 231.

Experimental syphilitic periostitis associated with bone caries. VANZETTI. Gior. d. r. Accad. di med. di Torino, 1913, lxxvi, Nos. 1-2.

A case of "syphilitic periostitis" cured by salicylates. E. H. GOODMAN. Boston M. & S. J., 1913, clxviii, 927.

The relation of trauma to bone tuberculosis. H. A. WILSON and R. C. ROSENBERGER. N. Y. M. J., 1913, cxvii, 1222.

- Treatment of tubercular hip disease. ARTHUR STEINDLER. Iowa M. J., 1913, xix, 610.
- The use of tuberculin in osseous tuberculosis in children. MARCHARD. Rev. méd. de la Suisse romande, 1913, xxxii, 333. [408]

- Experiences with Stoffel's operation in spastic paralysis. HOHMANN. München. med. Wchnschr., 1913, lx, No. 25.
- Plexus grafts. KATZENSTEIN. Berl. klin. Wchnschr., 1913, l, No. 25.

DISEASES AND SURGERY OF THE SKIN, FASCIA, APPENDAGES

Excessive thickening of Thiersch grafts caused by a component of scarlet red (amidoaxotoluol). J. S. DAVIS. *Bull. Johns Hopkins Hosp.*, 1913, xxiv, 178.

The occurrence of cancerous changes in benign new-growths of the skin. R. L. SUTTON. *Am. J. M. Sc.*, 1913, cxlv, 819. [418]

A case of endothelial sarcoma of the skin. MARTINOTTI. *Virchow's Arch. f. path. Anat. u. Physiol. u. f. klin. Med.*, 1913, ccxii, No. 3.

Pseudo-botryomycotic fungoid angioma of the skin. E. AIEVOLI. *Gazz. internat. di med., chir.*, 1913, No. 20, 460.

Ethyl chloride in the treatment of cutaneous epithelioma. HAROLD SEIDELING. *Lancet*, Lond., 1913, clxxxiv, 1663.

Ossification of calcinated cutaneous epithelioma. S. SALTYSKOW. *Zentralbl. f. allg. Pathol. u. pathol. Anat.*, 1913, xxiv, 481.

The treatment of lupus. DREUW. *Allg. wien. med. Ztschr.*, 1913, lviii, 244.

Skin grafting. J. CULBERTSON. *J. Okla. M. Ass.*, 1913, vi, 16.

Skin grafting. CHAS. S. WHITE. *Va. M. Semi-Month.*, 1913, xxviii, 6.

Homoeoplastic and heteroplastic transplantation of skin in amphibia, with special consideration of morphosis. R. WEIGL. *Arch. f. Entwicklungsmech. d. Organismen*, 1913, xxxvi, 595.

A change in the color of the hair after the transplantation of skin. GEORG SCHÖNE. *Ztschr. f. d. ges. exp. Med.*, 1913, i, 444.

Implantation of skin instead of plastic grafts of fascia. LÖWE. *München. med. Wchnschr.*, 1913, lx, No. 24.

Transplantation of fasciæ. SCHMID. *Gynäk. Rundschau*, 1913, vii, No. 13.

Free transplantation of aponeurotic flaps. GOLDMANN. *Przegl. chir. i ginek.*, 1913, viii, No. 3.

MISCELLANEOUS

Clinical Entities—Tumors, Ulcers, Abscesses, etc.

Tumors. KELLING. *Zentralbl. f. Chir.*, 1913, xl, 865.

Multiple tumors. VENOULETTE. *Russk. Vrach, St. Petersburg.*, 1913, xii, No. 21.

Malignant tumors from the biologic standpoint. SYKOFF and NENJUKOFF. *Novoje v Med.*, 1913, vii, 65. [418]

A new case of malignant tumor produced by a radio-dermatitis developed experimentally in a white rat. MARIE, GLUNET and RAULOT-LAPOINTE. *Bull. de l'ass. française p. l'étude du cancer.*, 1913, v, 125.

The relation of staphylococcus aureus to malignant tumors. MARICONDA. *Policlin.*, Roma, 1913, xx, No. 24.

A plea for a more conservative treatment of malignant growths. R. H. BOGGS. *Am. Quart. Röntgen.*, 1913, iv, 199.

Cancer statistics from the city of St. Petersburg for the years 1901-1910. N. G. TOITSCHKIN. *Dissertation*, St. Petersburg, 1913.

Forms of carcinoma prevalent in Norway. MUNCH SØEGAARD. *Ztschr. f. Krebsforsch.*, 1913, xiii, 89.

The microscopic examination of fresh tissues for the diagnosis of early cancer. L. B. WILSON. *St. Paul M. J.*, 1913, xv, 274.

The significance of lues for the development of cancer. LEDERMANN. *Wien. klin. Rundschau*, 1913, No. 25.

Heam-Uro-Chrome: A new laboratory test for cancer and sarcoma; also a method of separating bile acids and pigment with the application of Torquay's test, indican being obtained if present; a preliminary report. THEODORE G. DAVIS. *Am. J. M. Sc.*, 1913, cxlv, 857.

Progress in the treatment of cancer. F. WEBER. *St. Petersburg. med. Ztschr.*, 1913, xxxviii, 112.

Surgical treatment of cancer. LIZCANO. *Siglo med.*, Madrid, 1913, No. 3104.

Results at present obtained by the surgical treatment of cancer. DUPUY and FRENELLE. *Par. chir.*, 1913, v, No. 3.

General principles of the surgical treatment of cancer. JOHN A. HARTWELL. *N. Y. M. J.*, 1913, xcvi, 26.

The need of post-surgical treatment in cancer. COLE and HOLDING. *Am. Quart. Röntgen.*, 1913, iv, 213.

An etiological factor in carcinoma and its possible influence on treatment. H. W. NOWELL. *Boston M. & S. J.*, 1913, clxviii, 838. [419]

May carcinoma heal spontaneously? A. THEILHABER. *Deutsche med. Wchnschr.*, 1913, xxxix, 1314.

The influence of the extirpation of some glands of internal secretion on the development of sarcoma in the dog. KORENTCHEWSKY. *Russk. Vrach, St. Petersburg.*, 1913, xii, No. 18.

Malignant chorio-epithelioma; an anatomical, pathological and etiological study. PROUST and BENDER. *Rev. de gynéc. et de chir. abdom.*, Par., 1913, xx, Nos. 4-5.

Chorion-epithelioma; a clinical study. POLOSSON and VIOLET. *Rev. de gynéc. et de chir. abdom.*, Par., 1913, xx, Nos. 4-5.

Myeloma. F. SYSSOJEFF. *Chir. Arch. Veljaminova*, 1913, xxix, 348. [420]

Peculiar action of foreign bodies. C. SULTAN. *München med. Wchnschr.*, 1913, lx, 1038.

Shock. A. W. COLCORD. *Internat. J. Surg.*, 1913, xxvi, 209.

The transplantation of tissue as a method of scientific and medical research. GEORG SCHÖNE. *Naturwissenschaften*, 1913, i, 489.

New researches on the independent life of tissues and organs. CARREL. *Berl. klin. Wchnschr.*, 1913, i, No. 24.

Hodgkin's disease, its etiology and pathology. E. E. WUTKE. *Iowa M. J.*, 1913, xix, 614.

The histology of small Bilharzian concretions. E. PEISTER. *Ztschr. f. Urol.*, 1913, vii, 521.

A case of trichinosis with autopsy. E. P. BERNSTEIN. *Med. Rec.*, 1913, lxxxiii, 1169.

Sporotrichosis. B. W. RHAMY and W. W. CAREY. *J. Indiana St. M. Ass.*, 1913, vi, 274.

A case of gummous sporotrichosis. BIERER. *Arch. de méd. et de pharm. mil.*, Par., 1913, lxi, No. 6.

A study of actinomycosis. F. E. MCKENTY. *Am. J. M. Sc.*, 1913, cxlv, 835.

Tetanus. A. F. KINGSLEY. *J. Mich. St. M. Soc.*, 1913, xii, 322.

Persulphate of soda in the treatment of tetanus. BRON. *Bull. méd. de l'Algérie, Alger*, 1913, xxiv, No. 9.

The rational treatment of tetanus, with a report of twenty-three cases from the Episcopal Hospital, Philadelphia. A. P. C. ASHURST and R. L. JOHN. *Am. J. M. Sc.*, 1913, cxlv, 806.

The surgery of leprosy. T. L. SANDES. *South African M. Rec.*, 1913, xi, 229.

The existence of a new gland of internal secretion. PENDE. *Riforma med.*, 1913, xxix, No. 22.

Sera, Vaccines and Ferments

A new method of serum diagnosis. W. PFEILER and G. WEBER. *Berl. tierärztl. Wchnschr.*, 1913, xxix, 449.

Diagnosis of surgical tuberculosis by the "focal" tuberculin reaction. PIERI. *Rev. osp.*, Roma, 1913, iii, No. 10.

Observation on "diagnostic" tuberculin. N. D. BARDSWELL. *Lancet*, Lond., 1913, clxxxiv, 1581.

The present status of the tuberculin tests. CHAS. B. SLADE. *Med. Rec.*, 1913, lxxxiii, 1079.

The present status of tuberculin and its therapeutic limitations. J. RITTER. *Illinois M. J.*, 1913, xxiii, 638.

The clinical, morphological, and experimental investigations in regard to local tuberculin reactions caused by local injections in tuberculosis of the skin. F. J. ROSENBAACH. *Ztschr. f. Hyg. u. Infektionskrankh.*, 1913, lxx, 539.

Experiments in regard to the nature of the tuberculin reaction. PAUL T. MÜLLER. *Ztschr. f. Immunitätsforsch.*, 1913, xviii, 185.

The treatment of surgical tuberculosis with Rosenbach's tuberculin. H. MEYER. *Beitr. z. klin. Chir.*, 1913, lxxxv, 28.

Methods of using the "Rosenbach" tuberculin. KARL DROWATSKY and ERICH ROSENBERG. *Deutsche med. Wchnschr.*, 1913, xxxix, 1241.

Further information in regard to the reaction of thermoprecipitin in tuberculosis. ANTONIO FAGINOLI. *München. med. Wchnschr.*, 1913, lx, 1480.

Comparisons of different anti-pneumococcus sera. BOEHKE and MOURIZ. *Bol. d. Inst. nac. de Higiene de Alfonso XIII*, 1913, ix, 1.

The value of the deviation of the complement after von Dungen in the diagnosis of malignant malformations. ANSELM. *Policlin.*, Roma, 1913, xx, No. 6.

Early diagnosis of carcinoma by means of the dialytic procedure after Abderhalden. LÜDKE. *Gaz. d. hôp.*, Par., 1913, lxxxvi, No. 65.

Abderhalden's reaction; the human ovum and cancer. LABBE. *Gaz. méd. de Nantes*, 1913, xxxi, No. 24.

Serodiagnosis of tumors after the method of von Dungen. P. A. PETRIDIS. *München. med. Wchnschr.*, 1913, lx, 1318.

Serodiagnosis of tumors by means of the complement fixation test. HALPERN. *München. med. Wchnschr.*, 1913, lx, 914.

The derivation of the constituents of serum which influence cancerous cells. FREUND and KAMNER. *Wien. klin. Wchnschr.*, 1913, xxvi, No. 25.

Physico-chemical researches on serum agglutination. P. SCHMIDT. *Arch. f. Hyg.*, München and Leipz., 1913, lxxx, 62.

The antitoxin treatment of tetanus. E. W. GIVEN. *Am. J. Surg.*, 1913, xxvii, 205.

Two cases of marked septicemia, cured by means of the antistreptococcic serum combined with fixation abscess. FUNCK-FRENTANO and ROULLAND. *Gynécologie*, Par., 1913, xvii, No. 4.

Serumtherapy in erysipelas. O. NEWTON. *Calif. Eclect. M. J.*, 1913, vi, 138.

Do results justify the use of phylacogens? C. R. METCALF. *Boston M. & S. J.*, 1913, clxviii, 26.

Vaccine therapy. I. E. COLGIN. *Southern M. J.*, 1913, vi, 367.

Sensitized vaccine in acute bacterial infection; results obtained in a series of cases. GORDON and OXON. *Lancet*, Lond., 1913, clxxxiv, 1795.

Observations of results from vaccination against tuberculosis. C. A. JULIAN. *Med. Rec.*, 1913, lxxxiii, 1059.

The treatment of cancerous subjects by means of vaccination. LEWIN. *Therap. d. Gegenw.*, Berl., 1913, liv, No. 6.

Principles of ferment methods; a textbook for physicians, chemists and botanists. JULIUS WOHLGEMUTH. Springer, Berl., 1913.

Studies of normal and pathological serum by Abderhalden's dialysis method. Studies of the specificity of the protective ferment. Second contribution: Studies of the serum of Basedow's disease, nephritis, and diabetes mellitus. A. E. LAMPE and L. PAPAZOLU. *München. med. Wchnschr.*, 1913, lx, 1533.

Experimental studies of the specificity of Abderhalden's proteolytic protective ferment. E. FRANK and F. ROSENTHAL. *München. med. Wchnschr.*, 1913, lx, 1425.

Immunity against pancreatitis. H. JOSEPH and J. PRINGSHEIM. *Mitt. a. d. Grenzgeb. d. Med. u. Chir.*, 1913, xxvi, 290.

Immunity against tuberculosis by natural selection. H. W. BLÖTE. *Ztschr. f. Tuberkul.*, 1913, xx, 151.

The antitryptic action of serum in anaphylaxis. J. ANDO. *Ztschr. f. Immunitätsforsch.*, 1913, xviii, 1.

Blood

The blood in surgery. BOLOGNESI. *Clin. chir.*, Milano, 1913, xxi, No. 5.

Hæmatogenous and obstructive icterus; experimental studies by means of the Eck fistula. G. H. WHIPPLE and C. W. HOOPER. *J. Exp. M.*, 1913, xvii, 593. [420]

A rapid change of hæmoglobin to bile pigment in the circulation outside of the liver. G. H. WHIPPLE and G. W. HOOPER. *J. Exp. M.*, 1913, xvii, 612. [420]

The technique of blood analysis. E. MÜNZER. *Med. Klin.*, Berl., 1913, ix, 716.

A new chamber for counting blood cells and a criticism of the methods of counting blood cells. W. ROERDANSZ. *Pflüger's Arch. f. d. ges. Physiol.*, 1913, clii, 81.

Studies of the Armeth method for determining the neutrophile blood picture, and the neutrophile blood picture in health. AXEL VON BONSDORFF. *Beitr. z. Klin. d. Tuberkul.*, 1913, v, 319.

Observations on the inter-sexual reaction of the blood in man and new researches on the inter-sexual reactions of the blood in the horse. LE LORIER and LE COINTE. *Gynécologie*, Par., 1913, xvii, No. 4.

The combining and immunizing substances in the red blood cells. Second communication. The antigen of blood. KARL LANDSTEINER and EMIL PRASEK. *Ztschr. f. Immunitätsforsch. u. exp. Therap.*, 1913, xvii, 363.

Changes in the blood and the hæmatopoietic organs after amputations and exarticulations. SCHAAK. *Russk. Vrach*, St. Petersburg, 1913, xii, 631.

Researches on the blood serum and the cerebro-spinal fluid of epileptics. CARLO TREVISANELLO. *Zentralbl. f. Bakteriol.*, 1913, lxix, 163.

The foreign bodies enclosed in leucocytes with polymorphous nuclei during surgical affections. NACCARONE. *Riforma med.*, 1913, xxix, Nos. 22 and 23.

The influence of different large doses of radium emanation upon the blood. GUDZENT and HUGEL. *Radium in Biol. u. Heilk.*, 1913, ii, 202.

Urban factors in the chlorotic anæmia of the new-born and its preventive treatment. P. F. ARMAND-DELILLE. *Rev. mens. de gynec., d'obst. et de pediatrie*, Par., 1913, viii, 102.

Anæmia of the lower part of the body. G. F. VON SAAR. *Ergebn. d. Chir. u. Orthop.*, 1913, vi, 1.

Intravenous injection of small quantities of human blood for the treatment of severe anæmia. WEBER. *München. med. Wchnschr.*, 1913, lx, 1307. [420]

Anæmia from the standpoint of the operating surgeon. HENRY T. BYFORD. *Chicago Med. Recorder*, 1913, xxxv, 319.

The present status of the treatment of hyperæmia. EUGEN JOSEPH. *Therap. d. Gegenw.*, 1913, liv, 241.

Intraperitoneal hæmorrhage caused by isolated rupture of a branch (arteria phrenica) of the hepatic artery. A. REINHARDT. *Deutsche Ztschr. f. Chir.*, 1913, cxxii, 309.

The employment of the Momburg tube in cases of hæmorrhage. VON SAAR. *Ergebn. d. Chir. u. Orthop.*, 1913, vi, 1. [421]

Arrest of hæmorrhage and treatment of wounds with coagulin Kocher-Fonio. ANTON FONIO. *Cor.-Bl. f. Schweiz. Ärzte*, 1913, xliii, 385. [421]

The checking of internal hæmorrhage by means of intravenous injection of grape sugar. SCHREIBER. *Therap. d. Gegenw.*, 1913, liv, 195. [421]

Hæmorrhage from the axillary artery three months after trauma; ligation of the artery; false Volkmann's ischæmic paralysis. FROELICH. *Rev. méd. de l'Est.*, 1913, xlv, 294. [421]

The successful treatment of hæmophilous hæmorrhages by means of the thermocautery. R. PARREIDT. *München. med. Wchnschr.*, 1913, lx, 1150.

Thrombus. ROBERT HANSEN. *Virchow's Arch. f. pathol. Anat. u. Physiol.*, 1913, ccxiii, 65.

Thrombosis of the portal artery. F. WALCKER. *Arch. a. d. Chir. Klin. d. Prof. Oppel*, St. Petersburg., 1913, iv, 158.

A report of a case of thrombosis of the inferior vena cava. T. WILLETT and E. W. MÄCHTLE. *J. Am. M. Ass.*, 1913, lx, 1878.

Traumatic venous thrombosis in the upper extremity. BAUM. *Deutsche med. Wchnschr.*, 1913, xxxix, 997. [422]

Infusions of sugar as a prophylactic against thrombosis. FRANZ KUHN. *Deutsche Ztschr. f. Chir.*, 1913, cxxii, 90.

Thrombophlebitis of the cavernous sinus of furunculosis origin. SITZEN. *Nederl. Tijdschr. v. Geneesk.*, Amst., 1913, i, No. 25.

A case of operated embolism of the femoral artery. KEY. *Wien. klin. Wchnschr.*, 1913, xxvi, No. 23.

Some experiments on transfusion of blood. DUBILLIER and LEBORGNE. *Écho méd. du Nord*, Lille, 1913, xvii, No. 25.

Direct transfusion of blood. GÖBELL. *München. med. Wchnschr.*, 1913, lx, 1574.

Regarding a case of direct transfusion of blood by end to end suture of the radial artery and basilic vein. JACOMET. *Bull. med.*, 1913, xxvii, 435.

The Wassermann reaction in the Johns Hopkins Hospital. R. H. MAJOR. *Bull. Johns Hopkins Hosp.*, 1913, xxiv, 175. [422]

Blood and Lymph Vessels

Rhythmical spontaneous contractions of arteries. O. B. MEYER. *Ztschr. f. Biol.*, 1913, lxi, 275.

Investigations in regard to the automatic movements of the arteries. HERMANN FULL. *Ztschr. f. Biol.*, 1913, lxi, 287.

A case of aneurism of the anominate arteries cured by extirpation. K. IMAI. *Deutsche med. Wchnschr.*, 1913, xxxix, 1147.

Aneurism of the popliteal artery; ligature of the femoral artery at the vertex of Scarpa's triangle; recovery. MORALES PEREZ. *Rev. de med. y cir. pract.*, Madrid, 1913, xxxvii, No. 1269.

Arteriorrhaphy. O'DAY. *Northwest Med.*, 1913, v, 154. [423]

Rupture of the vena cava caused by trauma. SCHMIEDEN. *Deutsche Ztschr. f. Chir.*, 1913, cxxii, 591.

A frequent cause of varicose veins in women. QUISERNE. *Arch. méd.-chir. de Normandie*, Le Havre, 1913, iv, No. 5.

A contribution on the operative treatment of varicose veins of the lower extremities. KUZMIK. *Beitr. z. klin. Chir.*, 1913, lxxxiv, 1.

The treatment of varicose veins by means of the circular incision. GIENITZ. *München. med. Wchnschr.*, 1913, lx, No. 23.

Vein sutures. DOBROVOLSKAIA. *Russk. Vrach*, St. Petersburg., 1913, xii, No. 18.

Two cases of vein grafting for the maintenance of a direct arterial circulation. J. H. PRINGLE. *Lancet*, Lond., 1913, clxxxiv, 1795.

Researches on transplantation of blood vessels. GIOVANNI CASTIGLIONI. *Beitr. z. path. Anat. u. z. allg. Path.*, Jena, 1913, lvi, 63.

Treatment of angiomas by means of heated air. VIGNAT. *Clinique*, Par., 1913, viii, No. 22.

The action of adrenalin upon the peripheral vessels. W. A. SWETSCHNIKOFF. *Dissertation*, St. Petersburg., 1913. [423]

The ingestion of bacteria by the subepithelial lymphatic glands in health. K. H. DIGBY. *Lancet*, Lond., 1913, clxxxiv, 4686.

Heteroplastic production of lymphoid tissue. GREGGIO. *Frankf. Ztschr. f. Path.*, Wiesb., 1913, xiii, No. 1.

Intradermal lymphatic varices in the inguino-crural region. JACOB. *Bull. et mem. Soc. de chir. de Par.*, 1913, xxxix, 606. [424]

Tuberculosis of the lymphatics. L. H. REICHELDERFER. *Va. M. Semi-Month.*, 1913, xxviii, 6.

Hodgkin's disease; lymphogranulomatosis. LACRONIQUE. *Gaz. d. hôp.*, Par., 1913, lxxxvi, No. 67.

Contributions to the knowledge of lymphangiomas. WALTHER MÜLLER. *Beitr. z. klin. Chir.*, 1913, lxxxiv, 511.

A case of lymphosarcoma treated by radium. TURNER. *Arch. Röntgen Ray*, 1913, xvii, 418.

Lymphangioplasty: Handley's method. PARKER SYMS. *Ann. Surg.*, Phila., 1913, lvii, 785. [424]

Elephantiasis of the lower limbs. JURASZ. *Zentralbl. f. Chir.*, 1913, xl, 925.

Drainage by means of a thread according to Handley in a case of elephantiasis. BYLIN-KOLOSSOWSKY. *Verhandl. d. wiss. Ver. d. Ärzte d. städt. Obuchow-Krkh.*, St. Petersburg., 1913, xxii. [425]

Poisons

Bacteriæmia. W. C. K. BERLIN. *Ophth. Rec.*, 1913, xxii, 564.

Toxæmia-septicæmia, pyæmia. A. J. BURKHOLDER. *Va. M. Semi-Month.*, 1913, xviii, 120.

The occurrence of tubercle bacilli in the blood. BACMEISTER. *Zentralbl. f. d. Grenzgeb. d. Med. u. Chir.*, 1913, xvi, 511.

A new spirochæta found in human blood. HELEN CHAMBERS. *Lancet*, Lond., 1913, clxxxiv, 4686.

Agchylostoma ceylanicum, a new human parasite. CLAYTON LANE. *Indian Med. Gaz.*, 1913, xlvi, 217.

Tetragenous septicæmia. J. BYERS and THOMAS HOUSTON. *Lancet*, Lond., 1913, clxxxiv, 4686.

The gonococcus. W. B. CHURCH. *Calif. Eclect. M. J.*, 1913, vi, 131.

Interrelations in the streptococcus group, with special reference to anaphylactic reactions. D. J. DAVIS. *J. Infect. Dis.*, 1913, xii, No. 3. [425]

A note on the behavior of the saprophytic cocci with regard to Gram's stain. I. J. KLIGLER. *J. Exp. M.*, 1913, xvii, 653.

Nitrate intoxication as a result of injections of Beck's bismuth paste. JENSEN. *München. med. Wchnschr.*, 1913, lx, No. 22.

Surgical Therapeutics

Camphorated oil in high doses in therapeutics. ARRIVAT and ROZIES. *Gaz. d. hôp., Par.*, 1913, lxxxvi, No. 66.

The effect of camphor in bacterial infection. K. E. BÖHNCKE. *Berl. klin. Wchnschr.*, 1913, l, 818.

Further experiences with carbolated camphor. CHLUMSKY. *Klin.-therap. Wchnschr.*, 1913, xx, No. 22.

Amylene carbamate—synonym aponal; a new hypnotic. S. HALLOWS. *Med. Press & Circ.*, 1913, cxlvi, 607.

Critical remarks on the hormonal treatment. BURIANEK. *Čas. lék. česk.*, Prague, 1913, lii, No. 18.

Notes on the technique of using thorium paste. L. DUNCAN BULKLEY. *Chicago Med. Recorder*, 1913, xxxv, 323.

Treatment of wounds by means of sugar and heated air douches. MONJARDINO. *Arch. med. contemp.*, 1913, xxxi, 161.

The action of collargol enemata in septic processes. WOLF. *Deutsche med. Wchnschr.*, 1913, xxxix, 944. [425]

Experiences with noviform. RUDOLF PATEK. *Deutsche med. Wchnschr.*, 1913, xxxix, 1204.

Synthetic L-suprarenin. K. L. STOLL. *Lancet-Clin.*, 1913, cix, 679.

Non-operative treatment of malignant disease. T. J. HORDER. *Clin. J.*, 1913, xlii, 145.

The non-operative treatment of malignant tumors. WERNER. *Novoje v med.*, St. Petersburg, 1913, vii, 464.

Non-surgical treatment of malignant neoplasms. WERNER. *Novje v med.*, St. Petersburg, 1913, vii, Nos. 8 and 9.

Intravenous injections of various substances in animal cancer. LEO LOEB and M. S. FLEISHER. *J. Am. M. Ass.*, 1913, lx, 1857.

Chemotherapeutic experiments on cancerous subjects with selenium-iodine-methylene-blue. BRAUNSTEIN. *Berl. klin. Wchnschr.*, 1913, l, No. 24.

The treatment of anthrax with salvarsan. MOKRZECKI. *München. med. Wchnschr.*, 1913, lx, 1089. [425]

Oil of cade in tibial ulcers. C. W. HAMLIN. *Ellingwood's Therap.*, 1913, vii, 208.

The use of mastisol on the operative field. F. HAENEL. *Zentralbl. f. Chir.*, 1913, xl, 863.

Surgical Anatomy

Form, position and changes of position of the bronchial branch in children. ENGEL. *Arch. f. Kinderh.*, 1913, lx-lxi, May.

Electrology

Radiotherapy. STRAUZ. *Med. Klin.*, 1913, ix, 876.

Modern Röntgen ray therapy; particularly surface therapy. F. M. MEYER. *Deutsche med. Wchnschr.*, 1913, xxxix, 1508.

The basis of röntgenotherapy and radium therapy. W. D. BUTCHER. *Strahlentherapie, Berl.*, 1913, ii, 396 and *Arch. Röntgen Ray, Lond.*, 1913, xviii, 16.

Physical, chemical and biological properties of thorium-X. KAHN. *Strahlentherapie, Berl.*, 1913, ii, No. 2.

The chemical and biological effect of radio-active substances. FALTA. *Strahlentherapie, Berl.*, 1913, ii, No. 2.

Radio-active substances and their therapeutic value. D. WALTER. *Fortschr. a. d. Geb. d. Röntgenstr.*, 1913, xx, 511.

General histological changes in the tissues under the influence of radio-activity. WICKHAM. *Berl. klin. Wchnschr.*, 1913, l, No. 23.

Histological, cytological and serological examination of guinea pigs treated with X-rays. FRÄNKEL and BUDDE. *Fortschr. a. d. Geb. d. Röntgenstr.*, 1913, xx, No. 4.

Cases which are refractory to X-rays. MEYER. *Strahlentherapie, Berl.*, 1913, ii, No. 2.

The pain reducing influence of Röntgen and radium rays. SIMONSON. *Strahlentherapie, Berl.*, 1913, ii, No. 2.

The normal measure of radium and the method of measuring radio-activity. STEFAN MEYER. *Strahlentherapie, Berl.*, 1913, ii, 533.

The measurement of thorium-X preparations. B. KEETMAN and M. MAYER. *Strahlentherapie, Berl.*, 1913, ii, 543.

Types of photochemical radiometers for measuring X-rays. ROBERT KIENBOCK. *Strahlentherapie, Berl.*, 1913, ii, 556.

Dosage, measurements and control of the X-ray and other agents in therapeutics. WM. B. SNOW. *Internat. J. Surg.*, 1913, xxvi, 199. [425]

Radium and mesothorium and their derivation products. BAEZA. *Med. Weekbl., Amst.*, 1913, xx, Nos. 11 and 12.

Experimental investigations on the deep action of Röntgen rays. KOLDE. *Strahlentherapie, Berl.*, 1913, ii, No. 2.

A case of late injury caused by deep röntgenotherapy. W. DIETERICH. *Fortschr. a. d. Geb. d. Röntgenstr., Hamb.*, 1913, xx, 159.

Physical and technical principles of deep penetrating X-ray treatment. DESSAUER. *Deutsche Gesellsch. f. Gynäk.*, Halle, 1913, May. [425]

A combined filter for obtaining a favorable distribution of superficial and deep rays. LEO MOSES. *Zentralbl. f. Röntgenstr., Radium u. verw. Geb.*, 1913, iv, 131.

A grating diaphragm to cut off secondary rays from the object. G. BUCKY. *Arch. Röntgen Ray, Lond.*, 1913, xviii, 6. [426]

Clinical findings on ulcers caused by X-rays. HAGER. *Strahlentherapie, Berl.*, 1913, ii, 642.

Radiotherapy of tumors. WERNER. *Strahlentherapie, Berl.*, 1913, ii, 614. [426]

A lecture on radium in the treatment of malignant disease. ROBERT KNOX. *Brit. M. J.*, 1913, i, 1196.

Cancer and its treatment by X-rays and high frequency electricity or diathermia. MÜLLER. *Strahlentherapie, Berl.*, 1913, ii, No. 2.

The treatment of cancer by means of Röntgen rays and mesothorium. KRÖNIG and GAUSS. *Deutsche med. Wchnschr.*, 1913, xxxix, 1233.

Results of mesothorium treatment of cancer. PINKUSS. *Berl. klin. Wchnschr.*, 1913, l, No. 24.

The relation between sarcoma and myoma with respect to röntgenotherapy. MÜLLER. *Strahlentherapie, Berl.*, 1913, ii, No. 2.

Röntgenotherapy of myomata. BERDEZ. *Fortschr. a. d. Geb. d. Röntgenstr.*, 1913, xx, No. 4.

Conservative surgery from a röntgenological standpoint. CHEVALIER JACKSON. *Am. Quart. Röntgen.*, 1913, iv, 209.

Direct combined examination of single radiograph and patient; the episcopo. W. COTTON. *Practitioner*, 1913, xc, 1006.

X-ray pictures with paper sensitive to light. LORENTZ. *Deutsche med. Wchnschr.*, 1913, xxxix, 896.

The automatic development of Röntgen ray plates. A. WEBER. München. med. Wchnschr., 1913, lx, 1264.

Hepatoptosis and X-rays. LETULLE. Presse méd., Par., 1913, xxi, No. 53.

Radiographic determination of the position of foreign bodies. GOLSTE. Russk. Vrach, St. Petersburg, 1913, xii, No. 22.

On the exact localization of foreign bodies in the human body. SCHINGAGLIA. Policlin., Roma, 1913, xx, No. 6.

Radiographic measurements of the movements of the shoulder. MIRAMOND DELLA ROQUETTE. Arch. d'électr. méd., exp. et clin., Bordeaux, 1913, xxi, No. 360.

The value of the data furnished by radiography in thoraco-abdominal affections. DELBET. J. d. praticiens, Par., 1913, xxvii, No. 25.

Decomposition of the solutions of radium and of radium emanations in the organism after their introduction into blood circulation. ENGELMANN. Med. Klin., Berl., 1913, ix, No. 25.

Fulguration after the method of Keating Hart. ROELOFS. Nederl. Tijdschr. v. Geneesk., Amst., 1913, i, No. 21.

Clinical contributions on accidents caused by electricity. MALY. Deutsche Ztschr. f. Nervenhe., Leipz., 1913, xlv, Nos. 4-5.

Heliotherapy. LYON. Clinique, Par., 1913, viii, No. 26.

Seaside heliotherapeutic treatment of surgical tuberculosis and tuberculosis of the bronchial glands. RICHARD and FELTEN. Berl. klin. Wchnschr., 1913, l, No. 23.

The employment of heliotherapy at the seaside of southern seas. ORAZIO PUPINI. Ztschr. f. Balneol., Klimatol. u. Kurort-Hyg., 1913, v, 719.

The employment of heliotherapy after interventions. AIMES. Progrès méd., Par., 1913, xlv, No. 22.

The Finsen light treatment at the London Hospital, 1900-1913. J. H. SEQUEIRA. Lancet, Lond., 1913, clxxxiv, 1655.

Military and Naval Surgery

Military surgery. G. M. BLECH. Am. J. Surg., 1913, xxvii, 224.

A singular bullet wound. HYMANS and VAN DER GOOT. Nederl. Tijdschr. v. Geneesk., Amst., 1913, i, No. 20.

The treatment of gun-shot wounds of the chest. A. L. BURNETT. Colo. Med., 1913, x, 196.

Brief remarks on gun-shot wounds of the abdomen, with report of cases. LINDSAY PETERS. J. South Car. M. Ass., 1913, ix, 141.

Bullet wounds of the liver with report of a case. H. FREUDENBERGER. Colo. Med., 1913, x, 179.

Gun-shot injuries of blood vessels. LOTSCH. Deutscher chir. Kong., 1913. [426]

Surgical Diagnosis

The importance of sciatic and lumbar neuralgia in the diagnosis of tuberculous inflammatory tumors of the pelvis. CAMERA. Policlin., Roma, 1913, xx, No. 22.

GYNECOLOGY

Uterus

Uterine affections. GUIAO. Imprensa med., Soa Paulo, 1913, xxi, No. 9.

Diseases of the uterus and the ovaries and psychoses. BOSSJ. J. akush. i jensk. boliez., St. Petersburg, 1913, xxviii, June.

A large coprolith enclosing the uterus and simulating a malignant tumor. ROMEO. Gazz. d. osp. e d. clin., Milano, 1913, xxxiv, 536. [427]

Uterine cancer. W. PIERSON. North Am. J. Homoeop., 1913, xxviii, 343.

An early diagnosis of cancer of the uterus, with report of an hysterectomy in an early case. A. C. HENDRIX. Canad. J. M. & S., 1913, xxxiii, 433.

The utility of exploratory curettage for the early diagnosis of uterine cancer. SIREDEY and LEMAIRE. Ann. de gynéc. et d'obst., Par., 1913, x, May.

The utility of cystoscopic examination in cancer of the cervix of the uterus. FRANCO. Arch. ital. di ginec., Napoli, 1913, xvi, No. 5.

A case of an extended carcinoma which grew through the rear wall of the uterus and penetrated to the rectum. OPITZ. Monatschr. f. Geburtsh. u. Gynäk., 1913, xxxviii, 403.

Recovery in a case of carcinoma of the uterus demonstrated by test-curettage. HESS. Deutsche med. Wchnschr., 1913, xxxix, 1038.

Chorio-epithelioma following hydatidiform mole and giving rise to intraperitoneal hæmorrhage from an extension in the right meso-salpinx. WILSON. Proc. Roy. Soc. Med. 1913, vi, Obst. & Gynec. Sect., 224. [427]

Adenomyositis of the uterus and of the rectum. M. RASPINI. Ginecologia, 1913, ix, 577. [427]

Contribution to the study of benign chorio-epitheliomas of the wall of the uterus and tubes. F. DAELS. Bull. de l'Acad. roy de méd. de Belg., 1913, xxvii, 175. [427]

Surgical treatment of uterine cancer. BOTIN. Rev. ibero-amer. de cienc. med., Madrid, 1913, xxix, No. 105.

Treatment of inoperable cancer of the cervix of the uterus; the present status of the question. ROZIES and ARRIVAT. Gaz. d. hôp., Par., 1913, lxxxvi, No. 70.

Complete removal of a uterine cancer by test curettage. P. PRYM. Deutsche med. Wchnschr., 1913, xxxix, 1247.

Bumm's recent results in the radical operation of uterine cancer. LASTARIA. Arch. ital. di ginec., Napoli, 1913, xvi, No. 5.

Means of improving the immediate results of the radical operation of uterine cancer by the abdominal path. DE BOVIS. Semaine méd., Par., 1913, xxxiii, No. 26.

Results of X-ray and mesothorium treatment of uterine carcinoma. E. BUMM. Deutsche Gesellsch. f. Gynäk., Halle, 1913, May. [428]

Röntgen ray and mesothorium treatment of myoma and carcinoma of the uterus. A. DÖDERLEIN. Deutsche Gesellschaft. f. Gynäk., Halle, 1913, May. [428]

A peculiarly shaped myomatous uterus. KÜSTNER. Deutsche Gesellschaft. f. Gynäk., Halle, 1913, May. [428]

Experiences with radiotherapy of myomata and of climacteric hæmorrhages of the uterus. EDLING. Fortschr. a. d. Geb. d. Röntgenstr., 1913, xx, No. 3.

X-ray treatment of myomata and fibrosis of the uterus. HIRSCH. Fortschr. a. d. Geb. d. Röntgenstr., 1913, xx, No. 4.

Partial myoma operations. FREUND. Deutsche Gesellschaft. f. Gynäk., Halle, 1913, May. [429]

Disappearance of a uterine fibroma, with conservation of menstruation; radiotherapeutic technique. CHARLIER. Bull. et mém. Soc. de radiol. méd. de Par., 1913, v, 111.

X-ray treatment of uterine fibroids, menorrhagia and metrorrhagia. SAMUEL STERN. Am. J. Obst., N. Y., 1913, lxvii, 1133.

Pathology and treatment of uterine hæmorrhage. B. WHITEHOUSE. Practitioner, Lond., 1913, xc, 952. [429]

Clinical notes on uterine hæmorrhage. HUBERT A. ROYSTER. Southern M. J., 1913, vi, 401.

The influence of the radium emanation on uterine hæmorrhages. OPITZ. Zentralbl. f. Gynäk., 1913, xxxvii, No. 22.

The thyrogenous etiology of hæmorrhagic metropathies. E. SEHRT. München. med. Wchnschr., 1913, lx, 961. [429]

The pathology of uterine casts passed during menstruation. W. B. BELL. Surg., Gynec. & Obst., 1913, xvi, 651. [429]

The forensic significance and the treatment of menstruation accompanied by psychic disturbances. HUGO BOAS. Arch. f. Kriminalanthropol., 1913, liii, 324.

Menstrual molimina; adult cases. CHISHOLM. J. Obst. & Gynec. Brit. Emp., 1913, xxiii, 389. [430]

Disturbed menstruation in psychosis. H. HAYMANN. Ztschr. f. d. ges. Neurol. u. Psychiatr., 1913, xv, 511. [430]

So-called idiopathic dysmenorrhœa and its treatment. DALCHE. Progrès méd., Par., 1913, xlv, No. 25.

The use of the "metranoikter" in the treatment of dysmenorrhœa and sterility. P. F. WILLIAMS. N. Y. M. J., 1913, xcvi, 1190.

Dysmenorrhœa and its treatment. ALBERT BLAU. Med. Klin., 1913, ix, 653. [430]

The treatment of amenorrhœa. ZOEPFRITZ. Deutsche Gesellschaft. f. Gynäk., Halle, 1913, May. [430]

A further consideration of the use of corpora lutea in the treatment of artificial menopause. C. A. HILL. Surg., Gynec. & Obst., 1913, xvi, 712. [431]

The treatment of endometritis. GEO. F. WARD. N. Y. M. J., 1913, xcvi, 1181. [431]

A case of uterus septus (diagnosed on the removal of the placenta). C. KÜHLMANN. Strassburg. med. Zeit., 1913, x, 177.

Inversion of the uterus, with a report of a case occurring during the puerperium and caused by a fibroid. WALTER C. JONES. Surg., Gynec. & Obst., 1913, xvi, 632. [432]

Retroflexion of the uterus. A. DONALD and W. F. SHAW. Practitioner, Lond., 1913, xc, 961. [432]

Removal of strain from the round ligaments while healing after correcting retroversion of the uterus. W. T. COUGHLIN. Surg., Gynec. & Obst. 1913, xvi, 712.

An unusual case of rupture of the uterus. ANDREWS. Proc. Roy. Soc. Med., 1913, vi, Obst. & Gynec. Sect., 272. [433]

Adnexal and Periuterine Conditions

The arrangement and distribution of the nerves in certain mammalian ovaries. ABEL and McILROY. Proc. Roy. Soc. Med., 1913, vi, Obst. & Gynec. Sect., 240. [433]

Cancerous transformation of cysts of the ovary. OULESKO-SHOGANOVA. Russk. Vrach, St. Petersburg., 1913, xii, No. 18.

Melanosarcoma of the ovary. BONDI. Wien. klin. Wchnschr., 1913, xxvi, No. 26.

Dermoid and teratoma. ROSENSTEIN. Monatschr. f. Geburtsh. u. Gynäk., 1913, xxxviii, 109.

Pseudomyxoma peritonei with involvement of the ovaries and appendix. B. RATHE. Monatschr. f. Geburtsh. u. Gynäk., 1913, xxxvii, 322. [433]

The rôle of ovarian disease in the production of sterility. GEO. W. KOSMAK. Bull. Lying-In Hosp., 1913, ix, 107.

The grafting of human ovaries. T. TUFFIER. J. de chir., 1913, x, 529. [433]

Transplantation of ovaries into foreign species. W. HARMS. Arch. f. Entwicklungsmech. d. Organismen, 1913, xxv, 748. [434]

Ovarian surgery during the year 1912. DANIEL. J. de chir. de Bucarest, 1913, i, No. 1.

The effect of castration on the hypophysis. RÖSSLE. München. med. Wchnschr., 1913, lx, 952. [434]

A case of chorio-epithelioma of the Fallopian tube following extra-uterine gestation. COPE and KETTLE. Proc. Roy. Soc. Med., 1913, vi, Obst. & Gynec. Sect., 247. [434]

Indications for operation in cystic adnexitis. P. LIZCANO. Siglo med., 1913, lx, 214.

A clinical lecture on salpingo-oöphoritis. T. G. STEVENS. Clin. J., 1913, xlii, 129.

Surgical treatment of pyosalpinx. S. ANDERSON. Ky. M. J., 1913, xi, 510.

Abdominal hysterectomy by anterior amputation in bilateral pyosalpinx. BARNSBY. Arch. mens. d'obst. et de gynec., Par., 1913, ii, No. 5.

Tuberculosis of the tube. JAYLE. Presse méd., Par., 1913, xxi, No. 51.

Fibrosarcoma of the broad ligament. J. JACOB. Zentralbl. f. Gynäk., 1913, xxxvii, 931.

The treatment of pus within the female pelvis. JAS. C. WOOD. N. Eng. M. Gaz., 1913, xlviii, 287.

Massive intraperitoneal hæmatoma of the pelvis. JAS. HARRAR. Bull. Lying-In Hosp., 1913, ix, 125.

External Genitalia

The surgical treatment of primary carcinoma of the vagina. POZSONYI. Budapesti orvosok ujsag, Sebeszet, 1913, ii, 16. [435]

Traumatic rupture of the vagina and resultant prolapse of the small intestine. F. VOGEL. München. med. Wchnschr., 1913, lx, 1326.

Fracture of the pelvis and laceration of the vagina. ADOLPH HOFFMANN. Deutsche med. Wchnschr., 1913, xxxix, 1285.

Incontinence of urine and vaginal prolapse. MURET. Rev. de gynec. et de chir. abdom., Par., 1913, xx, Nos. 4 and 5.

Creation of a vagina in case of the congenital absence of this canal by graft of a flexure of the intestine; operative technique. QUÉNU and SCHWARTZ. Rev. de chir., Par., 1913, xxxiii, No. 6.

Plastic repair of the vagina in the congenital absence of the organ. ALBRECHT. Deutsche Ztschr. f. Chir., 1913, cxix, Nos. 5 and 6.

The importance and value of the inverted T-incision in vaginal surgery. SAMUEL W. BANDLER. Med. Rec., 1913, lxxxiii, 1164. [435]

Bacilli of the vagina and internal infection. BONDY. Ztschr. f. Geburtsh. u. Gynäk., 1913, lxxviii, No. 2.

Leucorrhœa and gonorrhœa. C. D. R. KIRK. Ellingwood's Therap., 1913, vii, 207.

Practical considerations on vaginal injections in gynecology. DALCHE. Clinique, Par., 1913, viii, No. 23.

Vaginal irrigation under pressure in gynecological practice before vaginal operations and in the examination of prostitutes. DREUW. München. med. Wchnschr., 1913, lx, No. 25.

Esthiomene, or lupus vulvæ. KURG. J. Obst. & Gynec. Brit. Emp., 1913, xxiii, 353. [435]

Perineorrhaphy with the buried layer stitch. ROLAND HAZEN. *Internat. J. Surg.*, 1913, xxvi, 214. [436]

Primary and end results of the operative treatment of perineal lacerations, vaginal and uterine prolapse through restoration of the pelvic floor. SCHABAK. *Med. Rundschau*, 1913, xl, 630. [436]

The newer operations for restoration of the pelvic floor with an original technique for exposing and uniting the injured levatores ani and deep transversus perinei muscles. BARTON C. HIRST. *Am. J. Obst.*, N. Y., 1913, lxvii, 1148.

Miscellaneous

Cystoscopy and catheterization of the ureter as aids to diagnosis in gynecology. HORWITZ and IPATOFF. *Arb. a. d. geburtsh. gynäk. Klin.*, Prof. Redlich, St. Petersb., 1913, i, 41.

Extravesical opening of the ureter in women. J. P. HARTMANN. *Ztschr. f. gynäk. Urol.*, Leipzig, 1913, iv, 69. [436]

Incontinence of urine in women. H. A. KELLY. *Urol. & Cutan. Rev.*, 1913, xvii, 291.

Congenital malformation of the genital system in woman. PIETKIEWICZ. *Przegl. chir. i ginek.*, 1913, viii, No. 3.

A false diagnosis in a rare malformation of the internal genital organs. STRATZ. *Gynäk. Rundschau*, 1913, vii, No. 13.

Preventive phases of gynecology. J. H. HIDE. *Therap. Rec.*, 1913, viii, 183.

Experiences in the gynecological clinic of the Royal University of Munich with mesothorium and X-ray treatment of uterine carcinomata. VON SEUFFERT. *Strahlentherapie*, Berl., 1913, ii, No. 2.

X-ray treatment in gynecology. KREUZFUCHS. *Wien. med. Wchnschr.*, 1913, lxiii, No. 24.

X-ray treatment in gynecology. DOHAN. *Fortsch. a. d. Geb. d. Röntgenstr.*, 1913, xx, No. 4.

Radiotherapy in gynecology. D'HALLUIN. *J. d. sc. méd. de Lille*, 1913, xxxvi, No. 25.

Röntgenotherapy in gynecology. M. NEMENOW. *Fortschr. a. d. Geb. d. Röntgenstr.*, 1913, xx, 326.

Clinical experiences regarding the limits of erythema in gynecological deep radiotherapy by the use of strongly filtered rays. BORELL. *Strahlentherapie*, Berl., 1913, ii, No. 2.

Gynecological deep röntgenotherapy. GAUSZ. *Strahlentherapie*, Berl., 1913, ii, No. 2.

Clinical experiences regarding lesions of the skin in gynecological deep radiotherapy by the use of slightly filtered rays. ROMINGER. *Strahlentherapie*, Berl., 1913, ii, No. 2.

Experimental researches on gynecological deep radiotherapy. ROST and KRÜGER. *Strahlentherapie*, Berl., 1913, ii, No. 2.

Mesothorium as a substitute for rays in gynecology. H. VOIGTS. *München. med. Wchnschr.*, 1913, lx, No. 22. [437]

Methods of applying Röntgen rays in gynecology. S. G. SARETZKY. *Arb. a. d. geburtsh. gynäk. Klin. Prof. Redlich, St. Petersb.*, 1913, i, 113.

The action of the so-called gas bacillus upon the female genitalia. E. FRAENKEL. *Klin.-therap. Wchnschr.*, 1913, xx, 485. [437]

Contribution to the study of the localization of microorganisms in experimental septicæmia. U. SELLA. *Ann. di ostetr. e ginec.*, 1913, xxxv, 206. [437]

Intraperitoneal hæmorrhages of genital origin, but not due to pregnancy. GROSS and HEULEY. *Arch. mens. d'obst. et de gynec.*, Par., 1913, ii, No. 5.

Observations upon the formation of terata. EDW. A. SCHUMANN. *Am. J. Obst.*, N. Y., 1913, lxvii, 1159.

One gauze sponge removed from bladder, another from the vagina, months after a Dührssen operation for prolapse. HENRY D. FURNISS. *J. Am. M. Ass.*, 1913, lx, 1879.

The employment of fermentin tablets in gynecology. J. HIRSCHFELD. *Fortschr. d. Med.*, Berl., 1913, xxxi, 606.

The employment of iodine in gynecology. GAUGAIN. *Arch. méd. d'Algers*, 1913, xvii, No. 6.

The action of mesothorium upon genital tumors. KROEMER. *Deutsche Gesellsch. f. Gynäk.*, Halle, 1913, May. [438]

Further control of the morbidity and the mortality in abdominal operations for pelvic diseases. GEO. W. CRILE. *N. Y. St. M. J.*, 1913, xiii, 300.

Further clinical and etiological communications on pseudo-tuberculous ulcers of the female genitalia. SCHERBER. *Wien. klin. Wchnschr.*, 1913, xxvi, No. 26.

The operative treatment of old infiltrations. FALGOWSKI. *Deutsche Gesellsch. f. Gynäk.*, Halle, 1913, May. [438]

OBSTETRICS

Pregnancy and Its Complications

Multiple pregnancy, quadruplets. HENRY PEET. *Australas. M. Gaz.*, 1913, xxxiii, 615.

Quadruplets and their mothers. H. HAUSER. *München. med. Wchnschr.*, 1913, lx, 812. [439]

On the hypophysis in general and on its changes during pregnancy. GLINSKY. *Klin.-therap. Wchnschr.*, 1913, xx, No. 22.

Further contribution on the displacement of the cæcum during pregnancy. FÜTH. *Deutsche Gesellsch. f. Gynäk.*, Halle, 1913, May. [439]

Varicose veins and pregnancy. GRÜNFELD and ALLMEYER. *Med. Klin.*, Berl., 1913, ix, Nos. 22 and 23.

Tuberculosis and pregnancy. STUTZ. *Ztschr. f. Geburtsh. u. Gynäk.*, 1913, lxxviii, No. 2.

Cardiac disease and pregnancy. SELLHEIM. *Deutsche Gesellsch. f. Gynäk.*, Halle, 1913, May.

Diseases of the kidneys during pregnancy of women suffering from heart disease. R. JASCHKE. *Deutsche Gesellsch. f. Gynäk.*, Halle, 1913, May. [439]

Kidney and pregnancy. R. JASCHKE. *Deutsche Gesellsch. f. Gynäk.*, Halle, 1913, May. [439]

Heart and kidney affections during pregnancy. SCHMIDT. *Deutsche Gesellsch. f. Gynäk.*, Halle, 1913, May. [440]

Kidney disease and pregnancy. STOECKEL. *Deutsche Gesellsch. f. Gynäk.*, Halle, 1913, May. [440]

Kidney function in pregnancy and in the toxæmias of pregnancy. FETZER. *Deutsche Gesellsch. f. Gynäk.*, Halle, 1913, May. [440]

The function of the kidney in pregnancy and the eclamptic kidney. ECKELT. *Deutsche Gesellsch. f. Gynäk.*, Halle, 1913, May. [441]

The kidney of pregnancy and nephritis in graviditate. HOLZBACH. *Deutsche Gesellsch. f. Gynäk.*, Halle, 1913, May. [441]

- Medical treatment for weak labor during parturition. **HANS REINHARD.** Deutsche med. Wchnschr., 1913, xxxix, 747. [449]

The galvanization treatment of the uterus according to Bayer in conjunction with pituitrin as a means for the artificial induction of premature labor and labor at term. VOGELSBERGER. *Med. Klin.*, 1913, ix, 620. [449]

Indications for the high forceps operation. HERBERT OLD. *Va. M. Semi-Month.*, 1913, xxviii, 6.

Subcutaneous symphysiotomy of Frank. KEHRER. *Arch. f. Gynäk.*, 1913, xcix, 294. [450]

Puerperium and Its Complications

Three cases of symmetrical necrosis of the cortex of the kidneys, associated with puerperal eclampsia and suppression of urine. JARDINE and KENNEDY. *Lancet*, Lond., 1913, clxxxiv, 1291. [450]

A critical review of the medical and surgical treatment of puerperal eclampsia. E. G. ZINKE. *Am. J. Obst.*, N. Y., 1913, lxvii, 1065.

The results of new researches on puerperal fever. O. BONDY. *Monatschr. f. Geburtsh. u. Gynäk.*, 1913, xxxvii, 821.

Clinical and experimental investigations concerning the action of oxytocic substances during the puerperium. RÜBSAMEN. *München. med. Wchnschr.*, 1913, lx, 627. [450]

Differential diagnosis and treatment of puerperal infection. R. H. HUGGINS. *Penn. M. J.*, 1913, xvi, 695. [451]

Advanced treatment of puerperal infection. ROBT. T. GILLMORE. *J. Am. M. Ass.*, 1913, lx, 1955.

A case of puerperal infection cured by operation. BRIX. *München. med. Wchnschr.*, 1913, lx, No. 24.

Prophylaxis of puerperal infection. SCHWEITZER. *Deutsche Gesellsch. f. Gynäk.*, Halle, 1913, May. [451]

Puerperal tetanus. R. Worrall. *Australas. M. Gaz.*, 1913, xxxiii, 464.

Localizing peritonitis of puerperal origin. H. T. HICKS. *J. Obst. & Gynec. Brit. Emp.*, 1913, xxiii, 300.

The significance of post-partum hæmorrhages. SCHEFFZEK. *Monatschr. f. Geburtsh. u. Gynäk.*, 1913, xxxvii, 872.

Puerperal insanity. STODDART. *Clinical J.*, 1913, xliii, 189. [451]

Miscellaneous

The relations of affections of the heart to pregnancy, delivery and puerperium. FROMME. *Deutsche Gesellsch. f. Gynäk.*, Halle, 1913, May. [451]

Serum diagnosis of pregnancy. ZOEPPRITZ. *Deutsche Gesellsch. f. Gynäk.*, Halle, 1913, May. [452]

The biological diagnosis of pregnancy by the aid of the optic and dialysis methods. RÜBSAMEN. *Deutsche Gesellsch. f. Gynäk.*, Halle, 1913, May. [452]

The diagnosis of pregnancy by Abderhalden's method. POLANO. *Sitzungsber. d. physikal.-med. Ges.*, Würzb., 1913, ii, 23.

Abderhalden's dialytic procedure. LICHTENSTEIN. *Deutsche Gesellsch. f. Gynäk.*, Halle, 1913, May. [452]

Dry placental powder and its employment in Abderhalden's dialytic procedure for the diagnosis of pregnancy. V. L. KING. *München. med. Wchnschr.*, 1913, lx, 1198.

The sero-diagnosis of pregnancy by the dialysation method. C. F. JELLINGHAUS and J. R. LOSEE. *Bull. Lying-In Hosp.*, 1913, ix, 68.

The diagnosis of pregnancy by means of the dialysis and the optical method. EMIL ABDERHALDEN. *Gynäk. Rundschau*, 1913, vii, 467.

Studies of the reaction of Abderhalden's serum. B. ASCHNER. *Berl. klin. Wchnschr.*, 1913, l, 1243.

Abderhalden's pregnancy reaction. F. HEIMANN. *Berl. Klin.*, 1913, xxv, 1.

Artificial and natural conditions causing the Abderhalden reaction, and their significance. ERNST HEILNER and T. PETRI. *München. med. Wchnschr.*, 1913, lx, 1530.

Experimental research on the physiology of the hypophysis. SCHLIMPERT. *Deutsche Gesellsch. f. Gynäk.*, Halle, 1913, May. [453]

Clinical experiments with pituglandol. BASSET. *Med. Klin.*, Berl., 1913, ix, 457. [453]

Organotherapeutic value of adrenalin in pregnancy. ZANFROGINI. *Ann. di ostet. e ginec.*, Milano, 1913, xxxv, 247. [453]

The value of the caput succedaneum as a sign of "vital reaction." ZIEMKE. *Vierteljahrsschr. b. gerichtl. Med.*, 1913. [453]

Modern ecobolico with special reference to B-imidazoly-läthylamin. C. KOCH. *Zentralbl. f. Gynäk.*, 1913, xxxvii, 564. [453]

The diagnostic employment of the Röntgen rays in obstetrics. HEYNEMANN. *Ztschr. f. Geburtsh. u. Gynäk.*, 1913, lxviii, No. 1.

Pelvic measurement by means of X-rays. DESSAUER. *Deutsche Gesellsch. f. Gynäk.*, Halle, 1913, May. [453]

Diagnostic and therapeutic employment of aspiration, by means of the fontanelle, of obstetrical hæmorrhages of the new-born. HENSCHEN. *Zentralbl. f. Gynäk.*, 1913, xxxvii, No. 25.

The significance of meconium in dissections of the new-born. G. G. PERRANDO. *Riforma med.*, 1913, xxix, 325. [454]

The nutritive value of colostrum; a contribution on the nursing's requirement of energy during the first days of life. L. LANGSTEIN, F. ROTT and F. EDELSTEIN. *Ztschr. f. Kinderheilk.*, 1913, vii, 210.

The employment of extracts of the hypophysis in obstetrics and gynecology. METZGER. *Arch. mens. d'obst. et de gynec.*, Par., 1913, ii, 481.

Pituitrin in obstetrics. J. K. QUIGLEY. *N. Y. St. M. J.*, 1913, xiii, 317.

The casuistry of the action of pituitrin. GRUMANN. *München. med. Wchnschr.*, 1913, lx, 1436.

Pituitrin as an aid in labor. ALFRED DEUTSCH. *Wien. med. Wchnschr.*, 1913, lxiii, 1367.

Disinfection in obstetrics and manual detachment of the placenta. Remarks in regard to the work of C. Sievert. FRIEDRICH GAUS. *Deutsche med. Wchnschr.*, 1913, xxxix, 1363.

Placental infarct and intra-uterine under nourishment. TASSIUS. *Monatschr. f. Geburtsh. u. Gynäk.*, 1913, xxxvii, 869.

Complement deviation by corpus luteum secretion. J. T. SMITH. *Am. J. Obst.*, N. Y., 1913, lxvii, 1007.

Some obstetric observations pertaining to internal secretion. W. H. GOOD. *Am. J. Obst.*, N. Y., 1913, lxvii, 1100.

The toxicity of the urine during pregnancy, labor and puerperium. FRANZ. *Deutsche Gesellsch. f. Gynäk.*, Halle, 1913, May. [454]

Generation as influenced by intoxication. P. NACKE. *Ztschr. f. d. Neurol. u. Psychiatr.*, 1913, xvii, 474.

Further observations upon birth fractures. EDW. D. TRUESDELL. *Bull. Lying-In Hosp.*, 1913, ix, 103.

The intra-abdominal pressure in pregnancy. R. H. PARAMORE. *Lancet*, Lond., 1913, clxxxiv, 4686.

Lower arm type of obstetric (brachial) paralysis; report of a case. R. H. FOWLER. *Internat. J. Surg.*, 1913, xxvi, 196. [454]

On the pressure experienced by the foetus in utero during pregnancy; with special reference to achondroplasia

(chondrodystrophia foetalis). D. B. HART. *Edinb. M. J.*, 1913, x, 496.

The origin of the syncytial lacunæ in human ova. HINSELMANN. *Deutsche Gesellsch. f. Gynäk.*, Halle, 1913, May. [454]

Cervical decidua. F. W. LYNCH. *Surg., Gynec. & Obst.* 1913, xvi, 694.

Urine analysis in midwifery. B. C. DONNARUMMA. *Gin. minore*, 1913, vi, 25.

Problems of obstetrical treatment. W. W. CHIPMAN. *J. Maine M. Ass.*, 1913, iii, 1356.

Remarks on Rotter's method of curing contracted

pelvis. E. GERSTENBERG. *Zentralbl. f. Gynäk.*, 1913, xxxvii, 409. [455]

Concerning hebosteotomy. L. A. KRIWSKY. *Monatschr. f. Geburtsh. u. Gynäk.*, 1913, xxxvii, 435. [455]

An obstetrical instrument. ROBT. SANITER. *München. med. Wchnschr.*, 1913, lx, 1437.

Investigations in regard to the so-called glande endocrine myometriale." FRAENKEL. *Arch. f. Gynäk.*, 1913, xcix, 225. [455]

Statistics of a Chinese policlinic. VORTISCH-VAN VLOTEN. *Arch. f. Schiffs- u. Tropen-Hyg.*, 1913, xvii, 253. [455]

GENITO-URINARY SURGERY

Kidney and Ureter

Recent studies of the adrenal glands. FRANZ LUCKSCH. *Prag. med. Wchnschr.*, 1913, xxxvii, 365.

Birefractive lipid of the suprarenals. WELTMANN. *Beitr. z. path. Anat. u. z. allg. Path.*, Jena, 1913, lvi, No. 2.

Extirpation of the suprarenal capsules in a mouse in parabiosis. MORPURGO. *Gior. d. r. Accad. di med. di Torino*, 1913, lxxvi, Nos. 1-2.

Röntgenological diagnosis in disease of the kidneys. A. BURCHARD. *Fortschr. a. d. Geb. d. Röntgenstr.*, 1913, xx, 244.

Bilateral lithiasis. OLIVER C. SMITH. *N. Y. M. J.*, 1913, xcvi, 1282. [456]

Notes on two cases of urinary calculus. C. A. MOORE. *Bristol Med.-Chir. J.*, 1913, xxxi, 120.

Radiography in the diagnosis of nephrolithiasis. KLEINBERGER. *Berl. klin. Wchnschr.*, 1913, l, No. 22.

On the differential diagnosis of appendicitis and nephrolithiasis. KROTOSZYNER. *Calif. St. Med. J.*, 1913, xi, 287.

A case of pseudo-calculus in the X-ray picture. PONZIO. *Gior. d. r. Accad. di med. di Torino*, 1913, lxxvi, Nos. 1-2.

Calculus of the renal pelvis; pyelotomy; recovery. BERNASCONI. *Bull. méd. de l'Algérie, Alger*, 1913, xxiv, No. 10.

Three cases of large renal calculi which had remained absolutely latent. PILLET. *J. d'urolog.*, Par., 1913, iii, No. 6.

Biliary calculi causing errors in renal radiography. ARCELIN. *Lyon méd.*, 1913, cxx, 1129. [456]

Experiments on the influence of an injured kidney on the kidney of the other side. K. ISOBE. *Mitt. a. d. Grenzgeb. d. Med. u. Chir.*, 1913, xxvi, 1. [456]

What should be the diagnosis of the contusions of the kidneys? TOUSSAINT. *J. d. praticiens*, Par., 1913, xxvii, No. 25.

Floating kidney in polycystic degeneration. CARLO. *Clin. chir.*, Milano, 1913, xxi, No. 5.

INTERNATIONAL ABSTRACT OF SURGERY

NOVEMBER, 1913.

ABSTRACTS OF CURRENT LITERATURE

GENERAL SURGERY

SURGICAL TECHNIQUE

ANÆSTHETICS

Kruskal: Intratracheal Ether Anæsthesia. *Surg., Gynec. & Obst.*, 1913, xvii, 117.

By Surg., Gynec. & Obst.

Kruskal reports 84 cases of intratracheal ether anæsthesia with the Elsberg apparatus. While his experience in thoracic surgery is limited only to cases of empyema and lung abscess, he finds this method of decided advantage in operations where the anæsthetist is in the way or the position of the patient makes the administration of an anæsthetic awkward. In cases of obstruction to the upper air passages this method eliminates all the dangers of the ordinary methods of anæsthetization.

In the aged and feeble the relief of respiratory effort removes the strain on the cardiovascular system and thereby minimizes post-operative shock. The return current of air prevents the inhalation of blood and mucus and eliminates a decided factor in the production of aspiration pneumonia.

The technique of administration is that advocated by Elsberg; he finds that the introduction of the catheter has been extremely simple with the use of the Jackson laryngoscope. The only difficulty experienced with the method is the fact that in a number of his early cases the anæsthesia had been insufficient and it was found impossible to cause complete abdominal relaxation to permit thorough exploration.

McMechan: Oxygen and Anæsthesia. *Internat. J. Surg.*, 1913, xxvi, 205.

By Surg., Gynec. & Obst.

McMechan quotes the experiments of Gatch in over-ventilating the lungs post-operatively with oxygen in the presence of carbon dioxide retention, and after an exhaustive personal experience with the method at the close of drop-ether anæsthesias, states that not only is it successful in eliminating

the remnants of the anæsthetic from the alveoli of the lungs, the circulation and the cellular tissues, but also that after an interval of such rebreathing, depending in length upon the time of previous etherization, patients awaken in rational possession of their faculties, have no nausea or vomiting, unless the necessary manipulative trauma of the operative procedure has evoked such reflexes, and seldom encounter such dreaded post-anæsthetic sequelæ as acetonuria, uremia, acute dilatation of the stomach, pseudo-obstruction of the bowels or pneumonia.

Bunge: Experiences with Anæstheticum Novum (Erfahrungen mit Anæstheticum novum). *Deutsche zahnärztl. Wchnschr.*, 1913, xvi, 297.

By Zentralbl. f. d. ges. Chir. u. i. Grenzgeb.

Anæstheticum novum consists, pro ccm., of novocain, 0.02, suprarenin, 0.05, extract. cort. Hamamel, 0.01, Natr. chlorat., 0.0064, sterilized in the autoclave. It is prepared in Dr. Glärsner's apothecary shop in Kassel. In 900 cases of dental operations in which this anæsthetic was used the author observed complete anæsthesia without unpleasant accessory effects, such as swelling of the soft parts, after-pains, or late hæmorrhages. The time interval was one-half minute for the upper jaw, one to ten minutes for the lower jaw, and three to fifteen minutes to produce anæsthesia due to loss of nerve conduction with injections of one half to two ccm. HERDA.

Schütz: Magnesium Narcosis (Zur Kenntnis der Magnesiumnarkose). *Wien. klin. Wchnschr.*, 1913, xxvi, 745.

By Zentralbl. f. d. ges. Chir. u. i. Grenzgeb.

In animals subcutaneous injections of a magnesium salt produce narcosis which can be stopped by injections of calcium compounds. Kocher utilized these properties in the therapy of tetanus. Schütz's

investigations have led him to the following preliminary results: After a single injection of a non-lethal, sleep-producing dose of $MgSO_4$ or $MgCl_2$, magnesium could be demonstrated in the blood, liver, and in traces also in the brain. Repeated injections lead to a deposit in the brain which may be inhibited by calcium chloride. These relations remained uncertain in muscle. Sodium oxalate occasionally increases the sensitiveness to

magnesium. Experimentally the inhibitory action of calcium could be prevented by sodium oxalate. The experiments indicate that either small changes in the ionic cell content are enough for narcosis or the magnesium invades the cells only secondarily and is primary at the cell membrane. As yet nothing can be said as to the point of attack of magnesium. Some consider it central; others assume an action similar to curare. WEICHERT.

SURGERY OF THE HEAD AND NECK

HEAD

Spude, H.: Successful Treatment of Cancer of the Face by Simple Puncture with Ferrous Oxide (Erfolgreiche Behandlung von Gesichtskrebsen durch einfache Einstichlung von Eisenoxyduloxyd). *Ztschr. f. Krebsforsch.*, 1913, xiii, 139.
By Zentralbl. f. d. ges. Chir. u. i. Grenzgeb.

The author has succeeded in healing over ex-cochleated carcinomas of the face quite rapidly by injecting ferrous oxide into the base of the ulcer. The efficacy of this regional treatment was enhanced in one case of extensive carcinoma by the subcutaneous administration of atoxyl and arsenic. Spude expresses the hope that he may be able to heal inoperable or recurring carcinomas of the internal organs by the same principle, though with a somewhat altered technique as regards its application.

GENEWEIN.

Murphy, J. B.: Ankylosis of the Jaw — Interposition of Flaps from Mucosa of Mouth. *Surgical Clinics of John B. Murphy*, 1913, ii, No. 3.
By Surg., Gynec. & Obst.

The patient, a man of 28, in July, 1909, had an abscess about a molar tooth in the right upper jaw. He was not treated for 3 weeks; at the end of that time the abscess was opened from within the mouth and cauterized. A week later an external incision was made. Only a little pus was evacuated. Shortly after the operation ankylosis began to develop and steadily grew worse. A year after the onset an operation was performed to relieve ankylosis, but was unsuccessful.

There are three types of ankylosis in the jaw; i. e., fibrous ankylosis, bony ankylosis and ankylosis arising from cicatrices outside the joint. The case described above proved to be of the extreme articular fibrous type. A solid band extended on the outer side from the upper to the lower jaw and clear back to the ramus. The anæsthetic was given through the nose, and the mouth was held open with a gag. The adhesions were separated very carefully with a scalpel and scissors, the finger being used as a guide. After much work, the mouth was opened wide. The tongue was drawn then to the opposite side and two flaps were interposed, one from the floor of the mouth and the other from hard palate. Both

were tongue-shaped, the lower 2 inches long and $\frac{1}{2}$ inch wide, the upper, 2 inches long and 1 inch wide. The base of the upper flap was directed toward the alveolar process, and that of the lower, toward the tongue. Both were swung out to cover the raw surface left by dividing the adhesions. The tips of the flaps were sutured to the inner margin of the gum and the cheek. All suturing was done with fine catgut, and no tension was exerted on the flaps.

L. J. MITCHELL.

Park, R.: Conclusions Drawn from a Quarter Century's Work in Brain Surgery. *N. Y. St. J. Med.*, 1913, xiii, 303.
By Surg., Gynec. & Obst.

The paper opens with a short history of the advance made in brain surgery. The author then takes up the various brain lesions and discusses the question as to whether there has been any advance in the treatment in the last twenty-five years. He states that the expectations have been much greater than the realizations. In the treatment of injuries of the cranium the results are gratifying. As far as the actual structure of the brain permits, the resources to-day leave little to be desired. He says further:—"In the treatment of *hæmorrhage*, spontaneous or traumatic, great advance has been made; in the treatment of *hydrocephalus* not so much; here the condition itself is almost insuperable. In the matter of technique a great advance has been made. We now have very nearly perfect contrivances for any manipulation which the construction of the parts may justify. Never until recently, for instance, have instruments been devised by which it appears impossible to injure the brain while perforating the skull. These, Hudson, of Atlanta, has finally succeeded in producing, and with them, as with forceps also of his device, the matter of raising osteoplastic bone flaps of almost any size or shape has been greatly simplified. With such instruments as these it is therefore a comparatively simple matter to carry out operations intended for decompression, which shall, in 'all probability, prove most effective in the relief of symptoms of brain pressure produced by lesions not permitting radical attack.

"The surgery of the *hypophysis*, and one or two other of the recent methods of attack for particular indications, are yet so recent as not to come within the scope of this paper. They give every indica-

tion of brilliancy and promise, but are still on trial."

The author comes to the following conclusions:

The surgery of *brain tumors* in general is still a disappointment, so far as radical measures are concerned. In all but a very small percentage of cases a decompression operation will better serve the purpose. With regard to *abscess*, precisely the same statement cannot be made, because here, unless the focus is found, practically nothing is accomplished; but the localization of this focus is but slightly more accurate than formerly. In the matter of the *lepties* and the *psychoses* the operative measures are ample, and the technique sufficient save in one respect, the prevention of fresh adhesions. Far more accurate notions regarding etiology are needed, and better discrimination between surgical and non-surgical cases.

Intracranial surgery has then made a great advance, but the hopes raised in 1888 have not yet been fully realized in 1913. EDWARD L. CORNELL.

Nowikoff, W. N.: A New Way of Attacking the Hypophysis (Ein neuer Weg für Eingriffe an der Hypophyse). *Zentralbl. f. Chir.*, 1913, xl, 1000.

By *Zentralbl. f. d. ges. Chir. u. i. Grenzgeb.*

Nowikoff has modified the Linenkoff method of temporary resection of the superior maxilla and the nose and worked out a method which renders a broad access to the hypophysis, to the under surface of the pons, and to the elongated medulla. The procedure is as follows: An incision in the skin is made over the zygomatic arch, along the lower border of the orbit, over the root of the nose, and down along the opposite border of the nose around the nostril to the midline. The upper lip is divided in the median line. The periosteum is separated from the lower orbital wall to the inferior orbital fissure. The bone is separated from the tear sac and the zygomatic bone with its two frontal processes is then exposed. The zygomatic arch and the frontal processes are divided. The bony framework of the root of the nose is sawed through after the introduction of a Gigli saw. A longitudinal incision is made in the mucous membrane of the hard palate of the opposite side and the bone and the apertura pyramidalis are divided with a chisel.

The nasal septum is divided from the opening at the root of the nose. The maxillary bone and the nose can then be liberated from their bed, and this allows a broad access to the base of the brain. The sphenoidal sinus comes clearly into view and its anterior wall is chiseled away. By means of a conchotome, the other wall of the sphenoidal sinus is then removed in toto. This exposes the upper wall of the sphenoidal sinus which at the same time is the floor of the sella turcica. This is carefully opened for a short distance. When the operator has made sure that the cavernous sinus is not immediately above it, the opening is enlarged sufficiently to expose the hypophysis. Without much difficulty the body of the sphenoid bone and of the basal part

of the occipital bone can be removed to expose the lower half of the pons and the elongated medulla. After the superior maxilla and the nose have been replaced, the base of the brain can be drained to the outside. The author has performed this operation so far only on the cadaver. WOLFSOHN.

NECK

Von Mutschenbacher, T.: The Treatment of Scrofulous Lymphatic Glands of the Neck (Wie behandelt man skrofulöse Halslymphdrüsen)? *Berl. Klin.*, 1913, xxv, 1.

By *Zentralbl. f. d. ges. Chir. u. i. Grenzgeb.*

The author's experience includes about 1500 cases of lymphomata colli which he observed at the Réceis clinic in Budapest. Of these, 121, or 9 per cent, were operated upon. The others were treated conservatively. There are three types of this disease, each of which calls for a particular method of treatment. Type I is characterized by short, hard, non-caseous lymph glands. Of this kind were 74.5 per cent of the cases. Nutritious diet, iron and arsenic preparations, climatic treatment at the seashore or in the mountains, sunlight and Röntgen-ray treatment give quick and good results. If the glands soften they should be punctured. External applications (iodine and mercury ointments) and poultices should not be used. Type II is characterized by closed and suppurating glands. Of this form were 17.2 per cent of the cases of this disease. Since, after free incision, healing takes place very slowly and leads to deforming scars, treatment ought to be restricted to puncture followed by injections (the author recommends iodoform in glycerin). Only in those cases that are complicated by other manifestations of tuberculosis (lupus, laryngeal, or bone tuberculosis) should an open incision be made. In Type III the glands are suppurated and form fistulous tracts through the skin. They should not be excised, curetted, nor cauterized. Sunlight and general treatment give very good results. The application of green soap is recommended.

In all cases of glandular involvement of the neck Waldeyer's lymphatic ring in the pharynx should receive attention and appropriate treatment.

POSNER.

Mansfeld, G.: The Effect of Thyroid Gland upon Blood Formation; a Contribution to the Physiology of the Thyroid Gland. Number 2 (Blutbildung und Schilddrüse. Beiträge zur Physiologie der Schilddrüse. Mitteilg. 2.). *Arch. f. d. ges. Physiol.*, 1913, clii, 23.

By *Zentralbl. f. d. ges. Chir. u. i. Grenzgeb.*

Mansfeld attempted to discover by means of experiments on rabbits whether the effect of a lack of oxygen on the formation of blood is to be attributed to increase in the activity of the thyroid gland. In normal animals he noted the well-known effect of high altitude upon the number of erythrocytes, but in animals whose thyroid glands had been

removed the increase did not take place. The regeneration of the blood after phenylhydrazin anæmia was much less proportionally in animals whose thyroid glands had been removed than in normal animals, this difference being most marked at high altitudes (5 per cent in abnormal animals as compared with 63.2 per cent in normal animals).

The hæmoglobin of the blood increased at a high altitude in normal animals but decreased in animals without a thyroid. The regeneration of the hæmoglobin he found was not parallel to that of the erythrocytes but it took place at a high altitude even in animals without a thyroid. Carbot's serum from animals without a thyroid was as effective as that from animals that were normal. The use of this serum caused a decrease rather than an increase in the red blood cells in animals without a thyroid. Thyroid extract several days after Mansfeld had ceased administering it caused a marked increase in the red blood cells. From two metabolism experiments carried on after the discontinuance of the administration of the thyroid extract and in which there was noted an increase in the red blood cells but no increase in the nitrogen excretion, the author concludes that thyroid material does not directly influence either the nitrogen output or the nitrogen retention. Six other metabolism experiments showed that the decomposition of albumin caused by the lack of sufficient oxygen, which the author attributed to increased thyroid activity, did not recur when the supply of oxygen was further limited. Mansfeld concludes from this fact that when the deficit of oxygen is slight it causes a stimulation of the thyroid activity, but when it is more pronounced and of longer duration it inhibits the thyroid activity. This conclusion agrees with those of Reich and Blauel.

Mansfeld's conclusions are as follows: High-altitude anæmia and Carnot's serum cause a new formation of red blood cells (as does the administration of thyroid). This depends upon the stimulation of the thyroid and an increased secretion. New formation of erythrocytes, which depends upon the stimulation of the bone marrow by the thyroid secretion, therefore, takes place only when the thyroid is active. The albumin that is retained after the discontinuance of the administration of thyroid is used in the formation of the new red cells. An increase in erythrocytes does not take place during the administration of thyroid or during a period of hypersecretion, since at this time there is an albumin deficit. All of Mansfeld's findings need clinical confirmation. KOCHER.

Solaro, G.: Osteosarcoma of the Thyroid Gland (Ostéosarcome de la glande thyroïde). *Clin. chir.*, 1913, xxi, 1101. By Journal de Chirurgie.

This rare observation is especially interesting from the point of view of pathological anatomy.

As in most of the cases so far reported, the osteosarcoma described by Solaro developed in a gland that was already diseased (goiter). It affected the

left lobe and it was possible to readily enucleate it like a goiter. An infiltration, however, recurred with great rapidity.

Histologically this growth was an osteosarcoma similar to those that occur in bones. The sarcomatous tissue is the youngest and most active part of the tumor and by successive modifications it changes to osteoid, bony, and cartilaginous tissue. In the recurring tumor there were found sarcoma cells almost exclusively with but little bone and no cartilage.

The osteosarcoma may have had its origin in an osteogenic rest in the thyroid derived from the bronchial apparatus, but the author prefers to consider it a direct metaplasia of the connective tissue.

PIERRE FREDET.

Gatti, G.: Echinococcus Cyst of the Thyroid (Kyste à échinocoques de la thyroïde). *Clin. chir.*, 1913, xxi, 713. By Journal de Chirurgie.

A hydatid cyst of the right lobe of the thyroid of 20 months' duration was observed in a child of five. An attempt was made to enucleate the cyst proper and its capsule, but it ruptured and thyroid tissue had to be removed.

The author makes a critical study of the literature of the subject and, as treatment, advises in order of preference, enucleation, partial resection of the thyroid or marsupialization.

Attention is called to the fact that Gatti uses the term "enucleation" in a sense different from that in which it has been used since the work of Delbet. Gatti speaks of enucleating the extraparasitic sac formed to wall off the parasite. This, as in hydatid cysts of the liver, would be radically impossible. One may agree with Gatti, however, if the latter proposes enucleating the hydatid cyst proper, which, in the case cited, could have been easily accomplished as there were no adhesions between the cyst wall proper and the thyroid capsule surrounding it.

PIERRE FREDET.

Jamin, F.: The Combination of Thyreoses and Nephroses (Über die Kombination von Thyreosen mit Nephrosen). *Deutsche Ztschr. f. Nervenheilk.*, 1913, xlvii-xlviii, 255 (Festschr. von Strümpel).

By Zentralbl. f. d. ges. Chir. u. i. Grenzgeb.

The author describes cases in which a more or less definite picture of thyreosis was accompanied by definite disturbances in the kidney. That this was not merely a coincidence was proven by the effect that the one exerted upon the other. The mildest cases were represented by the so-called orthostatic albuminuria, especially that occurring in young girls. Although this condition is frequently designated as chlorosis, the accompanying rapid enlargement of the thyroid gland and the blood picture proves that it belongs to the group of thyroid disturbances. Besides the thyroid, also other organs of internal secretion may be involved and may produce symptoms difficult to interpret.

In many cases disturbances of development

are soon noted. In fully developed hyperthyroidism, disturbances in the kidney belong to the clinical picture. These cannot be attributed to the cardiac injury alone; they must have some specific cause. They may come and go with the change in the severity of the disease. In one case that is described in detail the thyreotoxic patient had a very unstable nervous system and a prolonged increase in the blood pressure. He suffered also a continued disturbance in the kidneys that was manifested by albuminuria and polyuria. Two other cases showed similar findings. Common to both was the thyreosis, together with the symptoms of a status thymolympathicus, hypertrophy of the left ventricle, prolonged increase in the blood pressure, and kidney disturbance. The female sex of mature age seems especially predisposed. The increased blood pressure may be borne for years.

The pathogenesis is not definitely known. It is highly probably that a disturbance of internal secretion is the primary factor. Accidental injury to the kidneys by infection or toxic agents cannot, of course, be absolutely excluded, but the kidney disturbance will be much more severe if the sympathetic and autonomous nervous system has become hypersensitive by reason of the thyreosis. The high blood pressure in these cases appears to be due to an increased peripheral resistance which is of a functional rather than a morphological character. Atherosclerosis is not a factor; the vascular system is still capable of adapting itself and it is for this reason that the increased blood pressure can be well borne. As to whether an internal secretion of the kidney enters into consideration cannot be stated at this time; such a secretion should manifest itself by a stimulating action upon the suprarenals. In the observation that thyreotoxic symptoms may occur in old people with contracted kidneys and hypertension, a parallel is found to the cases described.

The therapy demands much care; these patients do not stand operation as well as others. Ligation of the vessels may be attempted first. Digitalis is not of use.

LEBENHOFFER.

Mayo, C. H: Surgery of the Thyroid; Observations on Five Thousand Operations. *J. Am. M. Ass.*, 1913, lxi, 10.

By Surg., Gynec. & Obst.

Sporadic, endemic and epidemic goiters are found in all parts of the world, among all people and most animals. As yet we have no knowledge of a specific infecting agent which can be regarded as the causative factor in the production of goiter. The work of the Goiter Commissions and the reports of those observers who have made a study of the etiology of goiter make it quite apparent that, whatever the agent, it seems to be more readily conveyed by water than by any other medium, although water is probably not the sole carrier. The more recent progress in the non-surgical treatment of goiter seems to indicate the use of thymol, salol and iodine as intestinal antiseptics. Thyroid gland has an uncertain potency, yet apparently produces favor-

able results in the early treatment of simple goiters. In exophthalmic goiter temporary improvement may be obtained by the use of the X-ray. The cytolytic serums for specific action on the thyroid have not borne out in results the expectations of the medical profession. The thymus gland and the thyroid are undoubtedly intimately associated in the growth and development of early life. The thyroid may be of great size in advanced middle age, compressing the trachea at, or just above, the bifurcation. Such complications are more common and more grave in goiters of the hyperplastic type. Large right-sided goiters frequently produce paresis of the left recurrent nerve, and it is therefore advisable to make a laryngoscopic examination before doing a thyroidectomy. Extensive exposure of the nerve is advisable only in an operator's early experience, or in operating on nodular thyroids which extend beneath the trachea and have displaced the nerve. The scar tissue which results from the traumatism of a free exposure may lead to secondary paresis. In performing thyroidectomy the best exposure to be obtained is through a transverse incision low in the neck, the skin and platysma turned together both ways from the incision. Should further exposure be necessary the sternohyoid can be sectioned high in the exposed area. In simple goiter it is best to extirpate a greatly enlarged lobe. If both lobes are symmetrically enlarged, division of the isthmus with double resection of glands is indicated for the best cosmetic results. Midline, encapsulated adenomas should be enucleated with division of the isthmus. Lateral encapsulated adenomas may be enucleated or the whole lobe extirpated. If symptoms of hyperthyroidism are present extirpation is indicated. Excluding malignancy the mortality in operating on goiters is very low (1-3) and varies but little in the so-called simple goiters, in which class are included occasional complications, and the cases of so-called exophthalmic goiter with hyperplastic glands. In the 5000 operations on the thyroid in the clinic at St. Mary's Hospital during the 25 years ending May 14, 1913, there were 2396 operations for simple goiters which included 11 transplantations in cretins, 59 operations for malignancy (52 carc., 7 sarc.), and one for syphilitic thyroid. There were 2295 operations for exophthalmic goiter and 309 early operations which were not classified.

In discussion, CRILE confirmed Mayo's conclusions by his own experience, having operated over eight hundred cases of goiter of all types and varieties. He has seen a few cases in which cancer of the thyroid, not suspected before operation, but found by the pathologist, was cured. The safety of the operation for colloid goiter is so great at the present time that, if the patient demands operation, one is justified in removing the gland for cosmetic reasons. The care Mayo suggested in the preservation of the voice is excellent. Crile has found that one may take out the entire lobe, carrying the dissection right to the edge of the capsule, using small hæmostats, and keeping a bloodless field so that one can see

the lymph vessels as they run out of the gland from beginning to end of the operation. In this way it would be impossible to remove either a parathyroid or to injure the recurrent laryngeal nerve.

Passing to another subject, he wishes that a commission might be appointed for the purpose of investigating the adolescent period of children living in goitrous districts. Crile believes that the syrup of ferrous iodid in five minim doses, three times daily, for periods of a month during every year, will control nearly all cases of simple hypertrophy. One of the factors in the production of adolescent goiter lies in the geological change in the constituents of the earth where iron is not found as it once was. He finds that clinically one can make a very accurate prediction of the pathological condition in the gland. There is no more doubt in his mind as to the benefits of operation for exophthalmic goiter than of opening the abscess. Patients confirm that view, and the clinics have grown not through references by physicians, but through references by patients.

He believes that there is a general feeling not only among surgeons, but also among patients, that exophthalmic goiter is a disease that should not be allowed to go on until the stage of degeneration is reached. Crile believes that the late results of the disease are largely under control. One can operate now and control the hyperthyroidism by the principle of anoci-association, and not have a single change for the worse at the end of the operation, no matter how severe the case, how large the gland, or how rapid the pulse rate.

Porter: Injection of Boiling Water in the Treatment of Hyperthyroidism. *J. Am. M. Ass.*, 1913, lxi, 88. By Surg., Gynec. & Obst.

Porter's experience in the treatment of angiomas by the injection of boiling water, as first advised by Wyeth, led him to use this method on three classes of cases:

1. Patients too sick to be safe surgical risks, and those having dividing or substernal goiter the removal of which would be extra-hazardous.
2. Patients presenting mild symptoms.
3. Patients who refuse, major surgical procedures.

He has treated over twenty cases, representing in all more than one hundred injections. From one to three injections were given at each treatment, of from 40 to 230 minims. The injection of boiling water into the thyroid gland is a safe procedure. The immediate effect of the injection is destruction of thyroid tissue and colloid. Further destruction of thyroid cells results from the formation of fibrous tissue consequent to the injection. L. G. DWAN.

Dufour, P.: Two Cases of Hemithyroidectomy for True Exophthalmic Goiter of Tubercular Origin (Deux cas d'hémithyroidectomie pour goitre exophthalmique vrai d'origine tuberculeuse). *Lyon med.*, 1913, cxx, No. 14. By Journal de Chirurgie.

Dufour reports two cases in which Leriche performed a partial thyroidectomy for exophthalmic

goiter. The first was that of a patient 41 years old who had had an enlarged left lobe for two years with palpitation, tremor, diarrhoea, and tachycardia but only slight exophthalmus. Fifteen days after a partial thyroidectomy had been performed only the tachycardia remained and this was improved. The second case was that of a patient 33 years old who had had a goiter since she was 19. Symptoms of Basedow's disease appeared in September, 1910. In May, 1912, she had an acute Basedow's disease and after symptomatic treatment to improve her condition she was operated upon in August, 1912, under local anæsthesia. The tachycardia and nervousness have disappeared but after five months the patient still has a slight tremor although she is otherwise in excellent health. Four other partial thyroidectomies performed by Leriche and Poncet have had equally good results. Two of the patients have remained in good health for four years. The finding of tuberculous lesions in two cases tends to substantiate the statements of Poncet and Leriche that certain exophthalmic goiters are of tubercular origin. J. DUMONT.

Eppinger, H.: Basedow's Disease (Die Basedowsche Krankheit). *Handb. d. Neurol.*, 1913, iv, 1. By Zentralbl. f. d. ges. Chir. u. i. Grenzgeb.

The article is a discussion of Basedow's disease on the basis of our present knowledge and the author's own studies of the condition. After enumerating in detail the well-known symptoms and weighing their relative importance, the author enlarges on his own theory. Eppinger believes that the theory of Klos and his co-workers, that the condition is a dysthyreosis, is incorrect. The investigations of A. Kocher, as well as other considerations, force us to retain the theory that it is a hyperthyroidism. Special reference is made to Kocher's nuclear lymphatic centers in goiter tissue. Persistent thymus and Basedow's disease are not necessarily associated.

The paragraph on differential diagnosis is comprehensive. Typical cases are easily recognized. Atypical forms presenting only one or two symptoms can be classified as sympatheticotonic or vagotonic.

Other subjects discussed are: The relation of the thymus to Basedow's disease, struma basdificata, the various cardiac findings in goiter, glycosuria in Basedow's disease, Kocher's "Jodbasedow," and Basedow's disease in children. The numerous complications of the disease can best be studied from the original article. Considering the brilliant operative results of Kocher, with 76 per cent cures, the author recommends the surgical treatment decidedly. However, removal of the thyroid is not without risk. Even Kocher reports a mortality between 3.4 and 6.7 per cent. Recurrences are not rare. A vascular appearance of the goiter constitutes an indication for operative therapy. X-ray treatment should not be used. Although the best results are obtained by operation, internal therapy is by no means valueless. A dietetic-hygienic régime is essential. Of medicinal remedies the au-

thor has successfully used atropin sulphate in pills (0.00025) two to three times daily, especially in cases with severe diarrhoea. Injections of adrenalin are suggested; 20 to 30 drops in 250 gm. of warm water should be allowed to flow in slowly for 5 to 10 minutes. Calcium carbonate is also recommended. If there is no improvement at the end of from one

to three months under medical care, operation is indicated. The author supports Mayo's suggestion to give atropine (belladonna) before a general anæsthetic is administered, for he believes that the so-called "thymus-death" is nothing more nor less than a result of shock which seems to affect principally the vagus. EUGEN SCHULTZE.

SURGERY OF THE CHEST

CHEST WALL AND BREAST

Evans: Cancer of the Breast. *Practitioner*, Lond., 1913, xci, 7. By Surg., Gynec. & Obst.

The author believes the mode of local extension of carcinoma is best described by the term "infiltration process" since it travels by way of the lymph channels, and does not spread like a wave from a central focus, as would be implied by the term "permeation." Attention is directed to the clinical importance of the inconstant, deep, paramammary lymphatic gland situated at the outer border of the breast. When secondarily invaded it may lead to the belief that two primary foci exist. Other diseases may involve it and thus lead to confusion in diagnosis. Retraction of the nipple or tissue of the breast is not in itself an indication of malignancy, but if gentle fondling of the breast fails to cause a contractile response of the nipple, we have a sign of some value.

The teaching that "chronic interstitial mastitis may become malignant" is considered unsound by the author for the reason that fibrous tissue cannot revert to a proliferating cellular growth. He is using lactagol as an aid in differentiating malignant growths from chronic interstitial mastitis with some success.

Interesting papillary growths from the ducts—either intracystic or protruding—are to be considered in the differential diagnosis of carcinoma. Also in every case, the involvement of supraclavicular lymph glands, secondary to either carcinoma of the breast or to carcinoma elsewhere in the body, should be carefully sought for.

The author believes that early, thorough, radical removal, which includes the pectoralis major muscle as well, is the only course to pursue. F. B. RILEY.

Ritter: The Prognosis of Cystadenoma of the Breasts (Zur Prognose des Cystadenoma mammæ). *Monatschr. f. Geburtsh. u. Gynäk.*, 1913, xxxvii, 679. By Zentralbl. f. d. ges. Gynäk. u. Geburtsh. s. d. Grenzgeb.

Following the removal of both breasts on account of a cystadenoma, a carcinoma developed in the axilla, which is now recurring. At the time of the removal of the cystadenoma, microscopic examination revealed no indications of a carcinoma within it.

The author explains the extraordinary growth as follows: In seven cases operated upon for cystadenoma, he found lymph glands in the

axillary space which seemed to be still in a state of development and of a type that occurs only in cancer of the mammary gland. The presence of these growths in the cases described makes it seem probable that, though cystadenomata are generally benign, they nevertheless possess characteristics of malignant tumors which may cause the development of cancer after they have been removed. Ritter therefore advises the extirpation of the regional lymphatic glands in every case of cystadenoma of the breast. ZINSSER.

Gourdon: Bilateral Sterno-Clavicular Dislocation of Congenital Origin (Luxation sterno-claviculaire bilatérale, d'origine congénitale). *Rev. d'orthop.*, Par., 1913, iv, 304. By Journal de Chirurgie.

In this article Gourdon reports the case of a boy of 15 who was suffering from a slight dorsal kyphosis and bilateral sterno-clavicular dislocation. The dislocation was complete. Gourdon points out the difference between a luxation of this kind and the subluxations often noted in young girls. In the case reported it was possible by palpation to twist the entire internal end of the clavicle around. The movements of the sterno-clavicular articulations were much exaggerated and sluggish. The attention of the boy and his parents had never been drawn to the luxation of the articulations. Gourdon believes that although the dislocation was not noticed until late, it was a deformity of congenital origin and was due to the absence of interarticular fibro-cartilage. We believe, rather, that it was the result of an atrophy of the osseous extremities and a malformation of the articulations and the entire ligamentous connection.

The prognosis is bad, as the deformity has a tendency to become exaggerated and it is difficult to correct by any method (arthrodesis, resection of the clavicle, bandages, pressure, or casts, etc.).

Gourdon recommends no therapeutic treatment for such cases. The projection of the clavicle is of little importance if, as in the case reported, the patient has the use of his limbs. ALBERT MOUCHET.

Schepelmann, E.: Thoracotomy and Hydrothorax (Thorakotomie und Hydrothorax). *Klin. therap. Wchnschr.*, 1913, xx, 681.

By Zentralbl. f. d. ges. Chir. u. i. Grenzgeb.

The author has conducted a series of experiments on animals to verify the conclusions of Teske as to

the effects of artificial hydrothorax. Single and double pneumothorax were produced in guinea pigs under the influence of morphine. Observations were then made of the frequency of respiration after removal of the pressure, and also after the injection of physiological salt solution and olive oil into the pleural cavities under normal pressure. With unilateral pneumothorax and normal pressure the type of respiration was favorably influenced to a slight degree by the injection of salt solution, and to a greater degree by the injection of oil. The good effects were more marked when the quantities of the fluids injected were large (several tablespoonfuls). When both pleural cavities were opened neither the salt solutions nor the oil had any effect upon the rate of respiration.

The explanation given by Schepelmann for these phenomena is as follows: In unilateral pneumothorax the weight and pressure of the injected fluid puts the mediastinum at rest and does away with the injurious mediastinal fluttering, so that the normal lung can breathe quietly. When both pleural cavities are opened mediastinal function is suspended and, as a result, the beneficial effects of injections of fluids have no chance to manifest themselves. The results of the author's experiments do not agree with the theories of Teske either with regard to the effects of artificial hydrothorax or to the explanations in general. Nevertheless, Schepelmann advises, beside the free opening of the thorax, the injection of warm physiological salt solution into the pleural cavities to prevent the harmful drying of the endothelial surfaces of the pleura, and to minimize the danger of infection. At the end of the operation a decided increase in pressure of the fluid washes out any germs that may have entered. Moreover, the salt solution remaining in the chest is more easily and quickly absorbed than the air in a pneumothorax.

DENK.

Schur, H., and Plaschkes, S.: The Indications for Artificial Pneumothorax in Pulmonary Tuberculosis (Zur Indikationsstellung der Pneumothoraxbehandlung bei Lungentuberkulose). *Wien. klin. Wchnschr.*, 1913, xxvi, 961.

By Zentralbl. f. d. ges. Chir. u. i. Grenzgeb.

The authors briefly report their experiences with the pneumothorax treatment in cases of pulmonary tuberculosis. The best results were obtained in severe cases that showed marked involvement of one side only. The general condition improved rapidly, the temperature fell, and the appetite increased. In general, the results obtained by the authors with insufflation of nitrogen were similar to those of other investigators: no actual cures were observed. An exudative pleurisy was frequently observed but it always disappeared later.

The authors conducted experiments on animals to determine the cause of the favorable influence of pneumothorax upon tubercular lungs. The results showed that the compressed lung can be infected artificially with tubercle bacilli introduced intrave-

nously or by inhalation quite as readily as the healthy lung, and that therefore the favorable influence of the treatment is due, not to the compression, but to the changes in the connective tissue of the lung that occur in the period of pneumothorax compression.

From these results, as well as from the clinical findings, the authors conclude that in mild cases without severe general symptoms no improvement can be expected from the insufflation of nitrogen. When the constitutional symptoms are severe, however, and are due principally to involvement of one lung, this treatment is of value, since in such cases, by reason of the compression of the lung and the resulting blocking of the blood and the lymphatic circulation, the absorption of toxins is made much more difficult. Advanced involvement of the other lung, cardiac defects, kidneys affections, and extensive pleural adhesions are contra-indications to the treatment.

Kaufmann, K.: The Technique of Artificial Pneumothorax (Zur Technik der künstlichen Pneumothorax). *Internat. Zentralbl. f. d. ges. Tuberkul. Forsch.*, 1913, vii, 320.

By Zentralbl. f. d. ges. Gynäk. u. Geburtsh. s. d. Grenzgeb.

Kaufmann gives Brauer's method of incision the preference over the method of puncture. The disadvantages of the former are the occurrence of tissue emphysema, which is seldom absent, and the formation of pulmo-cutaneous fistulae when the procedure is not successful. Kaufmann mentions two personal observations of these unfortunate complications. He has attempted to overcome the deficiencies of both methods. His procedure, which is practical and has obtained good results for the last three years in the sanitarium at Schönberg, is as follows:

The skin and also the underlying tissue are well infiltrated with the anæsthetizing fluid as far as the periosteum of the inner margin of the upper rib. A trocar, the lumen of which just fits a Salomon's cannula approximately 2.5 mm. in thickness, is then plunged in up to the infiltrated rib near its inner border. The stylette is withdrawn and the Salomon cannula is inserted up to a certain mark on the trochar, which is well fixed on the rib. The patient is then told to breathe deeply. At the same time under gentle but steady pressure the trochar with the cannula is inserted into the intercostal space. The blunt point of the cannula thereby insinuates itself between the bundles of intercostal muscles. The tense pleura is penetrated with one stroke, the cannula being held somewhat obliquely. The lateral opening of the cannula, the position of which is indicated on the mark above mentioned, should be turned toward the pleural opening either above or below. A soft sound is used to determine whether the free cavity has been reached. Oxygen should always be introduced first. For this purpose a small modification of Brauer's nitrogen apparatus is essential. The latter is described by means of a diagram.

SCHUMACHER.

Tuffier, T.: Final Result of an Intrathoracic Subpleural Graft in a Case of an Intrapulmonary Suppurative Cavity on the Right Side (Résultat éloigné d'une greffe intra-thoracique sous-pleurale dans un cas de cavité suppurée intrapulmonaire droite). *Bull. et mem. Soc. de chir. de Par.*, 1913, xxxix, 740.
By Journal de Chirurgie.

Tuffier reports the case of a patient who had a depression in the bony framework of the thorax which was due to a large intrapulmonary cavity caused by gangrene. He remedied the depression by grafting into the pleural cavity a large lipoma that had been preserved on ice. At the present time, two years later, the patient is in the best of health; the thorax is symmetrical, the cicatrix elastic, white, and without adhesions. There is no purulent expectoration and on auscultation there are no abnormal sounds. The patient works without fatigue or pain.

TRACHEA AND LUNGS

Derjushinsky, S. E.: Artificial Breathing Continued Successfully for Fifteen Days (Erfolgreiche ununterbrochene künstliche Atmung im Laufe von 15 Tagen). *Verhandl. d. XII. Kong. russ. Chir.*, 1913, xii, 208.
By Zentralbl. f. d. ges. Chir. u. i. Grenzgeb.

Derjushinsky reports the only case that is known of artificial respiration continued successfully for fifteen days. The patient had pain in the neck and after six days was admitted to the hospital with paresis of all the extremities and facial paralysis on both sides, bilateral lagophthalmos, and paresis of the muscles of mastication. The pupil reflex was weak, and Babinsky's reflex was noted. The temperature and the condition of the internal organs were normal. At the end of two weeks there was complete paralysis of all extremities and a gradual cessation of respiration. Artificial respiration was then begun, and as spontaneous breathing did not return it was continued for fifteen days without interruption. For the first three days the pulse was rapid (100-150); from the fifth day on, it was normal. Spontaneous breathing began again after fifteen days, but stopped after five days. Artificial respiration was then carried on for three days longer, after which normal breathing was resumed. For the following three weeks the patient suffered from croupous pneumonia and intestinal paresis. Muscle atrophy was marked, but it disappeared completely, though slowly, after massage and electrical treatment. In four months the patient was discharged. She has been well ever since (eleven months).

HESSE.

Petrén, G.: Pulmonary Embolism as a Cause of Post-Operative Death (Studien über obturierende Lungenembolie als postoperative Todesursache). *Beitr. z. klin. Chir.*, 1913, lxxxiv, 606.
By Zentralbl. f. d. ges. Chir. u. i. Grenzgeb.

After a brief historical review, the author draws conclusions from a study of a vast amount of mate-

rial, some of which is his own. Death from pulmonary embolism occurs most frequently after laparotomy. One per cent of those operated upon for myoma, the same percentage of those who undergo laparotomy, and about two-tenths per cent of those operated upon for hernia die of this condition. Embolism is as frequent in one sex as in the other. It does not occur before the fifteenth year. It is common between the thirtieth and forty-fifth years, and most frequent in later years, regardless of the general condition of the patient. Vascular changes constitute an important etiological factor, but are by no means a constant finding.

Petrén next discusses the pathological anatomy, the localization, and the origin of embolism. Two-thirds of the fatalities occur between the fourth and fourteenth day after operation. In the case of patients in whom a positive diagnosis of thrombosis has been made, the danger is relatively less. Slight embolism may now and then precede the appearance of a thrombosis that is already present but has not yet been diagnosed. Mahler's symptom was not typical in any of the author's cases, and only exceptionally does it precede the appearance of an embolism that is fatal. It is quite improbable that embolism is caused by infection. On the other hand, cardiac weakness is often noticed in this condition. Also changes in the blood itself are, no doubt, contributory. The prophylaxis consists largely in preventing the formation of thrombus. This can be accomplished by early rising after operation, stimulation of the heart, respiratory exercises, and free evacuation of the bowels. When thrombosis has already developed, absolute rest is imperative. This must be required also in cases in which thrombosis is merely suspected. In conclusion the author discusses Trendelenburg's operation, and reports observations made in some of his own cases.

HEART AND VASCULAR SYSTEM

Jacob, O.: The Treatment of Tubercular Pericarditis by Pericardotomy Without Drainage (Traitement de la péricardite tuberculeuse par la péricardotomie sans drainage). *Bull. et mem. Soc. de chir. de Par.*, 1913, xxxix, 752.
By Journal de Chirurgie.

Jacob recalls that two years ago Rochard made a report to the Society in regard to a patient suffering from tubercular pericarditis with a great sero-hæmatic effusion. A pericardotomy without drainage was performed on this patient and the recovery was uneventful. Recently Jacob had the opportunity to perform again the same operation on a young soldier suffering from tubercular pericarditis. In this case also the patient was entirely cured.

There are, therefore, two reported cases of tubercular pericarditis that have been treated and cured by pericardotomy without drainage. These two cases seem to be important and to speak in favor of the treatment and technique that Jacob recommends.
J. DUMONT.

PHARYNX AND ŒSOPHAGUS

Guisez: Congenital Stenoses of the Œsophagus
(Les sténoses congénitales de l'œsophage). *Rev. méd.*, 1913, xxi, 262. By Journal de Chirurgie.

Congenital stenosis of the œsophagus is rare. Guisez observed only 4 cases of it in 1400 œsophagoscopies. In all of these cases it occurred in the region of the cardia and all of the patients were males from 10 to 30 years old. Each case had been previously diagnosed as a grave spasm of the œsophagus, but the spasm in reality was only secondary to organic stenosis.

Œsophagoscopy, which is the only means by which an exact diagnosis can be arrived at, has shown the same thing in each case. In the region of the cardia there is a sort of valve, more or less inflamed, modified by œsophageal peristalsis but preserving always its characteristic appearance and its easily recognizable sharp border. It is impossible to confound these congenital strictures with spasms of the œsophagus, in which the orifice is contracted and serrated, or with the inflammatory stenosis, in which there is no valve-like appearance, or with pressure stenosis, in which one of the walls of the œsophagus is pressed upon by a tumor and the lumen acquires the shape of a half-moon or a cross.

The prognosis is grave but depends essentially on the degree of stenosis and the treatment.

The treatment used was as follows:

1. The œsophagitis, which in all stenoses has a bad effect, was reduced. This reduction was accomplished by proper diet and by lavage of the œsophagus four times a day with an alkaline water with the aid of a Faucher tube.

2. The opening was dilated by olivary filiform bougies. A fine bougie was left in for several hours to make a passage.

3. It is nearly always necessary to actually cut the valve by œsophagotomy. In the author's last three cases he used circular electrolysis. In these instances the congenital stricture was accompanied by a slight cicatricial stenosis, and the

electrolysis gave results that could not have been obtained by œsophagotomy.

When enough of the valve is destroyed and the œsophagitis has been reduced by alkaline lavage and proper diet, there is but slight chance that the stenosis will recur. In all of the cases reported by Guisez alimentation rapidly became normal.

J. DUMONT.

Gesselewitsch: A Case of Œsophagitis Dessecans Following Poisoning by Acetic Acid (Ein Fall von Œsophagitis dessecans nach Essigsäurevergiftung). *Russk. Vrach*, 1913, xii, 771.

By Zentralbl. f. d. ges. Chir. u. i. Grenzgeb.

On the seventh day after taking acetic acid the patient ejected during an attack of vomiting the mucous, submucous, and part of the muscular, layers of the œsophagus. The structures retained their tubular form. Twenty cases of œsophagitis dessecans have been described in the literature, but no case following poisoning by acetic acid. The author believes that the occurrence of this condition would be noted more frequently if the vomitus were more carefully examined.

JOFFE.

Rotch, T. M.: Types of Occlusion of the Œsophagus in Early Life. *Am. J. Dis. Children*, 1913, vi, 1. By Surg., Gynec. & Obst.

This article is a report of three cases of occlusion of the œsophagus and is well illustrated by X-ray pictures. The first case was that of a boy 25 months old. The stricture was very tight. Gastrostomy was performed but the child died.

The second case was in a girl 10 years old. Orange pulp and a penny were found in the œsophagus. The œsophagus was very much dilated in the lower third; at a distance of 25 centimeters from the teeth there was a stricture one-half centimeter in diameter. The stricture was dilated with the œsophagoscope and the patient recovered.

The third case was that of a boy five and three-quarters years old and was really a spasm of the œsophagus.

CLIFFORD G. GRULEE.

SURGERY OF THE ABDOMEN

ABDOMINAL WALL AND PERITONEUM

Murphy, J. B.: Desmoid Tumor of Rectus Muscle. *Surgical Clinics of John B. Murphy*, 1913, ii, No. 3. By Surg., Gynec. & Obst.

A woman of 31 entered the hospital on account of a tumor in the right rectus above the umbilicus. The tumor was first noted some 6 weeks previous as a hard and fairly movable lump. Six months before, during the last 3 months of pregnancy, she suffered more or less constant pain in the region of the tumor. The pain grew worse but disappeared after parturition. There had been no change in the size or consistency of the tumor in the past 6 weeks, and

it was never tender. The patient's personal history was negative. Her father, mother and brother had died of carcinoma.

At operation the mass was found to be the size of the index finger and to involve $\frac{3}{4}$ of the diameter of the rectus. It sprang from the posterior layer of the sheath and grew out into the muscle. On operation it was separated from the peritoneum without opening the latter. The recovery was uneventful. The stitches were removed on 14th day, and the patient was discharged on the 22d day, being advised to wear an abdominal support for some time to give the tissues every opportunity to unite solidly.

L. J. MITCHELL.

Propping, K.: Rehn's Treatment of Peritonitis (Die Rehn'sche Behandlung der Peritonitis). *Deutsche med. Wchnschr.*, 1913, xxxix, 1096.

By Zentralbl. f. d. ges. Gynäk. u. Geburtsh. s. d. Grenzgeb.

For appendicitis peritonitis Propping recommends Rehn's treatment, which consists in a median incision, irrigation, eventration, and drainage of the pouch of Douglas. The article is mainly a criticism of a comparison made by Scheidtmann of the method of Rehn with the method of Rotter. The latter consists of irrigation of the abdominal cavity and mopping without drainage. Statistics of the last two years show an improvement in Rehn's mortality percentage. It is evident from the article, however, that good results were obtained with both methods. The mortality in Rehn's cases during the last year was eighteen per cent, as against twenty-four per cent for the year previous; that in Rotter's cases was 21.8 per cent.

ISELIN.

Blecher: Camphorated Oil in Peritonitis and Abscesses in the Pouch of Douglas (Campheröl bei Peritonitis und Douglasabscess). *München. med. Wchnschr.*, 1913, lx, 1261.

By Zentralbl. f. d. ges. Chir. u. i. Grenzgeb.

The author treated five cases of severe peritonitis, that occurred in fifty appendectomies, with one per cent of camphorated oil in amounts as large as 100 grams. The rapid improvement of the general condition and the ultimate recovery of all of the patients were attributed to the camphor treatment. In all of the cases an abscess was formed in the pouch of Douglas, which was also attributed to the camphor treatment. The oil checks the absorption, and a reflex inflammatory process that begins later causes an increase in the exudation. If there are no adhesions the exudate drains down easily between the oiled loops of bowel. The heavy exudate, covered by a fine coat of oil, is retained in the dependent parts, of which the pouch of Douglas is the lowest point. In two cases of acute paralysis of the stomach when the pelvis was elevated for a few days the formation of the abscess was delayed. Formerly the exudate from the pouch of Douglas was regarded as a favorable rather than an unfavorable symptom. To prevent such an exudate a glass or rubber drain, without gauze, should be inserted into the sac.

WORTMANN.

Härtel, F.: Tubercular Peritonitis (Die tuberkulöse Peritonitis). *Ergebn. d. Chir. u. Orthop.*, 1913, vi, 370.

By Zentralbl. f. d. ges. Chir. u. i. Grenzgeb.

The author, reviewing the more recent literature, refers to 191 articles on the subject, which contain the latest ideas on the etiology, frequency, and prognosis of this condition. The greater part of his article is devoted to a discussion as to whether the condition should be treated surgically or by the non-surgical or so-called "conservative" method.

The author's personal opinion is as follows: "It seems to me that the patients on whom laparotomy is performed have a decided immediate advantage

over those treated by other methods, but the longer they are kept under observation afterwards the plainer it becomes that they gradually lose this advantage, and the prognosis becomes about the same as that for the non-operated patients. In any case, after laparotomy, careful internal and restorative treatment should be persisted in for a long period, if possible in a sanatorium, a requirement that in most cases is difficult to meet." Härtel's article is more of a compilation than an expression of opinion.

ISELIN.

Stocker, S.: The Employment of Tincture of Iodine in Dry Peritoneal Tuberculosis (Die Anwendung der Jodtinktur bei der trockenen Peritoneal-tuberkulose). *Schweiz. Rundschau f. Med.*, 1913, xiii, 745.

By Zentralbl. f. d. ges. Chir. u. i. Grenzgeb.

Stocker, after employing the hot air treatment in cases of peritoneal tuberculosis with unsatisfactory results, endeavored, following the suggestion of Hofmann, to obtain a more powerful hyperæmia by applying tincture of iodine to the peritoneum.

Experiments with rabbits showed that when the bowels were painted with tincture of iodine no adhesions were to be found when the abdomen was opened later; instead the surfaces were quite smooth. In six other rabbits the abdominal cavity was opened and a freshly prepared emulsion of tubercle bacilli was painted on the peritoneal surface of the bowel. In three of these cases the application of the emulsion was followed with a coat of tincture of iodine before the abdomen was closed. In the others no iodine was used. At the end of four weeks no tuberculous changes were found in the animals in which the application of iodine had followed the introduction of the tubercle bacilli, and there were no adhesions. The other three animals showed distinct tuberculous changes. To these last three animals tincture of iodine was then applied as it had been applied formerly in the other three cases. At the end of two weeks there were observed definite retrogression of the changes.

From these experiments the author concludes that tincture of iodine exerts a direct curative influence upon tuberculous processes; that the danger of the formation of adhesions as the result of its use is much exaggerated; and that the application of the tincture of iodine may be safely employed in the case of the human being. Stocker reports the case histories of two patients that he treated with good results. Contrary to Hofmann's observations, ascites did not develop in these instances. WEHL.

Russanoff, A. G.: Tubercular Peritonitis and Its Operative Treatment (Zur Frage der Bauchfell-tuberkulose und ihrer operativen Behandlung). *Dissertation*, Moscow, 1913.

By Zentralbl. f. d. ges. Gynäk. u. Geburtsh. s. d. Grenzgeb.

The first part of this dissertation is devoted to a careful survey of the literature, the pathogenesis, the etiology, and the symptomatology of tuber-

culosis of the peritoneum. The second part is a discussion of the operative treatment and the indications for operative interference. The author has had twenty-four operative cases, nineteen women and five men. According to his statistics, tubercular peritonitis occurs most frequently in women.

The prognosis depends on the character of the tubercular process and the involvement of other organs. Operation must be performed early, while the general condition is still good. Adhesions should not be broken up except in cases of intestinal obstruction. Eight of the author's patients that were operated upon died, two at the end of the second week, one at the end of a month, one after three months, three after six months, and two after one year. The cause of death in all of these cases was progressive tuberculosis. In nine instances the patients remained well for periods varying from two to five years. The prognosis is best in fibrous tuberculosis, and worst when caseous granulations are formed.

Dietary treatment, according to the author, is next in importance to operative treatment. Puncture of the abdomen should be substituted for operation only in those cases in which serious disturbances in respiration or circulation contra-indicate laparotomy. Mild attacks of the disease, especially in children, should be treated conservatively. In acute cases presenting the picture of acute suppurative peritonitis operation is indicated. If no serous exudate is found a tampon should be applied. Conservative treatment is best for dry peritoneal tuberculosis with adhesions. In conclusion the author gives ninety references from the literature.

HESSE.

Friedman, L.: Retrograde Incarceration — Hernia "en W." *Surg., Gynec. & Obst.*, 1913, xvii, 97.
By *Surg., Gynec. & Obst.*

In the type of strangulation known as "retrograde incarceration," the incarcerated portion of a herniated organ lies, not in the hernial sac, but within the abdomen near the hernial constricting ring, while that part of the organ lying toward the periphery from the hernial orifice and within the sac is nearly normal or usually shows evidence of only moderate interference with its blood supply. The organs involved may be the appendix, fallopian tube, Meckel's diverticulum, omentum, and intestine (most often the small intestine). When the intestine is involved, two or sometimes three distinctly separate loops of gut are found in the hernial sac, while the incarcerated loop, or so-called "connecting loop," is within the abdomen near the hernial orifice.

Thrombosis of the mesenteric vessels and hæmorrhagic infarcts in the mesentery are present in severe cases of "connecting loop" incarceration. Clear, turbid, or bloody fluid is present in abdomen. The symptoms and diagnostic signs depend upon the length of the incarceration, and are as follows:

1. Large-sized tumor in scrotal region, sometimes asymmetrical.
 2. Colicky pain in lower abdomen on the side of the hernia; pain on pressure on side of hernia, immediately above Poupart's ligament.
 3. Rigidity above Poupart's ligament on side of hernia.
 4. Local tympany.
 5. Presence of sausage-like mass in lower abdomen on side of hernia.
 6. Perceptible asymmetry of lower abdomen, the hernial side being higher.
 7. Dullness on percussion in flanks due to fluid and perceptible fluid wave.
 8. Blumberg's sign of peritoneal irritation.
 9. Greater abdominal than scrotal tenderness.
- After opening the sac:
1. The presence of two or three distinctly separate loops of gut.
 2. Escape of fluid, clear or bloody, from the abdominal cavity.

Peus: A New Case of Hernia Subtransversalis

(Ein neuer Fall von Hernia labialis posterius; hernia subtransversalis). *Gynäk. Rundschau*, 1913, vii, 281.
By Zentralbl. f. d. ges. Gynäk. u. Geburtsh. s. d. Grenzgeb.

The author reports a case of hernia subtransversalis, operated on by von Franqué, thus adding one case to the ten hitherto published. Like von Winkel he differentiates hernia subpubica, hernia ischiadica and hernia subtransversalis or labialis posterior. In the third, the hernial opening is between the rectum, coccygeus, tuber ischii and m. transversus perinei. These perineal hernias are caused partly by the passing of the intestinal loops through congenital gaps in the pelvic floor. The gaps may be enlarged by lacerations during parturition and especially by forceps delivery. By the great strain upon the abdominal musculature intestinal loops or omentum may then be forced through. These hernias have the opening in the m. levator ani, and the sac is formed by skin, fat tissue, superficial and pelvis fascia, subserosa and peritoneum. Zuckerkandl and Ebner are of the opinion that perineal hernias occur only with congenital invagination of the peritoneum into the pouch of Douglas. The author considers this a predisposition but not a *conditio sine qua non*. Two congenital perineal hernias are described in the literature.

Von Franqué laid the hernial opening free, extirpated the sac, closed the opening with frontal sutures and pulled the levator ani over it to the os pubis without grasping the periosteum. The opening was on the outer border of the pubic part of the levator ani at about the height of the middle of the perineum and close beneath the transversa perinei. The patient has had no relapse for two years and a half. The findings before and after the operation are illustrated.

These hernias may be treated with trusses if there are no incarcerations and if the hernias can be replaced; otherwise operation is necessary. KNOOP.

Santucci, A.: A Rational Deep Suture for Bassini's Operation (La suture rationnelle du plan profond, dans le procédé de Bassini). *Clin. chir.*, 1913, xxi, 779. By *Journal de Chirurgie*.

The author states very truly that grave consequences may result from tying the sutures that unite the crural arch with the internal oblique and transversalis muscles. Such tying may cause gangrene of the parts tied, as the result of the mechanical action, and of the neighboring parts, as the result of the interruption in the circulation. The blood vessels that nourish the muscles run parallel to their fibers. Although it is true that the deeper the sutures are placed in the muscles the better from the standpoint of strength, there is, nevertheless, great danger of an extensive necrosis.

On this first point there can be no question—the sutures must be placed in tissue that is firm, and they must draw together without strangulating. To meet these requirements the author proposes substituting for the ordinary interrupted sutures a series of sutures in the shape of a U, the base of which should include the crural arch, and the arms of which should pass through the deep muscle and the aponeurosis of the external oblique muscle and be tied superficially to the latter. His plan is not bad *à priori*. It is to be feared only that by his method the suppression of the deep muscles would be accomplished less easily than by the usual technique. As a new argument in favor of his method the author adds that, in case of infection, the sutures, though deep in their action, are easy to get at.

PIERRE FREDET.

Gundermann, W.: The Significance of the Omentum in Physiological and Pathological Conditions (Über die Bedeutung des Netzes in physiologischer und pathologischer Beziehung). *Beitr. z. klin. Chir.*, 1913, lxxxiv, 587.

By *Zentralbl. f. d. ges. Chir. u. i. Grenzgeb.*

The omentum of the mammal is a peculiar, highly lymphatic, membranous organ developed from the excessive growth of the mesogastrium. Its function is not definitely known. Its importance as a reservoir of fat is doubtful. It is not an anchor for the transverse colon. It is, however, a regulator for the gastric vessels during physiological hyperæmia of the stomach. The author believes that under pathological conditions ligation of the omentum is the direct cause of post-operative hæmorrhage of the stomach and bowel, especially in elderly people the valves of whose omental veins are defective. It seems that the degenerated liver tissue following slight thrombosis of the portal veins is toxic to the gastric vessels which are overfilled after operation. Another function of the omentum is to serve as a place where collateral circulation is established in cirrhosis of the liver and uterine tumors. It has no movement of its own. The absence of the omentum decreases the resistance against peritoneal infection. Intra-peritoneal free omentum transplantation is possible only when asepsis is perfect and when there

are no adhesions. Foreign substances (carmin, cærulein) introduced into the abdominal cavity are partly absorbed through the diaphragm and its lymphatics within fifteen minutes. The remainder is fixed by the omentum and transported by phagocytosis through the omental lymph stream within twenty-four hours.

JOSEPH.

Schmieden, V.: Circumscribed Inflammatory Tumor Formation in the Pelvis, Originating from the Greater Omentum (Über circumscribte entzündliche Tumorbildung in der Bauchhöhle, ausgehend von Netz). *Berl. klin. Wchnschr.*, 1913, l, 908.

By *Zentralbl. f. d. ges. Chir. u. i. Grenzgeb.*

Schmieden compares cases described by Küttner of idiopathic tumor-forming fat necrosis of the omentum with a case in which the development of a tumor the size of a man's head extended over many months. The tumor could not be extirpated, and its growth was not influenced by exposure and incision. Finally a high grade intestinal obstruction resulted, so that an extensive operation was necessary (exclusion of the cæcum and ascending colon surrounded by the tumor growth, and lateral anastomosis of the lowest loops of resected small intestine that enter the tumor with the transverse colon). Only when the irritation, produced obviously by the passage of faecal material, had been excluded did a retrogression of the tumor take place. At the last examination (eight months after the operation) the tumor could not be palpated.

Schmieden is unable to explain the causes in the formation of the morbid entity in this case. He believes that it must be attributed to thrombotic processes with nutritional disturbances in the omental fat, emboli, hæmorrhages, or circulatory disturbances produced by torsions of small pieces of omentum with incomplete constriction. Adipose people are predisposed. In the differential diagnosis, beside real tumors, actinomycosis must be taken into consideration.

REINHARDT.

Frazier: Mesenteric Cysts, with Report of a Case of Sanguineous Cysts of the Mesentery of the Small Intestine. *J. Am. M. Ass.*, 1913, lxi, 97.

By *Surg., Gynec. & Obst.*

A review of the literature on the subject of mesenteric cysts is attempted, together with a complete report of a case observed by the author.

The origin of cysts of the mesentery is in many cases obscure. Many classifications have been offered by investigators but that which the author prefers is the one adopted by Moynihan. He classifies them according to their nature as: (1) serous cysts, arising either from a lymphatic dilatation or from hæmorrhages between the layers of the mesentery; (2) chylous cysts, probably the most numerous, containing a milky white fluid and due to a dilatation of some of the lacteals or chyloferous vessels; (3) hydatid cysts, due to the tænia echinococcus; (4) dermoid cysts; and (5) sanguineous cysts, the class to which the case reported belongs.

The cysts vary in size from that of a pea to the size of a man's head. They are usually oval in shape, their greater diameter being vertical. They are either uni- or multi-locular. The wall is composed of fibrous tissue and varies in thickness from a thin membrane to 1 cm. The character of the contents depends upon the origin of the cysts and also upon whether hæmorrhages have taken place into the cyst or not.

The symptoms depend largely upon the size of the cyst and upon its relation to the neighboring viscera. Many of the smaller cysts are discovered only at autopsy and caused no inconvenience during life. The symptoms which mesenteric cysts most commonly produce are pain, more or less severe, digestive disturbances, and symptoms of acute or chronic intestinal obstruction. Coincidentally there may be loss of weight and inanition and emaciation, and if operative measures are postponed too long peritonitis may develop from rupture of the cyst or the patient may die of inanition.

Percussion and palpation reveal the usual signs of abdominal tumor and fluctuation may sometimes be elicited.

The treatment, in all cases, should consist in operative measures. Theoretically there are four possible modes of procedure: (1) aspiration; (2) enucleation; (3) resection of the involved intestinal segment followed by excision; and (4) incision and drainage. The first procedure has become obsolete. Wherever possible the radical procedure should be attempted, but when there are acute symptoms of intestinal obstruction it may sometimes be necessary to merely incise and drain, as many of these patients with acute obstruction will not tolerate any but the simplest and most rapid operation.

The case reported is that of a man who fell eleven years previous to the operation and received a severe blow upon the abdomen. Subsequently he noticed a small tumor above the symphysis, which very gradually became larger. During the past year this growth had become more rapid. The operation showed a large mesenteric cyst near the ileo-cæcal valve and subsequent examination showed it to be of the sanguineous variety. The cyst was removed and a large piece of bowel resected with it. An uneventful recovery ensued. J. H. SKILES.

Cartolori, F.: Mesenteric and Retroperitoneal Blood Cysts (Sur les kystes hématiques mésentériques et rétroperitonéaux). *Clin. chir.*, 1913, xxi, 725. By Journal de Chirurgie.

This article, which is a critical study of the subject, includes an account of an unpublished case treated by Spangaro. A man 65 years old had a smooth, elastic and fluctuating subumbilical tumorous mass in the abdomen about the size of a seven months' pregnancy. The mass was slightly mobile but was not influenced by respiration. On operating, Spangaro found a cyst surrounded by the intestines and covered by peritoneum, on the surface of which were numerous large blood vessels. He tried to

enucleate it but it adhered so closely to the ureters that some of the posterior wall had to be left in. Its contents were a serosanguinous fluid and red blood clots. A few days later a fistulous opening appeared at the lower angle of the wound from which escaped a seropurulent fluid. The subject gradually lost weight and died four months after the operation.

The autopsy showed that the fistula led to a cavity in front of the colon. In this cavity were found remnants of the cyst that had not been removed.

Histological examination showed that the wall of the cyst was made up of old connective tissue, lymphoid tissue, and new, very vascular connective tissue. Its thickness varied from 2 to 8 mm.

The author believes that this was an old lymphatic cyst which had become bloody as the result of a chronic inflammatory condition of its wall.

PIERRE FREDET.

GASTRO-INTESTINAL TRACT

Carnot, P.: Movements of the Stomach and Duodenum Studied by the Perfusion Method (Les mouvements de l'estomac et du duodénum étudiés par la méthode de la perfusion). *Compt. rend. Soc. de Biol.*, 1913, lxxiv, 1265.

By Journal de Chirurgie.

By means of the perfusion method described by Carnot and Glénard, Carnot has been able to study the movements of the stomach and duodenum of the cat. According to this method, the detached mass of viscera, distended by a semiliquid substance, is immersed in Cloeke's oxygenated fluid or in defibrinated blood. Carnot studied the movements from the point at which they started to the point at which they passed the pylorus and went over into the duodenum.

On the fundus side the stomach contracts to form a veritable balloon confined below by the medio-gastric groove. The part of the stomach that is intermediate between the fundus and the prepyloric antrum is equally contracted. During activity the stomach takes on an hour-glass form which is modified by the peristaltic waves passing from the cardia to the pylorus. It is an exaggeration of this physiological phenomenon which gives rise to intermittent tension of the epigastrium when the pylorus is obstructed. The prepyloric antrum is bounded on the side near the stomach by a groove of contraction similar to the mediogastric ridge, and peristaltic waves tend to expel its contents through the pylorus. In the duodenal bulb there are antiperistaltic movements tending to exert on the pyloric ring pressure equal to that of the pyloric antrum. The pylorus itself does not participate in these contractions directly. When it opens the duodenal bulb contracts and is then moved by peristaltic contractions which force the bolus of food down into the small intestine.

The perfusion method makes it possible to determine exactly by cinematography the movements of

the gastroduodenal apparatus, an apparatus that, on the basis of its partial contractions, has three distinct parts; i. e., the fundus, the prepyloric antrum, and the duodenal bulb. This method confirms also the results obtained by radioscopy after the ingestion of bismuth. **PIERRE CRUET.**

White, F. W., and George, A. W.: The X-Ray Method in Diagnosis of Gastric and Duodenal Ulcer. *Boston M. & S. J.*, 1913, clxix, 157.
By Surg., Gynec. & Obst.

According to the personal experience of the authors, X-ray methods add materially to the conciseness of diagnosis in gastric and duodenal ulcer. Serial radiographs are used as a basis for conclusions, the screen observations serving to give a general survey of conditions and to show the facts about mobility and motility.

Radiological signs that may accompany ordinary gastric ulcer are: local spasm, seen most often when the stomach is nearly empty; a reflex pyloric spasm of variable duration; vagotonia; and, in half of the cases, residue after six hours, due to spasm of the pylorus, irregular peristalsis or organic obstruction. In hour-glass contractions following ulcer the segmentation is clean cut and constant, and the stomach is drawn to the left by contraction along the lesser curvature; in adhesions to the liver and gall-bladder the stomach is drawn to the right and fixed there. Penetrating ulcers give a characteristic protrusion of the bismuth, with or without a gas bubble at the top.

In duodenal ulcer the shadow of the first portion of the duodenum undergoes change in form and outline, and gastric motility is affected. Constant filling defects in the caput duodeni are recognized from a series of plates made to show this structure to the best advantage in each individual case. Frequent use is made of the lateral ray projection, with the patient lying on the right side. Worm-eaten edges in the bismuth-duodenal shadow are common in duodenal ulcer but may be present also in adhesions and malignancy. The gastric motility in duodenal ulcer is variable and the actual time of emptying depends upon a number of factors the result of which in a given case may be anywhere from a marked hypermotility to a grave degree of stasis.

It is predicted that this line of work will become much more valuable in the future as the significance of the various X-ray findings becomes more firmly established. In the authors' hands the method at present is considered very helpful if not indispensable.

HOLLIS E. POTTER.

Mills, R. W. and Carman, R. D.: The X-Ray in the Diagnosis of Gastric Ulcer and Its Sequelæ. *Surg., Gynec. & Obst.*, 1913, xvii, 1.

By Surg., Gynec. & Obst.

According to the authors there is need of co-operation on the part of the internist and the röntgenologist in the utilization of the X-ray for purposes of gastro-intestinal diagnosis. A discus-

sion is then given of gastric anatomy and physiology as revealed by the X-ray. The changes in the stomach as indicated by the X-ray that may indicate the presence of gastric ulcer are then discussed under four headings; i.e., (1) changes in tonus; (2) changes in position and form; (3) changes in peristalsis and motility; and (4) the relation that areas of pain, tenderness, and mass bear to X-ray findings.

Changes in tonus give different X-ray findings according to the part of the stomach that is involved. Of changes in tonus resulting from ulcer of the pars pylorica nothing is known as yet. Direct abnormalities of tonus in the pars cardiaca and pars media are due to the ulcer. Spasm of the circular muscle fibers of the stomach at the level of the ulcer result in the formation of incisuræ on the greater curvature. The authors discuss the specificity of such incisuræ, their size and form, and the degree to which the stomach is divided by them. They give also criteria as to the genuineness of the X-ray picture of incisuræ, and a discussion of pseudo-incisuræ and the diagnostic value of the real incisuræ.

Changes in the position and form of the stomach may result from ulcer. When they occur as the result of causes within the stomach, the stomach as a whole is in a left median position. This position may be due to an acquired atony. The dislocation of the pylorus to the left may be the result of contractures. Indications of change in form of the stomach due to gastric ulcer are the visualization of the ulcer crater as a projection on the periphery of the gastric shadow, the "nischen sign," and the formation of the hour-glass stomach. All of these are described and similar phenomena not indicating ulcer are discussed. When changes in position and form result from uncompensated obstruction of the pylorus by ulcer, the stomach occupies a central position as a whole and is laterally enlarged, especially to the right of the median; the gastric residue is also in a central position. If the ulcer obstruction is compensated, the findings are not characteristic. In such cases the stomach is enlarged but normal in position and form.

Changes in peristalsis and motility may denote the presence of gastric ulcer. In the case of non-obstructive ulcer there are no characteristic changes in peristalsis though the peristalsis may be increased. Antiperistalsis is discussed in its relation to non-obstructing ulcer of the pars pylorica. Delayed motility is suggestive of ulcer. In cases of uncompensated ulcer of the pylorus, hyperperistalsis may at some time be the rule and there may be marked delay in the motility.

Under the heading relation of areas of pain, tenderness, and mass to X-ray findings are discussed the necessity for care in making deductions, the possibilities as to the relation of pressure-sensitive loci to the stomach shadow, the causes of ulcer pain and tenderness, hypertension, and reflex irritation of the parietal peritoneum. Hypertension plus hypersensibility, according to the authors, is the cause of unlocalized ulcer pain. As a diagnostic aid it is

useless because unlocalized. Pressure tenderness is also discussed. Gastric ulcer is not intrinsically painful. Pressure tenderness due to a reflex does not as a rule correspond to the ulcer site. Irritation of the parietal peritoneum as a result of ulcer perigastritis gives, as a rule, definite information as to the location of the ulcer and adds to the X-ray findings if it corresponds to the site indicated by the X-ray. A palpable mass of ulcer origin probably corresponds to the ulcer site because of associated perigastritis and parietal peritoneum irritation.

The article is illustrated with numerous radiographs and is followed by a list of references to the literature of the subject.

Röpke, W.: Chronic Gastric Ulcer in the X-Ray Picture of the Air-Inflated Stomach (Das chronische Magengeschwür im Röntgenbilde des luftgeblähten Magens). *Mitt. u. d. Grenzgeb. d. Med. u. Chir.*, 1913, xxvi, 307.
By Zentralbl. f. d. ges. Chir. u. i. Grenzgeb.

Röpke is enthusiastic in regard to the X-ray examination of the air-inflated stomach. While the inflation with carbon-dioxide gas is dangerous because it extends the stomach suddenly and without any regard to its size, the careful introduction of a sound and inflation with air is quite harmless and is always permissible provided that at least a month has elapsed since the last free hæmorrhage.

With the aid of excellent X-ray pictures the author first describes the appearance on the plate of the normal stomach when inflated with air. When completely inflated its outline is a curved smooth line; when incompletely inflated, its outline shows indentations and the folds in the stomach wall are plainly visible. A stomach with a simple non-perforating ulcer when inflated has a very characteristic appearance in the picture, and by the air-inflation method in most cases the details are more clearly brought out and the whole picture better defined than by the bismuth method. A sharp constriction in the stomach picture, together with knotted or oblique band-like shadows, or a solid shadow on the lesser curvature either connected with the band-like shadows or at the end of the knotty shadows may be regarded as practical proof of the presence of a gastric ulcer, particularly if at the same time the clinical history has indicated such a condition. If the ulcer has penetrated into the surrounding tissue and organs, the X-ray picture is different and also in this case is so characteristic that a diagnosis can be made from it with certainty. In such pictures the author noted more or less clear areas within the outline of a large, solid shadow which encroached upon the lesser curvature. On operating, these clear areas were found to be the defects in the stomach wall where there had been a penetration through the indurated ulcer area into the left lobe of the liver and into the pancreas.

In most cases the air-inflation method requires only one picture to bring out the details of size, form, and position of the stomach. With the bis-

moth-meal method these points in the majority of cases can be determined only after a number of pictures have been taken with the patient in different positions. The air-inflation method, however, does not give any information in regard to the functional activity of the stomach, and for this the bismuth method will have to be used. In all of the cases that he reports the author was able by means of the air-inflation method to make a positive diagnosis both of simple indurated ulcers and those that had perforated into the surrounding tissues.

VON TAPPEINER.

Steinharter: A Preliminary Note on the Experimental Production of Gastric Ulcers by the Intravenous Injections of Clumped Colon Bacilli. *Boston M. & S. J.*, 1913, clxix, 81.
By Surg., Gynec. & Obst.

An emulsion of colon bacilli in the presence of free hydrogen ions, the author states, is agglutinated in from one to four hours when incubated at body temperature. Gastric juice of high acidity possesses this agglutinating power. With these facts as a basis, such an emulsion, when injected into the ear vein of a rabbit, has been followed by the formation of a gastric or duodenal ulcer within 24 hours.

The method of preparing the emulsion was this: active strains of colon bacilli in broth emulsion were agglutinated with a weak solution of active acid and hydrochloric acid; 2 cc. or 3 cc. of this emulsion were injected into each of six rabbits, and in each an ulceration of the stomach or duodenum was afterwards found.

Many important questions, such as the method of action of the colon bacilli (whether it is mechanical or toxic), whether or not it has a selective action on the stomach, or whether other organisms will behave in the same way, remain to be treated in a later communication promised by the author.

R. W. FRENCH.

Deaver: Posterior Gastrojejunostomy in Acute Perforative Ulcer of the Stomach and Duodenum. *J. Am. M. Ass.*, 1913, lxi, 75.
By Surg., Gynec. & Obst.

This paper emphasizes the great importance of early diagnosis of a perforation of the stomach or duodenum and the imperativeness of an immediate operation.

The diagnosis of an acute perforation is made mainly upon three things: first, the pain; second, the rigidity; and third, the history of previous indigestion of ulcer type. The pain is very intense, and very sudden in appearance. There may have been premonitory pains of great severity but the pain of perforation is agonizing and unbearable. It is abdominal, not pelvic, and usually in the mid-abdomen, epigastrium or hypochondrium, although occasionally radiating to the iliac fossa or back.

General rigidity of the abdominal muscles sets in at once after perforation. The rigidity is of the

extreme type, often called board-like. It is most marked in the upper abdomen. With the rigidity there is extreme tenderness, which is first located over the site of the perforation, but with the rapid spread of peritonitis other areas of peritoneum become sensitive to pressure and so the tenderness often becomes confusing. In perforated duodenal or gastric ulcers particularly, the infection is apt to spread along the paracolic grooves into the right iliac fossa. When the patient is first seen a few hours after the perforation the tenderness may be as marked over the region of the appendix as elsewhere and so lead to a diagnosis of perforative appendicitis.

A history of previous stomach or intestinal trouble can usually be obtained, although many times the patient is in such agony that the history must be obtained from friends or relatives. Occasionally, however, no history pointing to the presence of an ulcer can be elicited. A history of prior abdominal trouble is of assistance in making the correct diagnosis, but the absence of such a history does not by any means exclude the diagnosis of perforation.

These are the important symptoms and signs of perforated ulcer, and the other signs and symptoms usually described are either of minor importance as regards diagnosis or they appear only at a time when it is already too late to help the patient. The temperature, pulse, and respiration are sometimes changed slightly early but not to any diagnostic degree. Distention, accumulation of fluid in the abdomen, and the subsidence of peristaltic movements are all signs which are of prognostic, but not of diagnostic, importance. No case should be allowed to wait until these signs appear, as they foretell only too surely the approaching end. Free gas in the abdominal cavity and the obliteration of liver dullness also show that the case has almost certainly passed beyond the help of the surgeon. Leucocytosis is usually present early but may be slight.

In treatment of a perforation of a gastric or duodenal ulcer the important thing is to operate and to operate early. The majority of cases operated upon during the first twelve or eighteen hours recover while the cases that have gone over twenty-four hours usually succumb. The line of treatment adopted by the author was as follows: (1) closure of the ulcer; (2) plication of the duodenum to obliterate its lumen and fortification of this area by covering with the gastrohepatic and gastrocolic omentum; (3) posterior no-loop gastrojejunostomy; (4) tube drainage of the pelvis through a suprapubic stab.

The after-treatment consists in the sitting posture, continuous proctoclysis, and the prohibition of everything by mouth until peristalsis has been re-established as evidenced by auscultation and by the passage of flatus. The stomach tube is used freely for vomiting, regurgitation, or gastric distention. The administration of food is attempted very cautiously, beginning with albumin water. No purgatives are used but a cleansing enema is given the third day after operation.

J. H. SKILES.

Truesdale: Cancer of the Stomach. *Boston M. & S. J.*, 1913, clxix, 44. By Surg., Gynec. & Obst.

The author divides surgery of the stomach for cancer into three divisions:

1. The exploratory operation done to establish the diagnosis or to determine the operability of a palpable tumor. That this procedure is too infrequently used is obvious from the number of inoperable cases that come to surgeons. There is too often more reluctance on the part of the surgeon to do this operation and more on the part of the patient and his physician to have it done for suspected cancer, than to prove a palpable cancer inoperable.

The first stage of pyloric obstruction is due, not to the cancer *per se*, but to the tumor plus the pericancerous inflammation. Under these circumstances, conservative treatment yields results immediately good but ultimately disastrous. The microscope, chemistry, and the X-ray are all valuable in diagnosis, but the personal history, more than any other factor, must be depended upon mainly to furnish evidence for or against exploratory laparotomy.

2. The palliative procedures occupy but a small place in surgery of the stomach for cancer. The author believes that the excision of a large tumor-mass plus a gastro-enterostomy is preferable to a gastro-enterostomy alone as a palliative procedure.

3. The radical operation, which consists of partial gastrectomy and gastro-enterostomy. Wide margins of healthy tissue should be included, together with a complete excision of the lymphatic zones draining the infected area.

R. W. FRENCH.

Thomson and Graham: Fibromatosis of the Stomach and Its Relationship to Ulcer. *Edinb. M. J.*, 1913, xi, 7. By Surg., Gynec. & Obst.

Fibromatosis may be localized or diffuse, but it is the localized form which, from a clinical point of view, is the more important to differentiate from cancer. This form nearly always commences in the vicinity of the pylorus and spreads from there towards the cardia, usually, but not always, showing a preference for the lesser curvature. The external appearance of the stomach shows marked changes; the normal area is flaccid and collapses readily, whereas the affected portion is rigid and densely hard like gristle. The peritoneal surface, if free from adhesions, is white, pearly, and smooth. The diseased mucosa is usually firm and unyielding, closely adherent to the submucosa. It presents a hillocky surface which stops abruptly at the pyloric ring but gradually merges into the normal towards the cardia. The submucosa is converted into a thick, solid, tough, white tissue, not so dense as a cheloid, but resembling the consistence of a hard fibroma. The layer is made up of uniform fibrillated connective tissue with here and there collections of lymphocytes in the vicinity of the muscularis mucosæ. The muscularis shows a marked hypertrophy of the circular fibers with characteristic segmentation, being divided into bundles by septa of white fibrous tissue continuous with the fibrous tissue of

the submucosa. The serous and subserous coats are little altered as a rule.

The most striking fact in the pathogenesis of fibromatosis is the apparently invariable association with ulcer or ulceration of the mucosa. As regards the relation of fibromatosis to cancer they suggest that an ulcer is the primary lesion, which is followed by fibromatosis, and that, finally, a cancer originates at the edge of the ulcer. Clinically the features are those of ulcer. Hæmorrhage was a prominent feature in only one case.

Operative treatment: Where a diagnosis can be made and cancer excluded, the authors advise resection of the affected part. A reasonable alternative in weak patients is gastro-enterostomy and at the same time removing several glands from the lesser curvature. If these show the presence of cancer, the resection should be carried out after a suitable interval for recuperation. If the disease does not lend itself to radical treatment, then relief of symptoms may be had by gastro-enterostomy, or if impracticable, by jejunostomy.

R. W. McNEALY.

Janeway: The Relation of Gastrostomy to Inoperable Carcinoma of the Œsophagus, with a Description of a New Method of Performing Gastrostomy. *J. Am. M. Ass.*, 1913, lxi, 93.

By Surg., Gynec. & Obst.

A plea is made by the author for the earlier performance of gastrostomy on cases of inoperable carcinoma of the œsophagus before the patient has become emaciated from inanition. An early operation not only gives the patient a longer period to live but also relieves the cancer from the constant stretching and irritation caused by swallowing. The main objections usually raised to the performance of gastrostomy are the following: (1) the opening may leak; (2) the new fistula which leads to the stomach is permanently lined with granulation tissue and hence may cause some discharge; (3) there may be some irritation in the region of the skin; and (4) the annoyance of wearing a tube constantly.

The most serious of these objections is the possibility of leakage. This can well be prevented by following the procedure invented by Senn, which consists in invaginating a small cone of the stomach wall around a tube and then suturing the base of the cone to the parietal peritoneum. This forms a valve which prevents the outflow from the stomach.

The establishment of a permanent fistula requires an epithelial lining for the fistulous tract. This is accomplished by a procedure described by the author. An incision is made parallel with the rectus fibres a short distance to the left of the median line and 3 or 4 cm. below the costal margin. The fibres of the rectus are not divided but are separated bluntly, the posterior sheath of the rectus cut through, and the peritoneal cavity opened. The anterior wall of the stomach is then pulled through the wound and an incision 3 to 4 cm. long made with a perpendicular incision 1 cm. long at either end of the first incision. This forms a flap of stomach wall 3 cm. by 1 cm., and

by sewing the opposite edges of the opening together transversely to the direction in which the incision 3 cm. long was made, a hollow prolongation of stomach wall is formed, which is about 5 cm. long. This tubular projection may then be fastened into the abdominal incision and the outer end sutured to the opening in the skin. The rectus muscle acts like a sphincter and no leakage occurs under ordinary circumstances.

J. H. SKILES.

George: The Positive Diagnosis of Duodenal Ulcer by Means of the Röntgen Ray. *Am. Quart. Röntgenol.*, 1913, iv, 187.

By Surg., Gynec. & Obst.

To obtain the most valuable evidence of the presence of duodenal ulcer, the actual deformity, slight though it may be, must be demonstrated as constant on a series of radiographic plates. To date, the frequent failures here and abroad result from too great a dependence upon such data as can be observed with a fluoroscope.

The author assumes that the observation of Germain, that the first portion of the duodenum has a very constant shape and structure unless it is diseased, is correct. Also that a duodenal ulcer, which is producing symptoms, involves the mucularis early, becomes somewhat callous, and produces a real defect in the duodenal outlines.

The "caput duodeni" is sometimes better filled in the standing position, sometimes in the prone position. Not infrequently, to make it quite visible, plates must be made with the light directed laterally through the body from the left side, the patient lying or standing. This is most often true in the steer-horn type of stomach or in special conditions in which the duodenum projects backward and is hidden behind the stomach. This method has added a great deal to the accuracy of duodenal inferences as well as to the radiographical knowledge of the posterior wall of the stomach.

In conclusion the author is satisfied in having made minor incorrect inferences in only three of fifty-nine operated cases of duodenal ulcer, and major incorrect inferences in none. This showing he believes makes his results practically positive.

HOLLIS E. POTTER.

Bunting and Jones: Intestinal Obstruction in the Rabbit. *J. Exp. Med.*, 1913, xviii, 25.

By Surg., Gynec. & Obst.

In a former paper the authors stated their belief that the early death in high intestinal obstruction is due to the absorption of a toxic duodenal secretion. If closed loops be made of lengths of ileum and jejunum in a fasting animal, no secretion occurs into these loops, while the duodenal loop becomes distended with a faintly straw-colored alkaline fluid.

The only difference between the upper and lower segment of the small intestine of the rabbit is the presence of Brunner's glands. It seems justifiable to conclude that the secretion found in the duodenal loop comes from these glands.

J. F. CHURCHILL.

De Quervain: Errors of Diagnosis in Appendicitis
(Des erreurs de diagnostic dans l'appendicite). *Rev. méd. Suisse romande*, 1913, xxxiii, 513.
By *Journal de Chirurgie*.

One of the greatest criticisms made of the radical operation for appendicitis is that there may have been an error in diagnosis. However, the radical operation is the only method of lessening the mortality of the disease, and out of 1723 cases operated on for appendicitis there were but ninety-four in which there was no lesion in the appendix.

Ten times the error was on account of perforation of gastric or duodenal ulcers which should be readily recognized from the symptoms of perforation, extreme initial pain, and general muscular rigidity.

Twice the error was due to intestinal perforation in the ileocecal region, twice to intussusception, once to acute pancreatitis, and once to acute occlusion of the mesenteric vessels. It must be differentiated from cæcum mobile, typhlatony, typhlectasy, Lane's kink. Five errors were due to a pneumococcus peritonitis in children from four to ten. Liver abscess, subphrenic, non-appendicular abscesses, and intestinal worms, have also caused errors. In three cases, cholecystitis, and in one, renal lithiasis were mistaken for appendicitis. There were nine cases in which appendicitis was confused with acute salpingitis; nine cases, with tubal abortions and rupture of tubal pregnancies; one, with torsion of the ovary; and fourteen, with torsion or rupture of ovarian cysts.

In half of these cases the operation was as urgent as if it had been appendicitis. In a fifth, the intervention, if not urgent, was justifiable, and the best thing to do. In the rest the operation was unnecessary, but rarely caused death. These facts are such that they urge the surgeon to operate without fear for appendicitis.

PAUL MATHIEU.

Pólya, J.: Cases of Appendicitis, Cholelithiasis, and Pericholecystitis, Showing the Clinical Picture of Ulcer of the Stomach or Duodenum
(Fälle von Appendicitis, Cholelithiasis und Pericholecystitis, welche das Symptomencomplex von Ulcus ventriculi und duodeni darboten). *Budapest kir. Orvose. Értésítője*, 1913, ii, 377.

By *Zentralbl. f. d. ges. Chir. u. i. Grenzgeb.*

The author reports seven cases in which the history of typical pains, hæmoptysis, the clinical symptoms, and the X-ray picture indicated stomach or duodenal ulcer, but on operation there was found either chronic appendicitis, dilatation of the gall-bladder, adhesive pericholecystitis, or gall-stones. These cases show: 1. That in cases in which pain in the stomach has persisted for a long time in spite of internal treatment, operation should be undertaken, for, even if there is no ulcer, some condition will certainly be found which will explain the pain and which can be relieved surgically. 2. That diseases of the appendix and gall-bladder may lead to superficial ulceration from which hæmoptysis may arise even though it may not be pronounced enough to be demonstrable on operation. 3. That it is

possible that some of the pain observed after an operation for ulcer is caused by disease of the appendix, gall-bladder, or other abdominal organs.

PÓLYA.

Ducoux: Hydro-Appendicitosis (De l'hydro-appendicite). *Rev. de gynéc. et de chir. abdom.*, 1913, xx, 143.
By *Journal de Chirurgie*.

"Hydro-appendicitosis" is the name given by Jaboulay to the condition of the appendix which becomes suddenly and intermittently distended by the secretions of its mucosa. The symptoms are those of appendicitis.

Ducoux has collected eleven cases of this kind, two from Paris (reported by Petit and Walther) and nine from Lyons. Three of these were Jaboulay's.

In hydro-appendicitosis the appendix is turgid, swollen, and red, and from 8 to 12 cm. in length. It has been compared in appearance to a penis, a small intestine, and a banana, and when irregular, to a mandarin or a hydrocele. In some cases there may be one or two swellings resembling cysts. There are frequently adhesions fixing the appendix to the cæcum or bending it toward the omentum, and the meso-appendix is frequently œdematous. The walls are very thin and care must be taken when separating adhesions to avoid rupturing them. The liquid from the appendix in one of Jaboulay's cases caused tuberculosis in a guinea pig. In one of Petit's cases drops of the liquid which fell into the wound produced an ulceration, apparently tuberculous, which was hard to cure. By microscopic examination Jaboulay found in one case giant cells in sections of the appendix. In several cases miliary tubercles were found in the cæcum and intestine. Accordingly it seems logical to classify "hydro-appendicitosis" as an atrophic tuberculosis of the appendix accompanied by dropsy.

Clinically there are three forms of hydro-appendicitosis; i. e., a latent form, with digestive trouble; a form in which there is tumor, and a form characterized by repeated attacks of appendicitis. The last is the most common. The form characterized by tumor must be differentiated from cancer and ileocecal tuberculosis.

The treatment advised is resection of the appendix. Special care should be taken to keep the fluid contents from coming into contact with the wound. The incision must be large. Jaboulay recommends a transverse incision beginning at the lower third of the incision of Jalagnier and extending toward the crural arch. The prognosis is grave, not so much on account of the lesions of the appendix as on account of tubercular lesions in the lungs that frequently accompany this disease. GEORGES LABEY.

Solieri, S.: Gastric Hyperacidity of Appendicular Origin (Sur la gastropathie hyperacide d'origine appendiculaire). *Rev. osp.*, 1913, iii, No. 10.
By *Journal de Chirurgie*.

Moynihan in 1910 was among the first to describe an appendicular dyspepsia. This disease occurs

most frequently between the seventh and fifteenth years. It has an insidious onset, rarely following an acute attack, and its symptoms are usually like those of gastric ulcer. There is gastric pain soon after meals, which is not radiating, and which is frequently accompanied by acid vomiting and marked hyperchlorhydria. Tenderness to pressure is felt in the epigastric region but none elsewhere except when epigastric pain is caused by pressure at McBurney's point. On operating on a case of this kind, Moynihan found the exterior of the stomach normal in appearance. He noted, however, intermittent spasmodic pyloric contractions. Solieri in a similar case first performed a gastro-enterostomy with no beneficial result. Appendectomy performed later, however, resulted in a complete cure. The appendectomy followed a typical attack of appendicitis with abscess formation and faecal concretions four months after the gastro-enterostomy was performed. Two months later the patient had gained 12 kilos and had not had any further gastric distress.

AMEUILLE.

Cargile: Grape Seeds in a Pelvic Abscess. *South. M. J.*, 1913, vi, 330. By Surg., Gynec. & Obst.

The author reports the case of an 11 year old boy who, after having occasional attacks of what was called indigestion over a period of several years, developed a pelvic abscess. This was drained and 23 grape seeds escaped in the pus. One seed was seen in the faeces. An investigation in the library of the Surgeon-General's office fails to reveal a similar case. The nearest to it is one in which 122 small shot escaped through the appendix. Another interesting feature of this case was the absence of pain. The author states that he had confined the mother twice and that, while she could feel the contractions, both labors were absolutely painless. In no other respect was the mother abnormal.

C. H. DAVIS.

Cheever, D.: Etiology and Significance of Pericolic Membranes. *J. Am. M. Ass.*, 1913, lxi, 248. By Surg., Gynec. & Obst.

The etiology of pericolic membranes has not been settled beyond dispute. The author, however, considers the origin of these membranes to be of a dual nature. On the one hand he places the membranes resulting from congenital malformations, and on the other hand, those which are due to peritoneal irritation. In support of his theory that many of these membranes have a congenital origin he calls attention to the fact that the very nature of the thin diaphanous veil which constitutes the membrane in many of the cases would suggest that it is a membrane of developmental rather than of inflammatory nature; also the study of these membranes in the foetus and in the new-born has added overwhelming evidence in favor of the developmental theory in many of these cases. Membranes appearing in the foetus or the new-born could hardly come from peritoneal irritation or inflammation unless we

accept the unproved theory of foetal peritonitis. As to exactly what step of the development of the foetus is responsible for the formation of these membranes the author is not able to state. He is inclined to believe that they are formed during the descent and rotation of the caecum from beneath the liver.

Of what pathological significance are pericolic membranes? Future investigation will probably tell us just how much intestinal disturbance can be attributed to these abnormalities. At present there is a marked difference of opinion among surgeons as to what train of symptoms they may produce. The present accepted treatment of the condition seems to be the division of the membranes by the thermocautery.

J. H. SKILES.

White, S.: Cancer of the Colon. *Brit. M. J.*, 1913, ii, 57. By Surg., Gynec. & Obst.

Cancer of the colon is usually a primary disease. Occasionally, however, the bowel becomes involved by extension of the disease from an adjacent viscus such as the stomach. Cancer of the colon is most common between the ages of 40 and 65. Two varieties of the disease require a special description. One, the sclerosing type, is so frequent that it may be regarded as the typical form. Growing very slowly, it leads to an annular constriction of the bowel which, if the patient lives long enough, will end in obstruction. The mesenteric glands are affected late. The second variety, which occurs in a minority of cases, is of the fungating type. There is extensive infiltration of the walls of the bowel and, in addition, a fungating mass sprouts into the lumen of the bowel. There is no constriction of the bowel. It occurs more often in young people and is characterized by rapid growth, early dissemination, bloody stools and cachexia. There is no definite symptomatology and in the annular sclerotic type obstruction may be the first symptom. In obstruction from cancer of the colon distention precedes vomiting. Marked peristaltic movements of the colon are common. The author reviews 26 private cases of colectomies for cancer. Fifteen of these came to him with acute or subacute obstruction and all were relieved by colostomy, the growth being removed from 10 to 21 days later. Four patients died, two from pulmonary embolism, one from defective union of the bowels, and one from metastasis. Thirteen patients remain in apparent good health, eight of them after from 14 to 4 years. Five were operated on within the last 3 years. Colectomy should never be performed where intestinal obstruction is present. Patients beyond 70 years of age are poor risks. White advises colostomy or short circuiting for cases unsuitable for colectomy.

Under operative technique the author advises, first, a thorough exploration of the abdominal cavity for evidence of metastasis before the operation is undertaken. Second, if the disease is too advanced, a short-circuiting, or, if this is not possible, a colostomy. He takes up the method of uniting the bowel but says there is no one way for all cases. There are

few operations in which good technique counts for so much, and every step in the procedure should be carried out deliberately and with infinite care. Three cases are reported as typical of the disease.

M. S. HENDERSON.

Aubertin, C. and Beaujard, E.: The Action of X-Rays on Polyadenomas of the Intestine (Actions des rayons X sur les polyadénomes de l'intestin). *Bull. et mem. Soc. méd. d. hôp. de Par.*, 1913, No. 22, 1221.
By Journal de Chirurgie.

Aubertin and Beaujard had an opportunity to compare two biopsies made eighteen months apart in the case of a man 34 years old suffering with polyadenomatosis of the large intestine. The first specimen was obtained after a few treatments by radiotherapy, the second after 25 treatments, when the symptoms were diminished and rectoscopy showed diminution in the size and number of the polyps. The authors made an histological study of the two specimens and believed that they could attribute to the action of the X-rays a decrease in the size of the glandular crypts, the disappearance of the cyst-like formations, suppression of the cells filled with mucus, and a restriction in the amount of stroma. These changes they interpreted as an histological amelioration of the condition.

MAURICE CHEVASSU.

Kienböck, R.: The X-Ray Diagnosis of Colitis Ulcerosa (Zur Röntgendiagnose der Colitis ulcerosa). *Fortschr. a. d. Geb. d. Röntgenstr.*, 1913, xx, 231.
By Zentralbl. f. d. ges. Chir. u. i. Grenzgeb.

According to Stierlin, colitis ulcerosa shows the following characteristics in the X-ray picture: The diseased portion of the bowel is free from large quantities of bismuth and shows only a few longitudinal bismuth shadow-lines; the border lines of the intestine are parallel, without marks of saccules, and enclose between them a very clear area which has an increased gas content; this picture is constant. Stierlin explains the condition as being a hyperæsthesia of the quickly emptying colon with residue remaining upon the ulcers of the intestinal wall in diverticuli or long-drawn-out lines. Schwartz and Novascinsky report similar findings and give similar explanations. Kienböck reports in detail three cases of colitis ulcerosa, two with tuberculosis and one with dysentery. His conclusions are as follows:

There are two distinct types. The picture of Type I shows a narrow bowel almost without saccules, and with short, wavy shadow-lines which are woven into veils or clouds; the bowel often shows spastic contraction or is of an inflated club shape with a dark margin; in this form the intestinal wall is still mobile. The picture of Type II is that of a broad cylinder of an even thickness, without saccules and with narrowly dentated outlines, a form characterized by rigid infiltration of the walls and the formation of ulcers. The picture of the empty bowel is similar to that of normal digestion. With

the ulcerative process, insufficiency of the Bauhin's valve, adhesions, kinkings, and stenosis are frequent.

HOFFMANN.

Beach, W. M.: A New Operation for Hæmorrhoids. *Pittsburgh M. J.*, 1913, i, 1.
By Surg., Gynec. & Obst.

The author reviews the anatomy of the rectum and anal canal. He protests against the general use of the word "orifice" as applied to the anus and insists that the words "anal canal" should be substituted. The blood supply of the anal canal is derived largely from the superior hæmorrhoidal artery, a continuation of the inferior mesenteric artery. The superior hæmorrhoidal descends from the rectum to the superior part of the anal canal where it terminates in a plexus of veins. These veins are, very thin-walled and are covered only by mucosa. Therefore they are very easily distended by any obstruction to the outflow of the blood.

The author objects to the operations commonly used in the radical treatment of hæmorrhoids. His objections are, that the operation is either too destructive of the mucous membrane and the nerve endings enclosed therein, or it is not radical enough to effect a permanent cure. He criticises especially the Whitehead operation because it removes such a large area of epithelium that contains sensitive nerve endings having a special function to perform in the control of the sphincter ani. He criticises the ligature method because of the sloughing which occurs beyond the constriction and the attending pain. He claims also that at times by the ligature method only the overlying mucosa and not the whole pile is included and as a result the condition tends to recur. He censures the use of the clamp and cautery because of the pain and suffering which he claims follow in many cases and may extend over many weeks.

The operation that Beach recommends is as follows: The patient is anesthetized either generally or locally and placed in the lithotomy position. The tissues of each quadrant are then seized with the forceps and by traction are brought into view. A single-pronged tenaculum is passed through the diseased tissues and the entire mass is removed with curved scissors. Any distended veins that have been left are then removed with a curette. The incised mucosal edges will usually approximate. Ragged edges are trimmed away. To obviate post-operative hæmorrhage, a gauze-covered tube one inch in diameter is inserted through a bivalve speculum. This acts not only as a hæmostatic but also as a splint.

J. H. SKILES.

Smith: A Description of the Enteroptotic Woman. *Surg., Gynec. & Obst.*, 1913, xvii, 71.
By Surg., Gynec. & Obst.

Visceral prolapse in woman is always attended by other closely associated structural abnormalities. On this basis, these women may be divided into two groups. In the one are placed those who in early life were well nourished, more or less sturdy of form

and firm of tissue, who had deep chests, capacious abdomens, and retentive abdominal walls, but who now have considerable relaxation of tissue, muscular weakness, a changed configuration of body, and sometimes loss of weight, the so-called acquired enteroptosis. The visceral prolapse itself is on the whole less in degree than in the second group. The symptoms are oftentimes quite as severe.

The second or congenital group includes those women who from childhood up have been frail of form and lacking in vigorous development. They have little fat, the tissues are soft and relaxed. These are the fundamental characteristics; other changes follow. These women form a distinct type. The chest is small, shallow, and contracted at its lower end. The neck and limbs are as a rule longer than usual. The abdomen is on the whole less prominent than in women of the first group. Muscular insufficiency is common and shows itself in changes in the spinal curve, round shoulders, and flat foot, which commonly express fatigue and are valuable guides in estimating the health of the individual. These are in general much less fixed than the changes in the chest and improve as the woman regains her health. They are responsible for much of the pain. The study of the chest gives a valuable clue to the natural vigor and the early nutrition, for the chest above described can follow only primary defects and long-continued poor nutrition in early life. Intelligent attention to the nutrition of children is necessary if the conditions which follow are to be prevented. The author gives plates of the stomach and bowel and points out the abnormality, mobility, and relaxation.

The two groups described cannot be sharply divided — many are of mixed type — but the purer forms of each are so different as to make a distinction necessary. In the first group fundamental defects are not dealt with; in the second they are, and any treatment undertaken in adult life necessarily has its limitations. Many cases of lesser degree, with a good nervous system, especially when the strain of life is not severe, will have good health. Many may be improved by proper treatment.

LIVER, PANCREAS, AND SPLEEN

Jaugeas: Radioscopic Examination of the Liver.

Arch. Rönt. Ray, 1913, xviii, 48.

By Surg., Gynec. & Obst.

Except for the possible detection of biliary calculi, radioscopy is of more value than radiography in X-ray observation of the liver. The upper surface of the liver lying against the diaphragm can easily be seen; the lower edges are best seen when the hepatic flexure of the colon and the stomach are inflated with gas.

The author has been interested in noticing the mobility of the liver, particularly under different conditions of filling in surrounding hollow viscera. Changes in volume are seen in atrophies and hypertrophies and in certain heart lesions. Of particular

value are the changes in form and position of the upper liver or diaphragm shadow seen in liver abscess, subphrenic abscess, hydatid cyst, and occasionally in syphilis and cancer.

On account of their frequent transparency, biliary calculi are difficult or impossible to demonstrate in most cases. A careful radiographic technique is necessary.

HOLLIS E. POTTER.

Fischer, B.: Primary Chorio-Epithelioma of the Liver (Primäres Chorioepitheliom der Leber). *Frankf. Ztschr. f. Pathol.*, 1913, xii, 462.

By Zentralbl. f. d. ges. Gynäk. u. Geburtsh. s. d. Grenzgeb.

The author reports a primary chorio-epithelioma of the liver which macroscopically resembled a primary angio-epithelioma but microscopically showed an entirely different structure. The patient was a woman 35 years of age who, after her second pregnancy, became unable to work and "nervous." She was weak and suffered from nausea, dizziness, and lack of appetite and sleep. A year and a half later she was seized with severe gastric pains, icteric vomiting, cough, and hæmoptysis; subsequently icterus and fever developed. The liver was enlarged, palpable to the left costal arch, and painful. Severe anæmia was indicated by a hæmoglobin content in the blood of 45 per cent, nucleated red cells, polichromatophilia and poecilocytosis.

On section, the liver showed numerous soft, subcapsular, hæmorrhagic nodules the size of a hazel-nut. One of them was nearly as large as the fist. The vena cava and portal vein were not involved, but the hepatic vein and its branches showed numerous hæmorrhagic nodules protruding into the lumen similar to those found in the liver. In the head of the pancreas was a tumor the size of a walnut. The liver showed marked stasis and degeneration of the parenchyma. The tumor nodules consisted principally of clotted blood and thrombus-like stratified layers of blood and fibrin. On careful microscopical examination tumor cells were found (epithelial cells, giant cells, syncytii, great irregularity of cell structure, and giant nuclei). Without doubt, therefore, the case was one of typical chorio-epithelioma of Marchand's type. The pancreatic tumor was metastatic. As all of the other organs, including the uterus, were free from tumors, the chorio-epithelioma must have been primary. There are two possibilities as to its origin: it was due either to a primary teratoma of the liver with subsequent unilateral development of the chorio-epithelium or to an abnormal growth of chorionic villi, transported during pregnancy into the liver.

METTIN.

Chauffard, A.: A Large Amœbic Abscess of the Liver; Rapid Cure by Surgical Treatment Followed by Emetine (Grand abces amibien du foie. Guérison rapide par le traitement chirurgical suivi de la cure d'émétine). *Bull. et mem. Soc. méd. de hôp. de Par.*, 1913, No. 10, 630.

By Journal de Chirurgie.

Chauffard insists that emetine is of great value in treating amœbic abscesses of the liver, as it acts

as a specific to the parasite. He believes that it should be used in all cases of amœbic hepatitis. By treating amœbic dysentery with emetine from as near its beginning as possible, amœbic abscesses of the liver would become much less frequent. Further, the abscess may be stopped in its presuppurative stage as has been observed by Rogers. When pus has formed, Rogers advises emptying the abscess and injecting into it 6 to 10 cgr. of emetine in 30 to 40 cc. of water.

In a case of abscess of the liver, Chauffard opened the abscess by the transpleural incision used by Labey and evacuated some sterile, chocolate-colored pus containing amœbas. The fever fell immediately but at the end of seven days there was still a sanguine purulent discharge. At this time, 4 cgr. of emetine were injected subcutaneously. The next day 8 cgr. in 40 cc. of water were injected into the abscess cavity, and on the two following days, 4 cgr. of emetine were injected subcutaneously, making the total amount of emetine used equal to 20 gr. After the second injection there was no blood in the pus, and in six days the abscess had dried up.

Chauffard believes, however, that drainage of the abscess is necessary in addition to the use of emetine, if the cure is to be rapid. He feels that the value of the emetine treatment in reducing the mortality from, and the frequency of, amœbic abscesses of the liver will be inestimable. MAURICE CHEVASSU.

Kehr: Congenital Anomalies of the Gall-Bladder and the Hepatic Artery (Über angeborene Anomalien der Gallenblase und der Arteria hepatica). *Zentralbl. f. Chir.*, 1913, xl, 690.

By Zentralbl. f. d. ges. Chir. u. i. Grenzgeb.

On the basis of his own observations and of those reported in the more recent anatomical and surgical literature, Kehr has made a detailed compilation of the anomalies so far observed in the gall-bladder and the biliary ducts and vessels. Among those that are important from the surgical point of view are the absence of the gall-bladder and its misplacement either within the liver or on the left side of the body. Others are the anastomosis of the cystic duct with the hepatic duct at the bifurcation of the latter, a doubling of the hepatic duct, and numerous variations in the course of the hepatic and cystic arteries.

DENCKS.

Miyake, H.: Statistical, Clinical, and Chemical Studies of the Etiology of Gall-Stones, with Special Reference to Japanese and German Conditions (Statistische, klinische und chemische Studien zur Ätiologie der Gallensteine, mit besonderer Berücksichtigung der japanischen und deutschen Verhältnisse). *Arch. f. klin. Chir.*, 1913, ci, 54.

By Zentralbl. f. d. ges. Chir. u. i. Grenzgeb.

From the post-mortem material of the three large state universities of Japan the author has compiled the gall-stone findings in over 8000 sections. He reaches the conclusion that cholelithiasis is found in

3.05 per cent of the cases, less than one-half compared with statistics from Germany. The frequency of the affection in women as compared with men was as 3:2. Miyake believes that the German women are more predisposed to this trouble than the Japanese women because they wear corsets. He regards pregnancy as of minor etiological importance. In the Japanese, pigment stones are found most often, cholesterin stones more rarely. Intestinal parasites are a frequent cause of gall-stone disease in Japan. The rarity of cholesterin stones is a result of the national diet. In his investigation Miyake found colon bacilli or other bacilli mingled with the bile. These reached the gall-bladder probably by ascending infection from the intestine, or, much more rarely, by descending from the liver. An absence of hydrochloric acid in long-continued gall-stone disease was also noted quite frequently.

NORDMANN.

Frouin, A.: A New Technique for Establishing a Permanent Pancreatic Fistula; Presentation of Animals and Specimens (Nouvelle technique de la fistule pancréatique permanente; présentation d'animaux et de pièces). *Compt. rend. Soc. de Biol.*, 1913, lxxiv, 1283.

By Journal de Chirurgie.

The method most often used to establish a permanent pancreatic fistula is Pawlow's method which consists in transplanting to the skin the intestinal orifice of the duct of Wirsung after having made an incision in the duodenal wall which is later closed by sutures. According to Frouin, this method is open to criticism. The secretion of the flap of duodenum renders the pancreatic juice impure. Further, the pancreatic juice irritates the skin around the fistula and causes it to become bloody. As a result of this irritation the insertion of a funnel to collect the pancreatic juice causes pain which in turn sets up an inhibition of the pancreatic secretion. Moreover, the contractions of the abdominal wall compress the duct of Wirsung and interfere with its functioning.

The method used by Frouin overcomes most of these difficulties.

First he makes an incision 10 cm. long in the abdominal wall slightly to the right of the median line. Next he frees the duodenum and cuts the duct of Wirsung where it opens into the intestine. He then draws the duodenum up into the wound, and sutures it into the incision in the muscle, making a tampon. A stab wound is made in the skin above the duct of Wirsung; i. e., about 2 cm. from the incision. Often it is helpful in passing the duct to make also a transverse incision of 1 to 2 cm. in the muscles of the wall. The canal is placed in the groove and sutured to the skin.

In spite of the fact that there is some chance of duodenal occlusion and slow contraction of the orifice of the duct of Wirsung, this method keeps any spontaneous or reflex muscular contractions from exerting an effect upon the patency of the duct.

PIERRE CRUET.

SURGERY OF THE EXTREMITIES

DISEASES OF BONES, JOINTS, MUSCLES, ETC.
GENERAL CONDITIONS COMMONLY
FOUND IN THE EXTREMITIES

Mintz, W. M.: The Osgood-Schlatter Disease
(Über die Osgood-Schlattersche Krankheit). *Verhandl. d. Russ. chir. Kong.*, 1913, xii, 201.
By Zentralbl. f. d. ges. Chir. u. i. Grenzgeb.

Mintz discusses the nature of the localized bone disease that occurs in the tuberositas ossi tibiae. This condition is found usually in young males of from 12 to 17 years of age, and it is the right tibia that is most frequently involved. The author disagrees with the theory of Schlatter that it is due to a tearing off of the tuberosity, for the callus, which according to that theory would form at the site of the porous bony bridge, in reality is much lower and just at the end of the tuberosity. The author doubts that this connecting bridge of the upper and lower ossification center is a locus minoris resistentiae as it lies in a thick layer of cartilage and is protected against fracture. The true nature of the disease can be determined by operative procedure and subsequent microscopical examination. Mintz operated in two of his four cases.

Neither of these cases had ever had any trauma. The first was that of a young man 16 years of age. At the operation a wedge-shaped excision of the diseased focus was made. Complete cure resulted. On macroscopical examination of the diseased part, a marked hyperemia was noted. Microscopical examination showed new formation of bone, rarefaction, and osteoclasia. The second case was that of a boy 15 years of age. For two years the patient had had a painful swelling over the site of the tuberosity of the tibia. He walked with difficulty. Excision was performed. The excised part consisted of cartilaginous and bony tissue and osteoid masses.

All four observations, according to Mintz, disprove Schlatter's fracture theory. Radiographical and microscopical examinations revealed both progressive and retrogressive bone changes. This atypical bone formation is induced by some unknown cause. With the cessation of the growth of the bone the disease stops. Similar processes occur also in other epiphyses, especially in the epiphysis of the fifth metatarsal bone (Iselin), in the olecranon, and in epiphyses to which tendons are attached.

HESSE.

Marie, P., and Leri, A.: Paget's Bone Disease
(Die Pagetsche Knochenkrankheit). *Handb. f. Neurol.*, 1913, iv, 471.

By Zentralbl. f. d. ges. Chir. u. i. Grenzgeb.

Paget's bone disease is relatively rare, only about 100 cases of it having been described to date. It is a chronic, progressive, and systematic osteopathy which may affect the entire skeleton. Usually,

however, it is confined to certain flat bones and the diaphysis of certain long bones in which it produces hypertrophy and deformation. After a short historical sketch and a few hints as to the etiology, the authors discuss the symptoms. Pain may be entirely absent, but if it does occur it is noted at the beginning of the disease and gradually decreases at the height of it. Usually the tibia is affected most. The Paget skull is the shape of a triangle with the base upward. The forehead and parietal bones protrude as in the hydrocephalic head. The base is particularly deformed, being at times almost a true convexobasis. The authors describe in detail also the condition of the other parts of the skeleton. The X-ray examination shows a complete change in the trabecular structure, a "cotton"-like appearance of the diaphysis and the epiphyses. In the discussion of the differential diagnosis especial mention is made of Marie's pseudo-Paget's disease or senile osteoporosis in which there is no hypertrophy of the bones. In Paget's disease the bones are thick, their volume often being double the normal. They break easily, however, as they are exceedingly porous. According to the findings of microscopical examination rarification in general predominates over condensation.

The author's conclusions in regard to the pathogenesis of Paget's disease are as follows: "All of the theories promulgated by different observers may be true in part. Paget's bone disease, hypertrophic bony sclerosis, may be the result of nutritional disturbances referable to arterial lesions. These arterial lesions themselves may be of different origins. Generally they are due to calcification of the arteries; sometimes to syphilitic arteritis, and sometimes to an arteritis caused by hyperacidity of the blood resulting from an accumulation of mineral acids or the incomplete neutralization of decomposition products. More frequently they may be traumatic arterial lesions or those caused by inflammatory, traumatic, or degenerative processes in the trophic or vasomotor nerves." The treatment, according to the authors, should consist primarily in symptomatic and palliative measures.

HESSE.

Ely, L. W.: Diseases of Joints and Bone Marrow.
Am. J. Surg., 1913, xxvii, 249.

By Surg., Gynec. & Obst.

Joint diseases are divisible into two main classes: (1) proliferation of synovia and marrow, with resulting atrophy of cartilage and bone; and (2) inflammation of synovia and marrow with resulting hypertrophy of cartilage and bone. All joint diseases are probably infectious. Type I includes tuberculosis, chronic gonorrheal and syphilitic arthritis, and rheumatoid arthritis, also called atrophic arthritis, proliferative arthritis, and metabolic osteo-arthritis.

Joint tuberculosis. Too much reliance must not be placed on experimental work. Injection of a tubercle bacillus culture into a joint cavity causes a reversed pathological course. Tuberculosis attacks the epiphysis and not the shaft because of its marked affinity for lymphoid tissue.

The tuberculous process is limited by the cartilage, the periosteum, and the shaft. If it goes beyond the cartilage it does so by extending around it or penetrating through it after having caused degeneration of that tissue by cutting off its nutrition. When the synovia is infected the original tubercle is found in its lymphoid tissue. Apparent enlargement at the joint is due to atrophy of the muscle.

The symptoms include pain, stiffness, swelling, limitation of motion, change in attitude, deformity, disturbance of function, local rise in temperature, bone involvement, muscular spasm, and muscular atrophy. Purely synovial cases are distinctly mild and may elude diagnosis. Abscesses are very frequently formed.

Complications: Phthisis, adenitis, meningitis in children, and amyloid degeneration after prolonged suppuration.

The prognosis for life is good for children. Functional results vary with age. "Painless motion in an adult tuberculous joint is an iridescent dream." Children may recover with good function.

Diagnosis. Tuberculosis may be differentiated from other diseases in Type I by its slow, steady course and uniarticular nature; from those of Type II, by the presence of active inflammation and absence of exostoses.

Local treatment: (1) deprive the joint of function; (2) avoid secondary infection. In general, conservative treatment in children, radical treatment in the adult. Conservative treatment should prevent deformity and deprive the joint of function. It is essential that treatment by apparatus be continued without interruption.

Tuberculin treatment is not of value. Bier's hyperæmic treatment is "worth a trial." Injection of substances into the joint may be harmful.

Radical treatment consists in the destruction of function. Finger and toe joints should be treated by amputation. In the spine, where resection is impracticable, an Albee bone splint should be applied.

Chronic gonorrhœal arthritis. The absence of bony outgrowths (usually), the appearance in the Röntgen plate of the joint itself, and the history place this disease in Type I. Treatment: Set the genito-urinary tract in order; mobilize the joint, under anæsthetic if necessary.

Joint syphilis. There are two forms of joint syphilis, one of which corresponds to the synovial form of tuberculosis and the other to the osseous type. Another form, more frequent, is a proliferative inflammation of the marrow and periosteum of the bone end. Mobilization is useless. Mercury has been our "sheet anchor." Some cases yield to one or two doses of salvarsan after a course of mercury.

The etiology of other diseases of Type I is uncertain. It would be wise to study the bone marrow, the active tissue, in seeking the cause of affection of the passive tissue.

W. A. CLARK.

Bankart, A. S. B.: The Pathology and Treatment of Hallux Valgus. *Med. Press & Circ.*, 1913, xcvi, 33.
By Surg., Gynec. & Obst.

The part played by shoes in the etiology of hallux valgus has been exaggerated. In the majority of cases the deformity is due to flat-foot, and results from tension on the tendons of the great toe caused by the elongation of the skeleton of the foot. The deviation is outward because of the predominance of muscle attachments on the outer side of the toe.

Treatment: The entire head of the metatarsal bone should not be resected, as such resection destroys the anterior support of the arch. Instead, the tendons of the extensor and flexor longus hallucis should be divided, the prominent part of the bone chiseled away, the toe forcibly abducted, and the capsule sewed back to the head of the metatarsal bone. Treatment for the accompanying flat-foot must also be carried out.

W. A. CLARK.

Schwarz, A.: The Etiology of the Bursitides (Zur Ätiologie der Bursitiden). *Wien. med. Wchnschr.*, 1913, lxiii, 1854.

By Zentralbl. f. d. ges. Chir. u. i. Grenzgeb.

Inflammation of the bursæ at different joints is not due to traumatism alone. Infections and nutritional disturbances due to diseases of metabolism also are primary or secondary causes of the pathological changes. After an attack of angina or tonsillitis the bursæ of the different joints are frequently painful to pressure. This condition gradually improves with the improvement in the primary disease. Micro-organisms may enter a bursa with the blood stream and remain there latent even after the acute infection has ceased, and these, after a second infection or trauma, may lead to atrophy or shriveling of the bursa. A predisposition to rheumatism or gout, gonorrhœa, lues, etc., may also be the cause of the disease. Accurate knowledge of the etiological factors as well as of the anatomical location of the individual bursæ is important, for if the affection is recognized early, errors in treatment will be avoided and stiffening of the joints prevented. Local applications of mud, or better, hot air treatment, energetic massage, and early mechanotherapy usually render good results.

DE AHNA.

Fenwick, W. S.: The Conservative Treatment of Tuberculosis of Joints. *Brit. M. J.*, 1913, ii, 109.
By Surg., Gynec. & Obst.

Fenwick admits the advisability of radical operation in certain adults. Considering some of the dangers of the radical operative procedures in children, he believes that there is the danger of general tuberculosis and tuberculous meningitis. He quotes

the statistics of H. J. Stiles to emphasize this, and says that while radical operations may be usually performed in the more severe cases, he still feels that even better results would be obtained by the conservative treatment in children in the same class of cases. The radical operation is objected to also because it causes considerable shortening. Under treatment, Fenwick advises the use of cod-liver oil and phosphorus and proper feeding, which is very essential in the class of cases at Queen's Hospital, for the children are drawn from the crowded districts of London. The ordinary methods are employed to reduce deformity, and fixation is established by splints. Periodic examinations by X-ray are insisted upon. Bier's hyperæmia is employed as a routine. Iodoform injections are used on the more resistant cases. Abscesses are tapped and injected with iodoform emulsion. Cases resisting this line of treatment are operated on and arthrectomy or erosion is the choice. The author states that he has never amputated in children. He is a strong advocate of the use of tuberculin and advises its use preparatory to operating on any case of tuberculosis. He administers tuberculin either hypodermically or by mouth.

M. S. HENDERSON.

Ehrlich, H., and Maresch, M.: Gangrene of the Extremities and Its Treatment (Über Gangrän der Extremitäten und ihre Behandlung). *Wien. klin. Wchnschr.*, 1913, xxvi, 1058.

By Zentralbl. f. d. ges. Chir. u. i. Grenzgeb.

During the last twelve years eighty-one cases of gangrene of the extremities were treated at von Eiselsberg's clinic. Of these, one was caused by electric current, two by embolism, two by freezing, three by ligature of the popliteal artery, forty-four by arteriosclerosis, and twenty-nine by diabetes. The conclusions drawn from this material are as follows: Unless septic processes necessitate earlier operative procedure, the treatment in all forms of gangrene which are not caused by diffuse or progressive diseases of the arterial system should be expectant until there is a demarcation such as in cases of injuries, burns, freezing, etc., in the juvenile. In arteriosclerosis, if the general conditions be favorable, the phalanges should be allowed to separate spontaneously. Exarticulations in the area of the foot are not warranted because they offer but small chance for a permanent cure. In cases where there is an insufficient demarcation, a progressive process, infection complications, or unbearable pains, only amputation can be considered. In senile gangrene the operation should be performed at the thigh. In presenile gangrene good results may be obtained by amputating the lower leg, provided that the extension of the process offers no contra-indication, the pulse is distinctly palpable at least in the poplitea, and the amputated stump bleeds freely during the operation. The only operation on the lower extremities of diabetic patients that is warranted is amputation of the femur.

REHN.

FRACTURES AND DISLOCATIONS

Binney: Report of Eighteen Cases of Separation of the Lower Femoral Epiphysis at the Boston City Hospital. *Boston M. & S. J.*, 1913, clxix, 49.

By Surg., Gynec. & Obst.

The author first takes up briefly the history of the treatment of separation of the femoral epiphysis, contrasting the former mortality and poor results with the present day favorable outcome.

The etiology as quoted from Scudder, Stimpson, and Cotton is hyperextension. The pathology varies with the nature of the injury, Scudder stating that it is compound in 50 per cent. The lesion may be a simple loosening of the epiphysis with slight displacement, and there may be great shifting of the fragments forward and upward in front of the lower end of the shaft, with extensive tearing of the periosteum. The popliteal vessels and nerves may be tightly drawn over the end of the diaphysis like the strings over the bridge of a violin, causing gangrene from arterial thrombosis. The nerve injury is usually to the external popliteal, a number of cases being followed by some degree of toe-drop. As a rule, the edge of the diaphysis presents in the wound.

The author next discusses the mechanical factors affecting displacement, depending upon the attachment of the gastrocnemius quadriceps and popliteus muscles.

Symptoms and diagnosis: Any case of injury to the knee in a patient below twenty years of age is suggestive of epiphyseal separation. The classical factors of these lesions are marked prominence in the region of the patella, with a transverse depression across the thigh just above the patella and the bony prominence in the popliteal space. Mobility just above the knee-joint and a soft crepitus, if present, are suggestive. Pulsation in the vessels of the leg may be wanting with the accompanying pallor and swelling of the extremity. With any considerable amount of displacement there will be shortening of the limb.

The diagnosis from dislocations of the knee is usually easy. In fractures of the lower end of the femur, the bony crepitus and character of the deformity should give evidence by which the differentiation can be made. In many cases, however, the X-ray is the only method by which diagnosis can be made.

The author next lays great stress on the X-ray examination both before and after reduction because of the marked tendency of the lower fragments to assume a malposition.

The danger of some degree of arrest in growth of bone must always be considered. The introduction of a foreign body, such as a nail, screw, or wire, seems to increase the danger of disturbance of growth. Immediate reduction and placing of the divided cartilage in position favorable for growth is of great importance. Also immediate treatment is indicated to relieve pressure on the nerves and vessels.

In simple separation without extensive detachment of the soft parts, fixation in the extended or slightly flexed position is sufficient. In the majority of cases an anæsthetic is necessary. An X-ray examination must be made to insure the maintenance of the correct position. Fixation in acute flexion sometimes helps when other methods fail. When the reduction can not be accomplished by these methods, immediate operation should be done. With evidence of injury to the vessels, acute flexion should not be employed, on account of the obstruction to the circulation.

Compound fractures are treated by thoroughly cleansing the wound; the displacement having been reduced, fixation of the fragment must be secured. Excision of the joint is probably never necessary when easy reduction is obtained.

Conclusions: 1. Owing to danger of subsequent interference with growth, absolute reduction and fixation at the earliest moment is of great importance.

2. Early and repeated X-rays are necessary to control the completeness and permanency of the reduction.

3. In simple cases where immobilization in flexion fails to hold the fragment in correct position from the start, open reduction with the use of a small nail or bone-plate is indicated.

4. In compound separation the same means of positive fixation is to be recommended.

5. The foreign body should be removed soon after union has begun in order to avoid interference with growth. This should be done not later than the third week.

FREDERICK G. DYAS.

Jones, R., and Smith, S. A.: Rupture of the Crucial Ligaments of the Knee and Fractures of the Spine of the Tibia. *Brit. J. Surg.*, 1913, i, 70.

By Surg., Gynec. & Obst.

The X-ray has shown that fracture of the spine of the tibia, often associated with rupture of one or the other of the crucial ligaments, is much more common than is generally supposed.

An investigation by the authors has shown that rupture of one or of both of the crucial ligaments occurs frequently in dislocation of the knee joint.

The authors quote Hogarth Pringle's paper, published in 1907, as the first article to treat of rupture of the crucial ligaments with avulsion of the spine of the tibia. They then describe the anatomy of the articular surface of the knee joint in detail, emphasizing the following facts:

(1) That the anterior crucial ligament is tense when the knee is fully extended, and prevents the tibia from being displaced towards the femur.

(2) That the posterior crucial ligament is tense in complete flexion, and prevents the tibia from being displaced backwards on the femur.

(3) That both ligaments check inward rotation of the tibia.

Hence if after an injury to the knee, the tibia can be displaced backwards and forwards or rotated

inwards in the extended position, injury of one or both crucial ligaments may be diagnosed. The most constant sign of fracture of the spine of the tibia is an obstruction to full extension. FREDERICK G. DYAS.

SURGERY OF THE BONES, JOINTS, ETC.

Gask, G. E.: Autoplastic Graft of Fibula into Humerus after Resection for Chondrosarcoma, with Observations on Bone-grafting. *Brit. J. Surg.*, 1913, i, 49.

By Surg., Gynec. & Obst.

The author first gives briefly a review of the various methods of grafting bone and other tissues that have been in use during the last twenty-five years. He then reports a case of tumor of the humerus, which necessitated the removal of a portion of the shaft three inches long and the implantation of a portion of the fibula from the same patient. The union was good and resulted in complete use of the arm. Measurements showed that the humerus after the operation was three-eighths of an inch shorter, and the circumference of the limb, one-quarter of an inch less than normal. The loss in the fibula was not appreciable. The patient can walk as well as ever and is not weak on the operated side.

Technique: The portion of the humerus affected was removed, together with its periosteum, and the graft of the fibula was inserted with its periosteum intact. No holes were drilled into the graft. All muscular and tendinous attachments of the fibula were carefully dissected off. The bones were not secured in position by any foreign body, such as a screw, peg, or plate.

Conclusions: (1) An autograft of bone under favorable conditions (youth of the individual is a favorable factor) will live and grow. It will certainly grow in thickness, though whether it will grow in length and at the same pace as the corresponding bone of the opposite arm, remains to be proved.

(2) The periosteum of the graft is of service to the bone, both as a limiting membrane and as an active factor in the deposition of new bone.

(3) There is evidence to show that bone will grow without its periosteum and that even marrow alone will survive and deposit new bone. However, until we know more, it is better, when possible, to employ bone that is covered with its periosteum.

(4) Transplantation of the bone from an animal to man, and the use of bone from dead bodies, is merely in the experimental stage. FREDERICK G. DYAS.

Klopfer, E.: Free Transplantation of Fat into Bone Sinuses (Über freie Fetttransplantation in Knochenhöhlen). *Beitr. z. klin. Chir.*, 1913, lxxxiv, 499.

By Zentralbl. f. d. ges. Chir. u. i. Grenzgeb.

The clinical experience in seven cases was very encouraging, and shows that filling the cavity with living tissue is superior to any method in use at present. The procedure is worthy of recommendation for aseptic as well as infected cases. REHN.

König: Successful Plastic Operation on the Elbow-Joint by Means of Implantation of an Ivory Prothesis (Erfolgreiche Gelenkplastik am Ellbogen durch Implantation einer Elfenbeinprothese). *München. med. Wchnschr.*, 1913, lx, 1136.
By Zentralbl. f. d. ges. Chir. u. i. Grenzgeb.

On the strength of a successfully treated case of ivory transplantation into the elbow-joint, König again calls attention to the possibility of utilizing ivory in plastic operations on bones, and particularly emphasizes the simplicity of the procedure.

The patient, a healthy girl, had a spindle-cell sarcoma of the median condyle of the humerus. At the operation almost the entire distal portion of the humerus was removed; only the capitulum and humeri remained. Into the resulting defect an exact ivory substitute previously prepared was inserted and held by two ivory pegs. A few weeks later a plastic operation on the muscles became necessary. The end result was good. The patient has had no recurrence in over a year; has a joint movable over more than one-half of a right angle, and firm in every respect. Extension is possible to 135° , flexion to 85° , and rotation is complete. VON TAPPEINER.

Von Saar, G. F., and Schwamberger, R.: The Ulnar Longitudinal Incision for Operations in the Region of the Volar Surface of the Wrist Joint and of the Hollow of the Hand (Der ulnare Längsschnitt, eine Schnittführung für Operationen im Bereich der Volarfläche des Handgelenks und der Hohlhand). *Zentralbl. f. Chir.*, 1913, xl, 993. By Zentralbl. f. d. ges. Chir. u. i. Grenzgeb.

In order to avoid unnecessary secondary injuries and to permit a good exposure of the operative field, the authors have designed an incision in the region of the volar surface of the wrist joint, which they illustrate with drawings. The incision is made in the middle of the space between the flexor carpi ulnaris and the palmaris longus in such a direction that it will strike the narrowest point of the anterior annular ligament. HARF.

Osgood: The End Results of Excision of the Knee for Tuberculosis with and without the Use of Bone Plates. *Boston M. & S. J.*, 1913, clxix, 123.
By Surg., Gynec. & Obst.

The author first discusses the various methods of excision of the knee joint with their modifications, and outlines the method which he advocates as follows: A two- to four-day preparation is given to the knee joint which has preferably been previously fixed in plaster for at least one month. The field is prepared by a benzine-iodine skin preparation and an Esmarch bandage is applied. A U-shaped incision is made extending from the inner femoral condyle downward across the patellar tendon, an inch above the tubercle, and upward to above the outer femoral condyle. Before the skin is cut through, three tiny scratches are made, one at the lower limit of the incision and one on either side, to facilitate accurate skin reposition. The incision is then carried down to the bone, dividing the patellar

tendon. The edges of the wound are swabbed with tincture of iodine. The proximal end of the patellar tendon is seized with double hooks, and the flap, containing skin, fat, patella, diseased tissue and upper cul-de-sac is quickly dissected back, the knee being gently flexed. Much of the tuberculous tissue is removed as the lower end of the femur and upper end of the tibia are isolated. A quick dissection of the upper cul-de-sac is made.

Estimating the desired angle of fixation, the lower end of the femur is sawed off with a flat saw just above the diseased tissue. The upper end of the tibia is next sawed off and a quick dissection of the tissue in the posterior capsule is made. The patella is removed, or its under surface sawed off.

It has been the custom for the last four years, in the absence of a sinus or of a mixed infection, to fix the ends of the bone by means of malleable iron plates, or aluminum wire clamps, one on either side and one in the middle. The patellar tendon is then sutured, the skin flap is replaced, and the leg put up in plaster of Paris.

Fourteen simple excisions had a second operation for re-excision. These cases were secondarily infected. Four had sinuses before the operation, and nine after. Pain persisted several months after the operation in five cases. Eventual union occurred in six. The time of union was two months or less in two, three months or more in eleven; there is no record of eventual union in five.

Comparing these cases with those in which plates or clamps were used, none came to operation for re-excision. One amputation was done outside the hospital. Two had sinuses before operation, and five after. Pain persisted several months only in the amputated case. Eventual union occurred in thirteen. The time of apparent firm union was one month or less in six cases, two months or less in four, three months or more in three.

Conclusion: Comparative statistics of this small series seem to show that the holding of the nicely approximated bone ends firmly together has definite advantages. Post-operative pain is less; early union is favored; the only untoward effect is the occasional removal of the plate. A table of statistics is appended.

FREDERICK G. DYAS.

Schepelmann, E.: Free Transplantation of Periosteum (Freie Periosverflanzung). *Arch. f. klin. Chir.*, 1913, ci, 499.

By Zentralbl. f. d. ges. Chir. u. i. Grenzgeb.

In a series of earlier experiments the author attempted by transplantation to repair a defect of the trachea with periosteum wound around a piece of glass tubing. Recently he has investigated the conditions which determine whether transplanted periosteum will form new bone. He agrees with other investigators that under favorable conditions it is possible in all tissues to obtain periosteal bone formation in transplanted periosteum. Success is assured more often, however, when the tissues into which the transplant is placed are very vascular and

parenchymatous. The results are so uncertain, however, that it is doubtful whether the procedure will ever be of much practical value. The conditions which determine success to a considerable extent are: autoplasty in preference to homoplasty, the age of the patient, the vascularity of the area into which the periosteum has been transplanted, the integrity of the cells, the permanent union between the underlying layers and the periosteal membrane, and the immediate transplantation of the periosteum, after its removal, into its new bed. The influence of functional stimulus on the formation of bone in periosteal transplants has yet to be determined by further investigations. HELLER.

Petrasczewska: A Case of Free Transplantation of Half a Joint (Ein Fall von freier Transplantation eines halben Gelenks). *Verhandl. d. wiss. Ver. d. Ärzte d. städt. Obuchow-Krankenh.* St. Petersburg, 1913, xxii, 41.

By Zentralbl. f. d. ges. Chir. u. i. Grenzgeb.

The author removed the entire fifth metacarpal bone for sarcoma. He replaced the bone with the fifth metatarsal bone, which was sawed off at its base. The joint end (distal end) was placed into the first phalangeal joint and the sawed end was placed against the os hamatum. Primary union resulted. The function of the newly formed joint is identical with the sound joint on the other hand. The defect in the foot caused no disturbance.

O. VON SCHILLING.

ORTHOPEDICS IN GENERAL

Young, J. K.: Practical Progress in Orthopedic Surgery. *Del. St. M. J.*, 1913, iv, 1.

By Surg., Gynec. & Obst.

The scope of orthopedic surgery includes deformities dependent upon (1) lesions of the bone; (2) lesions of the cerebro-spinal system; (3) impaired nutrition; (4) disturbances of development; and (5) traumatism.

Arthritis deformans. Formerly called "rheumatic gout." From 50 to 80 per cent of the cases are females. The etiology includes trauma, neurotic conditions, pathogenic bacteria, and toxæmias. Still's disease in children is similar but includes more constitutional symptoms.

Serum therapy. The most suitable cases for bacteria treatment are those showing symptoms of toxic absorption but no true septicæmia.

Psoas abscess. Early operation is advised for mixed infection. The incision is made two and one-half inches from the spinous process, midway between the last rib and the crest of the ilium.

Lateral curvature. The most recent and prominent advance in the treatment of lateral curvature is the Abbott method of correction which consists in placing the patient in a specially constructed frame, and, by means of canvas bands, twisting him into corrected position. A heavy plaster cast is then

applied and padding is used to force the body to the concave side. The treatment covers a period of from six to twelve weeks.

Infantile spinal palsy. The greatest advance is in tendon transplantation. Most orthopedic surgeons prefer periosteal implantation.

Sacro-iliac displacement. Goldthwaite's work has revealed frequent ankylosis between the last lumbar vertebra and the sacro-iliac articulation. The displacement may be of the traumatic or of the static variety.

The static variety is composed largely of the neurotic and the uterine types. The symptomatology includes pain, limitation of motion, abnormal mobility, and changes in attitude.

Cerebral palsy. Tendon lengthening and transplantation are of great value, but mental training is also of much importance.

Torticollis. The best age for operation is between six and twelve. The sterno-cleido-mastoid should be divided at the clavicle and the head fixed in an over-corrected position for three weeks.

W. A. CLARK.

Washburne, C. L.: A Study of Congenital Dislocation of the Hip with Report of Six Cases. *Physician & Surg.*, 1913, xxxv, 306.

By Surg., Gynec. & Obst.

Congenital dislocation of the hip was recognized by Hippocrates. Pravacz in 1838 was able to reduce the deformity but could not fixate to prevent recurrence. Lorenz in 1902 popularized the bloodless method. Etiological theories: (1) anomaly in development, (2) intra-uterine pressure. The latter is the more attractive theory. The position of flexion-adduction assumed by the fetal legs is the position in which the minimum areas of joint surfaces are in contact and which, if prolonged and under pressure, is most favorable to a permanent displacement of the head out of the acetabulum. The greater frequency of congenital dislocation of the hip in females is probably due to the fact that in the wider pelvis the acetabulum is in a more posterior-lateral position. The author reports six cases and concludes from his experience that, as a rule, adductor tenotomy is bad practice, that the wedge fulcrum is a dangerous instrument, that the most favorable time for reduction is between the ages of three and ten, and that in patients over ten years open operation is advisable.

W. A. CLARK.

Carr, W. P.: An Operation for Flat-Foot. *Am. J. Surg.*, 1913, xxvii, 270. By Surg., Gynec. & Obst.

In reporting a case of traumatic flat-foot, cured by an unusual operation, Carr says:

"Sawing through the os calcis, between the ankle joint and the attachment of the tendo achillis, slipping the sawn portion of the bone downward three fourths of an inch, and nailing it there, is an operation not difficult nor dangerous."

This relatively simple procedure was carried out by Carr on an electrician 37 years of age. The saw-

ing was easily accomplished with a modified Wyeth saw. The wounds healed promptly, and in six weeks the patient was able to walk better than before the operation. He has continued to improve. The

author recommends this procedure in cases of flat-foot caused by injury and those which are not improved by the ordinary methods of treatment.

PAUL P. SWETT.

SURGERY OF THE SPINAL COLUMN AND CORD

Kleinberg, S.: Abbott Treatment of Rotary Lateral Curvature of the Spine and Details of the Technique. *Surg., Gynec. & Obst.*, 1913, xvii, 32.
By Surg., Gynec. & Obst.

The Abbott method of treating rotary lateral curvature of the spine depends on the theory that the spine is influenced in its motions to the greatest degree when it is relaxed. It is relaxed in the flexed position. Hence the patient is placed for treatment in a hammock suspended in a rectangular frame. The frame has several bars on each side for the attachment of "fixing" and "corrective" bands. The shoulder and hip girdles are fixed and correction is obtained by two bands, made preferably of canvas, which go over the chest and are attached on the side opposite the deformity in such manner that one band pulls sideways and the other backwards, thus tending to correct rotation and lateral deviation. A plaster of Paris jacket is then applied and four windows excised: a very large window over the concavity behind; one over the sternum; one a little outside of the deformity; and one in the axilla on the side of the deformity. Thick felt is used for correction padding. The pads are inserted through the anterior window to correct the rotation, and through the two windows on the side of the deformity to correct the deviation. They are inserted as often as the patient's tolerance and general condition will permit and when the maximum correction in any particular jacket has been attained, a new jacket is applied. The wearers of the Abbott jacket suffer at times a great deal of inconvenience, pain, dyspnoea and weakness. Tachycardia, prostration and other evidences of shock must be guarded against.

Perhaps the best method of judging what correction has been attained is the use of the X-ray, the picture being taken when the patient is outside of the plaster jacket. Thirty-one cases were treated in this manner. Of these, ten gave it up because of the inconvenience and discomfort. Three cases, which were high cervico-dorsal deformities, were given up because no improvement had been obtained. Of the rest, four were over-corrected and the remainder improved in varying degrees.

In conclusion, the author states that the Abbott method is severe; many cases can be corrected by it, especially the milder ones, but the correction is so slow that the treatment must be prolonged.

McGlannan, A.: Ankylosis of the Spine. *J. Alumni Ass. Coll. Physicians & Surg., Balt.*, 1913, xvi, 47.
By Surg., Gynec. & Obst.

There are three varieties of spinal ankylosis. The first is due to inflammatory new bone (spondylitis

deformans). It may be caused by pyogenic bacteria or by trauma. The ossification is beaded along the ligaments and thicker at the discs than at the bodies. The patients are almost always past middle life. The second variety is a "bony metamorphosis of spinal ligaments," fiber by fiber, with no irregular projections (spondylose rhizomelique). The ossification is an adaptive process to supply rigidity following a primary softening of the bone. Proof of this purposeful change is the fact that the position of the ossification is advantageous for resisting the strain. This type of spinal ankylosis usually occurs in young adults. The third type is a repair process such as follows tuberculosis and fractures.

Treatment: Remove the active or dormant source of infection. In cases of spondylose rhizomelique fix by traction.

W. A. CLARK.

Alldrich, H. C.: Bone Transplantation as a Treatment of Pott's Disease. *J. Am. Inst. Homeop.*, 1913, vi, 28.
By Surg., Gynec. & Obst.

The article is a good review of the Albee method of producing bony fixation in tuberculosis of the spine. Nothing new is contributed to the subject. The author reports one recent case with good result and recommends the procedure.

G. I. BAUMAN.

Castelli, E.: Methods of Localization of Spinal Tumors with Reference to Their Medical and Surgical Treatment. *Med. Rec.*, 1913, lxxxiv, 1.
By Surg., Gynec. & Obst.

The author does not classify tumors according to their origin but divides them into (1) extramedullary and (2) intramedullary tumors.

Little is known as to the etiology of the extramedullary tumors. There are several varieties of these, among which are fibroma, angiosarcoma and neurofibrosarcoma. Of the intramedullary, the most common varieties are glioma, tubercle, fibroma, neurofibroma, and fibrosarcoma.

The pathological conditions in the region of these tumors vary greatly according to the class to which the tumors belong. In the case of the intramedullary tumors, the destruction of the tissues of the cord is often very marked and the cord structures may be greatly displaced and thinned out. In the case of the extramedullary tumors, the destructive changes are rare and appear only after the lapse of years.

The symptoms of these conditions resemble the symptoms of compression of the cord. Both have a slow evolution but it is usually possible to distinguish between those of the extramedullary type of tumors and those of the intramedullary type.

In cases of extramedullary tumor, pain is a very constant symptom and is usually the first to appear. The pain is of an aching type, and of remarkable localization, usually in the posterior lateral aspect of the thorax. It is constant and neuralgic and is often increased by effort such as deep breathing or sneezing. Accompanying the pain, but usually appearing later, are areas of painful hypoesthesia and anesthesia. This stage is called the nerve-root phase. Later, atrophy of muscles can be noticed, weakness in the lower limbs, sometimes in all the limbs, follows, and a progressive paraplegia develops. The characteristic feature of the paraplegia is, that while the paralysis is mild, the contractures are very marked. Involuntary movements of defense are often caused spontaneously but may be elicited by a very slight cutaneous stimulation. They consist of dorsal flexion of the foot on the leg, flexion of the leg on the thigh, and of the thigh on the pelvis. Usually the Babinski sign is elicited at the same time. It is very important to determine the exact upper limit at which this reaction of defense can be elicited as it marks the lower limit of the tumor. The cutaneous reflexes are usually abolished at the upper level of the tumor and from this level downward. Therefore, by determining these two zones, the upper limit of the reflex of defense and the upper limit of abolishment of the cutaneous reflexes, the lower and upper limit of an extramedullary tumor can be determined.

In the case of the intramedullary tumor, pain is a rare symptom and is late in appearance. Paraplegia appears early, evolves rapidly, and is usually accompanied by a Brown-Séquard syndrome. The paralysis is real, and although there may often be contractures, they do not predominate over the paralysis. Sensibility is early affected. The superficial sensibility is affected more decidedly on the side opposite the paralysis, the deep sensibility on the same side as the paralysis (real Brown-Séquard). The tendinous reflexes below the compression are exaggerated as in the case of extramedullary tumor.

When the symptoms described above are reviewed, it will be seen that there are many differences between those of the two kinds of tumor. The Wassermann reaction of the spinal fluid may sometimes be misleading as to the etiology of the condition.

Treatment in the case of extramedullary tumor should be surgical, and if the tumor can be reached and removed the prognosis is good. In the case of intramedullary tumor, the consensus of opinion is that there should be no intervention. In rare instances, however, an operation can be performed in two steps as follows: (1) splitting the dura mater over the region of the tumor and (2) removal of the tumor if it has presented itself in the period intervening between operations. The prognosis is grave, however, and intramedullary tumors are apt to recur.

J. H. SKILES.

SURGERY OF THE NERVOUS SYSTEM

Biesalski, K.: The Spastic Paralysis of Childhood and Its Treatment (Die spastische Lähmung im Kindesalter und ihre Behandlung). *Deutsche med. Wchnschr.*, 1913, xxxix, 699.

By Zentralbl. f. d. ges. Chir. u. i. Grenzgeb.

This study presents the present state of our knowledge in regard to spastic paralysis. The clinical course of the disease is described with special reference to the paralysis, the spasms, and the involuntary motion. Considerable importance is attached to the paralysis, since recently much more has been said of the hypertonus of the contracting muscles than about the motor weakness of their antagonists. It is decidedly more difficult to treat the latter than to weaken the excessive strength of the spastic muscles. The spasms are caused principally by multiple stimuli which travel from the periphery to the center, where, not being controlled by the higher regulating centers, they manifest themselves as involuntary reflex movements. One of the complications receiving special mention is the spastic dislocation of the hip-joint, which has recently been noted in several cases of spastic paralysis. This association may throw some light on the mechanism of the luxation.

Exercise is the most important factor in the treatment as it only can restore co-ordination. Operative

procedures are limited to those that restore proper relations between the component parts of a limb and those that overcome the existing conditions between the single muscle groups by means of tendoplasty and the lengthening of the tendons. In very serious cases Förster's operation of resecting the posterior roots gives good results. It decreases the peripheral sensitiveness and thereby lessens the motor impulses. On the periphery, Spitzzy's neuroplasty and Stöffel's partial neurectomy may be used. The former seeks to raise the motor power of the hypotonic nerve and muscle area by anastomosing to them the partially resected nerve out of the hypertonic area. The latter decreases the motor energy of the hypertonic muscles by resecting the single nerve-branches leading to the muscles. All operations, however, must be followed by careful after-treatment in the way of exercises. Good results can be expected only when the operative interference is regarded as merely the first step toward successful treatment. SPITZY.

Harris: The End Results of Operative Treatment in Thirty-Three Cases of Spastic Paralysis. *Boston M. & S. J.*, 1913, clxix, 82.

By Surg., Gynec. & Obst.

In the five years ending in 1912, there have been operated at the Children's Hospital, Boston, 57

patients with spastic paralysis. The investigation was limited to 33 that could be traced, and of this number 22 were seen at home or in the out-patient department. They comprised 12 paraplegias, 5 hemiplegias, 4 diplegias, and 1 monoplegia. From observations of the results of the operative treatment the author concludes that excellent results in these cases have followed subcutaneous tenotomies, and this has an important bearing on the question as to whether there is danger of permanent and undesirable lengthening of the tendo achillis after free division. Such conditions were especially looked for in the 22 cases discussed and none were noted. It would seem, therefore, that the open operation is not at all necessary.

Children who have not taken a step, have been able to walk as a result of simple division or resection of the adductors and ham strings, and apparently much can be expected from the Tubby procedure of transferring the pronator radii teres to work as a supinator.

Considering the results of treating spastic paralysis by the injection of 80 per cent alcohol into certain nerves, it is shown in the cases reported that a return of the spastic contractures has not been prevented.

R. W. FRENCH

Hohmann, G.: Experiences with the Stöffel Operation for Spastic Paralysis. (Meine Erfahrungen mit der Stöffelschen Operation bei spastischen Lähmungen). *München. med. Wchnschr.*, 1913, lx, 1368. By Zentralbl. f. d. ges. Chir. u. i. Grenzgeb.

Hohmann's results with the Stöffel operation for spastic paralyses have been satisfactory. He operated twice on the tibial nerve in the popliteal space for spastic talipes equinus, once on the tibial nerve behind the internal malleolus for talipes cavus, twice on the median nerve above the elbow for flexed and pronated contracture of the hand, once on the median nerve above the wrist joint for flexed contracture of the thumb, and twice on the obturator nerve for adduction contracture of the hip joint. The operations on the median and tibial nerves were for cases of cerebral hemiplegia in children, and those on the obturator nerve for Little's disease.

On some of these tenotomies had been performed previously, and in others the tendons had been stretched or there had been tendon transplantation. In all of them improvement had occurred after these operations, but recurrences had set in. According to Hohmann, the cause of the failures of the previous treatments was that they could not decisively influence the central process which disturbed the muscular balance in the injured extremity. This can be accomplished only by decreasing the excitability in the muscles with the Stöffel operation. After the operation, complete healing of the wound must be awaited, and then a long-continued re-education therapy adopted. This after-treatment is a very essential factor in preventing recurrences. The Stöffel operation is especially adapted to cases of Little's disease and

spastic contractions following apoplexy in adults. It is not suitable for cases characterized by marked choreic movements, or for hydrocephalus and idiocy. On account of its safety it is much to be preferred to the Förster operation.

CREITE.

Ströbel, H., and Kirschner: Results of Nerve Suture (Ergebnisse der Nerven-naht). *Beitr. z. klin. Chir.*, 1913, lxxxiii, 475.

By Zentralbl. f. d. ges. Chir. u. i. Grenzgeb.

This report of fourteen cases of nerve-suture is especially valuable for the exactness of the details. It is not restricted to casual observations of the operative results, but makes note of the end-results on the basis of subsequent careful investigations.

Thirty-three per cent of the operations were entirely successful; three were complete failures. In one of the latter cases, however, a defect had to be bridged over. Other patients were materially benefited, although single muscle groups remained permanently paretic. The authors emphasize the fact that in cases of injury to the bones that is accompanied by paralysis, the nerve involved should be sought immediately as at that time the repair can be made more easily than later. Sometimes the injury to the nerve consists merely of a contusion by a fragment of bone, and by freeing the nerve a long-continued interruption of its function may be prevented. In the cases reported it was interesting to note that, contrary to our former observations, sensation, and especially the tactile sense, did not return till motor regeneration had taken place. Regeneration takes from six weeks to one year. Repair was always effected by means of simple suture. In one case the walls of a vein were wrapped about the point of suture.

The authors give a report also of two cases of injury to nerve plexus from stab wounds, in each of which the plexus was exposed. In one of these cases the scar tissue was removed from the nerve with partial success; in the other, there was a severe intraneural hæmorrhage, but the paralytic symptoms disappeared after six months without further development. At the end of six years the arm in one of these patients had fully regained its normal function.

SPITZY.

Katzenstein, M.: Nerve Plexus Grafts (Über Plexusfropfung). *Berl. klin. Wchnschr.*, 1913, l, 1165.

By Zentralbl. f. d. ges. Chir. u. i. Grenzgeb.

In a case of paralysis of the brachial plexus the suprascapular nerve of the healthy side was freed from its bed, from its origin to the incisura scapulæ, and brought behind the carotid artery and the jugular vein, between the œsophagus and the spine, to the diseased side. There it was sutured into an incision made in the plexus. The patient operated upon in this manner was a nine-year-old boy who, except for the ability to extend the fingers and flex the elbow slightly, suffered from complete paralysis of the upper arm. At the end of three months after the operation he was able to move the upper

arm in all directions, to flex the forearm and to extend and supinate it a little, to flex and pronate the hand, and to move the fingers in all directions. In a case of paralysis of the lumbo-sacral plexus the obturator nerve of the healthy side was liberated

in its entirety and carried behind the internal and external iliac arteries to the diseased side. This operation has been performed only once on the human being and such a short while ago that nothing can be said as yet in regard to the result. WREDE.

DISEASES AND SURGERY OF THE SKIN, FASCIA, APPENDAGES

Hendry: Report of an Interesting Bacteriological Finding in a Case of Pemphigus. *Surg., Gynec. & Obst.*, 1913, xvii, 85. By Surg., Gynec. & Obst.

Hendry reports the findings of a hitherto undescribed, anaërobic, slightly motile bacillus, isolated from the blebs of a case of pemphigus. The method of procedure was as follows: The surface of the bleb was seared and the fluid aspirated. The usual skin-contaminating organisms were found in aerobic culture; but cultures grown on human muscle anaërobically showed in from one to three weeks small white colonies. On microscopical examinations these colonies were made up of a very small, short, slightly motile bacillus in pure culture. No growth could be obtained by transfer to ordinary media, either aerobically or anaërobically, though transfers to new bits of human muscle were always successful.

A vaccine from the organism was prepared and given in increasing doses, the patient showing some improvement during the administration. The author does not feel that this is a proof of the curative value of the vaccinations, but suggests that it warrants more extensive investigation along these lines.

Loeb, L., and Sweek, W. O.: Histogenesis of Multiple Carcinoma of the Skin. *J. Med. Research*, 1913, xxviii, 235. By Surg., Gynec. & Obst.

Loeb and Sweek observed the changes that occurred in pieces of tumor that were removed from a patient affected with multiple carcinoma. The patient was a young man 33 years of age. The tumor, a growth of 12 years' standing, was located on the right side of the chin under the lower lip. About 3 years previous to the removal of the growth the patient was given Röntgen-ray treatment. At the time of its removal the tumor had involved the entire side of the face, part of the nose, the skin in the angle of the eye, and some superficial parts of the lower lip, so that in reality there were a number of definite and distinct lesions. The authors summarize their conclusions as follows:

The formation of multiple carcinoma of the skin depends on a primary increase in activity of certain parts of the epidermis. In this we have to deal with an affection of the epithelial cells which is independent of proliferative changes or of collections of round cells in the connective tissue, and of attractive influences of the blood vessels. In our case the proliferating energy of the epithelium which led to the formation of the multiple carcinoma was rela-

tively small. The infiltrating power of the proliferating epithelium was equally slight. In consequence of slight infiltrating power we may have an outgrowth of epithelium into the air instead of a downgrowth into the underlying cutis. In a certain relationship to deficiency in proliferating and infiltrating power stands perhaps the inability of the proliferating epithelium to undergo the normal metamorphosis of the surface epithelium into keratohyalin and keratin.

GEORGE E. BELLBY.

Joffe, M.: Free Fascial Transplantation; Experimental Investigations (Zur Frage der freien Fascientransplantation; Experimentelle Untersuchungen). *Chir. Arch. Veliaminova*, 1913, xxix, 466. By Zentralbl. f. d. ges. Chir. u. i. Grenzgeb.

The author carried out a series of experiments in free fascial transplantation, using the fascia of the tractus ileo-tibialis or that of the anterior sheath of the rectus. The transplantations were performed on the stomach, the colon, the urinary bladder, and the liver of cats. Thirteen of them were made on the stomach. Defects were first made in the wall of the stomach and then the mucosa alone was sutured. Next, the defects in the serosa and muscularis were closed with fascia. In one case the mucosa was not sutured before the fascia was transplanted. In this instance fascial necrosis and peritonitis resulted. In all of the other cases (the time of observation was 73 days) the results were good. At the end of 7 to 8 days there was complete union of the fascia with the stomach wall. The fascia was alive and new blood vessels had formed in it. The mucosa and submucosa had regenerated. The defect in the muscle remained. The fascia resembled a tendon. The nutrition of the fascia was derived from the walls of the stomach. In many cases adhesions had formed between the fascia and the omentum and a part of the new blood vessel formation was derived from the omental vessels. Adhesions to the omentum could be prevented only by resection of the omentum. The same results were obtained by the author in transplanting fascia into the bladder and colon. At the end of 62 days the urinary bladder had a perfectly normal appearance. When the mucous membrane defects had not been sutured, gangrene of the transplant and peritonitis always resulted. The experiments on the liver for the purpose of checking hemorrhage also gave good results.

On the basis of his work the author comes to the conclusion that fascia can be transplanted with

good results into the peritoneal cavity, especially for the purpose of reinforcing doubtful suture lines. As the fascia does not contract, stenoses do not result at the site of the transplantation. On the inner side of the fascial transplant new epithelium is formed in about 50 days, and the secretory function of the stomach therefore does not suffer.

To these experiments the author adds a description of a case of fæcal fistula following appendicitis, from the Manteuffel clinic. In this instance when the mucous membrane was sutured a piece of fascia from the anterior rectus sheath was sutured over it to reinforce it. With the exception of partial fascial necrosis complete recovery resulted. HESSE.

Kornew, P.: The Free Transplantation of Fascia (Über die freie Fascientransplantation) *Beitr. z. klin. Chir.*, 1913, lxxxv, 144.
By Zentralbl. f. d. ges. Chir. u. i. Grenzgeb.

Kornew gives an exhaustive review of the abundant experimental and clinical material concerning

free fascia transplantation. His own material is divided into a clinical and an experimental part. His numerous experiments confirm and supplement previous work. A new feature is the successful closing of defects in the chest wall by transplantation of fascia. Eighteen cases are reported. The procedure was used in twelve cases to strengthen the muscle sutures in operations for inguinal hernia, and once each to close the internal ring in crural hernia, to close a defect in hernia pulmonalis, to repair a defect in the pleura in a penetrating wound of the chest, for a plastic operation on the sphincter in place of Thiersch's metal ring in a case of prolapse of the anus, to fix the testicle in a case of retention of the testicle, and to mobilize an ankylosed mandibular joint. In all except one case there was union of the transplanted fascia and the clinical results were satisfactory. The author does not give a sufficient number of references to the literature nor substantiate his statements by clinical evidence either for or against his procedure. REHN.

MISCELLANEOUS

CLINICAL ENTITIES — TUMORS, ULCERS, ABSCESES, ETC.

Tyzzer, E. E.: Factors in the Production and Growth of Tumor Metastases. *J. Med. Research*, 1913, xxviii, 309.
By Surg., Gynec. & Obst.

In this study and series of experiments the author attempts to answer the following questions:

In patients in whom metastasis has already occurred will the growth of the secondary masses be accelerated by the removal of the primary tumors, and will such removal shorten life or prolong it?

Do the procedures followed in the course of physical examinations and surgical operations increase or diminish the incidence of metastases?

In his experiments Tyzzer made use of mice, and the results he obtained seem to furnish rather conclusive proof that mechanical force is an important factor in the causation of metastasis. Moreover, the author is convinced that metastasis is dependent also upon a number of other determinable factors, of which the biological character of the tumor tissue is of first importance. In certain propagated tumors second deposits are rarely or never observed, while in others they are frequent. This is true also of the various types of spontaneous tumors. Tyzzer believes that the mechanism by which tumor cells are set free in the circulation depends to a great extent upon the structural character of the tumor and the peculiarities of its growth; undoubtedly also to its age and size. This his experiments clearly show. Metastases of the tumor of the waltzing mouse may be produced experimentally by the application of intermittent pressure such as massage or gentle pinching. The results obtained

in this investigation, according to the author, find practical application in the management of tumor patients. From them every physician should realize the irreparable harm that may result from the manipulation of malignant tumors in their early development. GEORGE E. BEILBY.

Stewart, J. C.: The Malignancy of Giant-Celled Sarcoma. *Surg., Gynec. & Obst.*, 1913, xvii, 30.
By Surg., Gynec. & Obst.

The object of this article is to disprove by the citation of cases the statements made freely in current literature that giant-celled sarcoma is benign and never forms metastases. Two cases are cited, both of which caused death, and one of which formed several metastases. The first was that of a central giant-celled sarcoma of the metatarsus; death resulted from multiple metastases. The second was that of a central giant-celled sarcoma of the humerus which caused a pathological fracture of the bone, and death by local recurrence.

Falta, W.: Diseases of the Glands of Internal Secretion (Die Erkrankungen der Blutdrüsen). Berlin: Springer, 1913.
By Zentralbl. f. d. ges. Chir. u. i. Grenzgeb.

Falta's clinical work is an excellent supplement to Biedl's classical work on the experimental physiology and pathology of the internal secretory glands. These he defines as glands that excrete directly into the circulation a hormone with powerful physiological effects. Adrenalin is the only one that is defined chemically. Each ductless gland has its specific function. They cannot compensate for one another, although disease caused by abnormality of

function in one may be modified by a pathological condition in another. The great variety in symptomatology may be explained as being due to disturbances in these glands and to differences in the constitutions of the patients.

The diseases of the thyroid gland are divided into two classes, those characterized chiefly by local symptoms, such as goiter, tumors, and inflammations, and those characterized by an increase or decrease in the secretory function. Basedow's disease is caused by hyperactivity of the thyroid with secondary involvement of other glands. Falta does not believe in the combination of Basedow's disease and myxœdema recognized by many experienced surgeons; he concludes that the myxœdematous symptoms are the result of insufficient functioning of the hypophysis. He does not attach much importance to the involvement of the thymus. Operation should not be advised for mild cases in patients in good circumstances, or those with neuropathic tendencies. Long delay is unwise. The advice frequently given to refrain from operation when the X-ray shows a thymus shadow is not approved. Falta has observed good results from X-ray treatment. On account of the sclerotic changes in aplasia of the thyroid, old age has been compared with chronic myxœdema, but reckless thyroid medication in old age must be avoided. Sporadic cretinism is a hypothyroid or a thyroid condition of a poorly-developed organism. The more severe forms are characterized by lack of development of the bones and blood-forming organs, the ductless glands, and the central nervous system.

Mild cases of thyroid weakness recover spontaneously or under treatment with thyroid tablets. In severe cases the ideal treatment by transplanting a new thyroid is not possible, for only auto-transplantation has permanent results. While thyroid medication is effective in the myxœdema of adults, in sporadic cretinism it is of value only in the milder forms and when begun very early. In such cases the effect on growth is very marked. Endemic cretinism and goiter are related. Goiter is caused by drinking-water, and is due probably to a toxin or toxalbumin of organic origin. Iodine treatment is effective in proportion to the degree to which the changes are hyperplastic rather than degenerative. Falta believes that endemic and sporadic cretinism are not identical and that thyroid disturbance is not the only cause of the endemic form. The toxin of cretinism injures the central nervous system and other tissues as well as the ductless glands directly. The thyroid factor may be of greater or less importance. Therefore, thyroid medication varies in effectiveness in different cases.

Tetany has been shown to be the result of insufficiency of the epithelial bodies, which are found in the thymus as well as the thyroid. These bodies produce a hormone which influences the calcium metabolism in the central nervous system. When they are deranged in function there is loss of

calcium in the ganglion cells of the spinal cord and consequently a condition of hyperexcitability. Different forms of tetany are discussed. The epithelial bodies continue to function in auto-transplantation of the thyroid. Opinions differ as to the value of calcium medication. Falta has seen no effect from it. There are some errors in the section on diseases of the thymus. Hyperfunction of the hypophysis causes acromegaly. There is an interesting discussion of the causes of a combination of acromegaly with symptoms of Basedow's disease or myxœdema. Decreased activity of the hypophysis causes hypophyseal dystrophy. Administration of an extract of hypophysis is effective. Cysts and gummata may occur in the epiphysis. Tumors are found chiefly in young males, so that it is probably a question of congenital abnormality of development. Pressure symptoms and trophic disturbances are marked — precocious development of the body and premature development of the genitals. We think it possible that the trophic effects of pineal gland tumors affect the suprarenal glands, causing hyperplasia. Operation has never been attempted.

In Addison's disease there is lymphocytosis, and frequently status lymphaticus, hyperplasia of the thymus, and atrophy of the genital glands. Decreased function of the suprarenal glands is caused generally by tuberculosis or tumors, but may result from hæmorrhage or thrombosis. Sclerosis may be caused by syphilis. The special affinity of diphtheria toxin for the suprarenal glands is noteworthy as a cause of heart failure. Adrenalin is a hormone affecting this sympathetic system. It is used with good results subcutaneously in collapse, and by the mouth for abstracting œsophageal cancer and for phosphorus poisoning. Hyperfunction of the suprarenals may be caused by tumors of the chromaffin tissue. Adenoma of the cortex may cause increased development of the body and premature development of the genitalia with various abnormalities in the sexual sphere. Early castration causes incomplete development of the genitalia and increase in stature. Late castration causes contraction of the prostate. Eunuchoids, without being castrated, resemble eunuchs. This condition sometimes occurs in adult life as a result of diseases of the genital glands (trauma, syphilis, gonorrhœa, gummata, sexual abuse, alcoholism). In sexual defects in men, thyroid, radium and pituitrin treatment is recommended, and in women, organotherapy and transplantation of the ovaries.

Falta's multiple ductless-gland sclerosis is an infectious disease that involves the greater part of the ductless gland system. It can be diagnosed clinically from symptoms of hyperthyroidism, eunuchoidism, insufficiency of the hypophysis, symptoms of Addison's disease, and cachexia. There is no definite picture from the point of view of pathological anatomy. Falta explains gigantism as an abnormal predisposition of the entire ductless gland system. Infantilism is due to a developmental disturbance of the entire organism of which the

faulty development of the ductless glands is only a part.

Mongoloids are the result of exhaustion; that is, they are the last-born of families with numerous children. In the chapter on the pancreas Falta says that pancreatic lithiasis is frequently combined with cholelithiasis and that it is part of a family tendency to stone-formation, which leads to indurative pancreatitis with glycosuria in 34 to 35 per cent of the cases. The question of the relation between the trauma and diabetes is important surgically. Sugar is found in 23 per cent of head injuries.

The concluding chapter treats of the different forms of obesity. Adipose dolorosa is not thyroid in origin, though thyroid treatment often shows good results. Falta has contributed much to the understanding of this very difficult subject by his clinical material. The illustrations are very helpful. The bibliography aids special study. KLOSE.

SERA, VACCINES, AND FERMENTS

Lesser, K., and Kögel, H.: Experimental and Clinical Results Obtained with Rosenbach's Tuberculin (Über Tuberkulin Rosenbach; Experimentelle und klinische Erfahrungen). *Beitr. z. Klin. d. Tuberkul.*, 1913, xxvii, 103.

By Zentralbl. f. d. ges. Chir. u. i. Grenzgeb.

The authors attempt to answer the three following questions: 1. Are there differences in the form of tuberculosis in treated and untreated animals? 2. Is there a difference in animals treated with old tuberculin and with Rosenbach's tuberculin? 3. Do the preparations have a specific effect on the animal body? Nine guinea pigs were injected with 1 mg. each of a strain of tubercle bacilli of the human type grown directly from the sputum. Nine others were injected with 0.5 mg. each of a culture of bacilli. All of the infections were severe. Some of the animals were treated with Rosenbach's tuberculin, some with old tuberculin, and some not treated at all. A few of the animals were killed soon afterward, and the blood was withdrawn for the purpose of demonstrating by complement fixation tests whether it contained antibodies.

In the first series, the animals treated with old tuberculin seemed to show greater length of life than those treated with Rosenbach's tuberculin. In the second series there was no marked difference. As to the form of the tuberculosis, the treated and untreated animals showed no difference. The former did not live any longer than the latter. In the animals which lived longest, whether they were treated with Rosenbach's tuberculin or with old tuberculin, glandular and pulmonary tuberculosis was most marked, while in those that died early, general miliary tuberculosis was the prevailing form. In answer to the third question, it was found that there was no fever, disturbance of the general health, or infiltration around the site of the injection. A fall of temperature after an injection of 5.5 ccm. of the Rosenbach tuberculin, resembling an anaphy-

lactic attack, was noted as a specific effect of tuberculin. The complement fixation tests showed the presence of specific antibodies against the Rosenbach tuberculin. Genuine recoveries were not observed with either form of tuberculin. Rosenbach tuberculin is to be regarded as a mild form of tuberculin.

With regard to the clinical effects noted, Rosenbach tuberculin showed only a cutaneous reaction and this only exceptionally and when given in concentrated solution. For the intracutaneous reaction it was shown to be 1000 times less effective than the old tuberculin. In the diagnostic subcutaneous test the Rosenbach tuberculin always showed a marked reaction around the site of injection. The general symptoms were more violent and more unpleasant than those caused by the old tuberculin. Marked infiltration, pain, and lymphangitis were frequent. The reaction at the site of injection which appeared even with the smallest doses that had no other effect, were to be explained not only as being purely a specific effect of tuberculin, but as due partly to the albumose content (trichophyton products). Perceptible focal reactions appeared only after injections of 1 mg. of Rosenbach's tuberculin; therefore 5 mg. is not sufficient for a diagnostic injection.

In diagnosis the Rosenbach tuberculin has no advantages. It was used therapeutically on twenty-one patients according to Rosenbach's directions, but probably with more cautious dosage. High temperatures could not be avoided in many cases. The cases used for treatment were severe but not hopeless. The severity of the local reaction several times necessitated giving up the treatment. The influence on the general condition and the subjective symptoms was as a rule good. In twelve cases the clinical findings and the general condition were markedly improved. All of these cases were tolerant of the Rosenbach tuberculin, while those that turned out badly reacted much more strongly. The authors attribute the failures, severe reactions, etc., partly to the fact that the cases selected for the treatment were unsuitable. Acute and subacute cases with extensive distribution should be excluded. Reactions should be avoided. In the dosage it is to be noted that focal reactions appear sooner than general reactions, and, especially in severe cases, a cumulative effect must be counted on. Large initial doses should be avoided. Toxic substances are small in amount as compared with antigens but they are present. The presence of foreign, non-specific albumoses is a disadvantage, for they are in part responsible for a marked local reaction. HARRASS.

Lewin, C.: The Treatment of Cancer Patients by Vaccination (Die Behandlung von Krebskranken mit Vaccination). *Therap. d. Gegenw.*, 1913, liv, 253.

By Zentralbl. f. d. ges. Chir. u. i. Grenzgeb.

The author's experiments on animals convinced him that autolysins of tumors have a beneficial

therapeutic action. The results justified the application of the principle to the treatment of human beings. An autogenous vaccine was made from the extirpated tumors to test their therapeutic value in lessening recurrences and destroying metastases. The author cites two cases that were affected favorably by the vaccine, and very emphatically recommends its use in suitable cases of cancer. SZÉCSI.

Ruediger, E. H.: The Duration of Passive Immunity Against Tetanus Toxin. *Philippine J. Sc.*, 1913, viii, 139. By Surg., Gynec. & Obst.

The attempt is made to determine the duration of passive immunity against tetanus toxin by a series of experiments upon both horses and guinea pigs. The experiments are grouped under the following three heads:

1. The duration of passive immunity in the horse, after the injection of homologous antitetanic serum.
2. The duration of passive immunity in the guinea pig after an injection of antitetanic serum from the horse, preceded by repeated injections of antitetanic serum from the horse.
3. The duration of passive immunity in the guinea pig after an injection of antitetanic serum from the horse, preceded by repeated injections of normal horse serum.

The author reaches the following conclusions:

1. The subcutaneous injection of 1,500 units of antitetanic serum from the horse into the horse confers passive immunity of between six and eight weeks' duration.
2. Guinea pigs subjected to repeated inoculations with antitetanic serum from the horse do not acquire the power to eliminate it more rapidly; they acquire a tolerance as is shown by a longer immunity.
3. Guinea pigs treated with repeated injections of normal horse serum acquire a passive immunity following the injection of antitetanic serum from the horse, that is of longer duration than the immunity of untreated guinea pigs. J. H. SKILES.

BLOOD

Ordway, T., and Kellert, E.: The Complement Content of the Blood in Malignant Disease. *J. Med. Research*, 1913, xxviii, 287.

By Surg., Gynec. & Obst.

The authors have noted that in many cases of cancer and leukæmia the blood shows such striking numerical and morphological changes as to make it seem possible that alterations in the function of the cells or plasma might be detected by examining certain biological properties of the serum. Their article deals with the hæmolytic power of the serum, with particular reference to its complement content. By their studies it seems proven that in the majority of cases the hæmolytic complement content of the blood serum in the different varieties and stages of human cancer is relatively constant. The amount is practically the same as that found in health and in persons suffering with certain other diseases.

Such human serum in most cases contains one-tenth to one-twentieth as much hæmolytic complement as pooled serum from adult guinea pigs.

There is no increase of hæmolytic complement in myelogenous or lymphatic leukæmia. The hæmolytic complement content of the plasma of citrated human blood does not differ from that of the serum.

GEORGE E. BEILBY.

Friedman, M.: Prolonged Intravenous Infusions (Über intravenöse Dauerinfusion). *München. med. Wchnschr.*, 1913, lx, 1022.

By Zentralbl. f. d. ges. Chir. u. i. Grenzgeb.

Proctoclysis is destined to supercede subcutaneous and intramuscular infusions. However, in cases in which the patient is unable to retain the fluid the retention of which causes — as in peritonitis — unpleasant sensations of fullness in the abdomen, the intravenous infusion of Haidenhain is the best method for administering fluids as well as medications. It has been shown that a rapid intravenous infusion, especially with the addition of larger doses of adrenalin, produces a marked increase in the vascular tonus and is dangerous for the heart. The author, therefore, has adopted the method of prolonged intravenous infusion, according to which only small quantities are infused at a time and the period of infusion is extended over many hours. The technique is the usual one, except that the cannula, the arm, and the funnel filled with the fluid must be securely fastened. To regulate the flow, a pinch-cock is attached to the rubber tube.

Friedman has obtained the following impressions from his method: (1) That in the administration of salt, adrenalin, and digalen solutions by the drop-method the blood pressure rises, not suddenly, but gradually, and remains at the same level during the period of infusion. (2) That this method has no by-effects. (3) That it causes no excessive burden for the heart. (4) That with slower infusions the heart can sustain larger quantities of fluid, so that a better flushing out of the organism and diuresis are obtained. NEUMANN.

BLOOD AND LYMPH VESSELS

Geinitz, H. T.: The Treatment of Varices with a Spiral Incision (Zur Behandlung der Varicen mittelst des Spiralschnittes). *München. med. Wchnschr.*, 1913, lx, 1257.

By Zentralbl. f. d. ges. Chir. u. i. Grenzgeb.

The author reports the later results obtained by Rindfleisch's operation for varices performed at Garré's clinic. In six cases the immediate result did not seem satisfactory, but the later examination of five cases, one and one-half to two years after the operation, showed a surprisingly good result. The ulcer cruris recurred only once and then it did not cause trouble. For diffuse varices and in cases where simple ligating methods have failed, the spiral incision is recommended, though a sure and ideal result cannot be guaranteed. WOLFF.

POISONS

Fejes, L.: Coli Sepsis (Über Kolisepsis). *Beitr. z. Klin. d. Infektionskrankh. u. z. Immunitätsforsch.*, 1913, i, 575. By Zentralbl. f. d. ges. Chir. u. i. Grenzgeb.

Beside its morphological and biological characteristics, the ability of the bacillus coli to alter its virulence and to take on a decided pathogenic character is the cause of the general infection known as colibacillosis. The infection may be ectogenous and, like typhus, be caused by contaminated drinking water. Also ectogenous are the poisonings of meat caused by the bacillus coli. In these cases the bacilli involved vary so greatly from the normal type of colon bacillus that they have been regarded as a special type, described as the paracolonic bacillus and supposed to stand between the typhus-paratyphus bacillus and the typical colon bacillus.

More frequent than the ectogenous infection is the endogenous infection of the organism with its own bacilli. It is not yet definitely known just what causes the change in the virulence of the bacilli in this case, but it is believed that changes in the intestinal wall are chiefly responsible. The symptoms of the infection are varied, due to the fact that the infection may start in various parts of the body. However, chills and very high temperature followed daily by decided drops make the temperature curve of the condition very characteristic. Localized foci, endocarditides, broncho-pneumonic processes, suppurations in the different organs, etc., all have their own particular symptoms. The diagnosis may be confirmed by cultures made from blood taken shortly after the chills or from pus from a local suppuration. In the general infections originating from the intestinal tract the bacilli enter the blood by way of the local foci in the intestinal wall through anatomical lesions or disturbances of the intestinal circulation.

To these infections belong, beside coliangina, diseases of the vermiform appendix, peritonitis, dysenteric processes caused by amœbæ or bacilli, typhus abdominalis, and cholera. More distantly related are the ascending infections of the bile duct caused by biliary engorgement, the results of which are lithogenous catarrh and calculous cholangitis, which are the forms of local affections of the biliary apparatus that are the entrance foci for the general septic infection. The urinary tract, which often under nearly normal conditions contains bacillus coli, is infected from without by hæmatogenous infection of the kidneys or from the lymph ducts of the neighboring organs, and particularly those of the rectum. Also in this case stasis and trauma may be the cause of the change in the virulence of the bacilli and of the resulting general septic symptoms which originate as a rule from bacillus coli infection of the pelvis of the kidney. A description is given in the article of colibacillosis in puerperium and after septic abortion. An extensive bibliography is appended.

W. GOEBEL.

SURGICAL THERAPEUTICS

Burnham: Hexamethylenamine in Surgery. *Med. Rec.*, 1913, lxxxiv, 15. By Surg., Gynec. & Obst.

The main use of hexamethylenamine in therapeutics until very recently has been in the treatment of disorders of the urinary tract. It has been shown that the drug appears in the urine within an hour or so after administration, and, along with it, an appreciable amount of formaldehyde is found. The antiseptic properties are in all probability due to the formaldehyde. Lately the drug has been found in the cerebro-spinal fluid, blood, bile, saliva, middle ear, anterior chamber of the eye, and in many other regions of the body.

The use of hexamethylenamine, according to the author, is indicated in most surgical conditions accompanied by inflammation. In cystitis, pyelitis, meningitis, acute cholecystitis, middle ear infection, and in many other conditions its use has been accompanied by marked improvement. It should be given also as a prophylactic measure before catheterization or cystoscopic examination. In compound fractures of the skull it seems to prevent a succeeding meningitis in some cases.

It should be given in fairly good-sized doses, usually from 40 to 60 grains daily. In some conditions, such as meningitis and cholangitis, even as high as 300 grains may be given in the 24 hours. Irritation of kidneys and stomach may be largely avoided by giving plenty of water and alkali. J. H. SKILES.

ELECTROLOGY

Jackson: Conservative Surgery from a Röntgenologic Standpoint. *Am. Quart. Röntgenol.*, 1913, iv, 209. By Surg., Gynec. & Obst.

Most cases of malignant tumor should not be considered operable since they cannot be cured by operation. If a neoplasm will recur in a few months after operation, the case should be refused by the surgeon and palliative measures only used. Most malignant growths of the larynx are incurable by operation. Out of seven hundred cases seen by the author, one out of fifty-two was operated. The other fifty-one were refused operation because of their type or position, or both. The growth after recurrence is much more destructive of life than if it had not been treated surgically. A few laryngeal neoplasms situated at the anterior commissure can be extirpated completely without recurrence. The majority involve the posterior lymphatics communicating with those in the neck or the tissues adjacent to the œsophagus.

A plea is made for the further development of the technique in radiotherapy, which gives in most cases a beneficial palliative result and, in some, a permanent cure. This method should be more widely used instead of surgical operations, which after a short period hasten rather than palliate the disease. The author has already seen in radiotherapy sufficient benefit to encourage therapists to give more attention to growths of the larynx. HOLLIS E. POTTER.

GYNECOLOGY

UTERUS

Obata, J.: A Statistical Contribution to the Morphology of Uterine Carcinoma (Statistischer Beitrag zur Morphologie des Uteruscarcinoms). *Arch. f. Gynäk.*, 1913, xcix, 474.
By Zentralbl. f. d. ges. Gynäk. u. Geburtsh. s. d. Grenzgeb.

The author examined the Meyer collection of microscopic preparations of carcinoma of the uterus in order to compare them with the preparations of Schottländer and Kermauner and their classification according to morphological characteristics. He makes the following groups: 1. Primary solid tumors. 2. Primary glandular, in part secondary, solid tumors.

Among two hundred and forty-four cases of uterine carcinomata there were one hundred and thirty-four primary solid tumors and one hundred and twelve primary glandular forms. Among the primary glandular tumors there were forty-seven pure glandular and sixty-five primary glandular forms, which, however, had to be considered secondary solid tumors. Among the one hundred and twelve primary glandular carcinomata there were eighty-eight corpus and sixteen cervix carcinomata and one portio carcinoma; in seven cases a decision was impossible. Among two hundred and forty-four uterine carcinomata there were twelve pure glandular forms without a mixture of the epithelium. Nine of these were situated in the corpus and three in the cervix and they were considered by the author to be malignant adenomata.

A description is given of the glandular form, with and without multiple layers of the epithelium, and also of the primary glandular forms, including the secondary solid carcinomata. In the series of one hundred and thirty-four primary solid tumors there were one hundred and twenty cervical, and eleven corporal, carcinomata. In three no classification was possible. The author divides these into large, small, and mixed alveolar types, and, upon the basis of the quantity of interstitial tissue, into medullary, scirrhous, and mixed types. Among one hundred and thirty-four primary solid carcinomata there were fifty-four large alveolar, twenty-four small alveolar, forty-three mixed alveolar, and twelve diffuse forms; sixty-two scirrhous, sixty-five medullary, and three mixed types in which the diffuse form was classified as belonging to the medullary type.

The author tabulates these carcinomata as do Schottländer and Kermauner, according to the relation between the interstitial tissue and the cancer-cell nests and also according to the degree to which the cancer cells have migrated into the lymph stream and tissue clefts. Among one hundred and seventy-

one cases there were fifty-two corporeal and one hundred and fourteen cervical carcinomata; in five no decision was rendered. More detailed information in regard to the structure of uterine cancer, with respect to giant cells, glycogen, mucin, infiltration, vessel formation, extension by way of the bloodstream and lymphatics, central degeneration of cancer-cell nests, and atrophy of the cancer cells will be found in the original work. MORALLER.

Pinkuss: Treatment of Cancer with Mesothorium Emanations (Krebsbehandlung mit Mesothorbestrahlung). *Deutsche Gesellsch. f. Gynäk.*, Halle, 1913, May.

By Zentralbl. f. d. ges. Gynäk. u. Geburtsh. s. d. Grenzgeb.

Pinkuss has, so far, successfully treated twenty-two cases of cancer with mesothorium emanations. His results improve with the improvement in his technique. He also observed deep-reaching actions of the γ -rays. Continued raying of the cancer area enables one to reach deeper and deeper portions in the course of time. However, this favorable result may be undone by the formation of metastases in the meantime. The success of mesothorium raying depends on the way in which the cancer extends and especially on the degree of malignancy. The permanent results are more favorable in slowly growing cancers which occur especially in older people.

The danger of injuring neighboring organs such as the urinary bladder, adherent intestinal loops, and the ureters, should not be overlooked. Pinkuss noted severe hæmorrhage from the uterine vessels during the raying of a cancer crater reaching laterally into the parametrium. The use of mesothorium is indicated in cases of cancer which are not operable on account of the age of the patient or other severe organic diseases, in all inoperable cancers and recurrences and as a prophylactic to recurrence following operations.

Considering the recent views of cancer, he uses, besides the raying, other medicinal measures, as the intravenous injections of Thor-x and atoxyl and internal doses of Thor-x and pancreatin. He never observed an objective success with the use of Thor-x given either per os or intravenously without using other additional measures of treatment. A dangerous side-action of intravenous injections of Thor-x is not to be feared if the dosage is watched. The combined method of treatment makes it possible to use medium doses of mesothorium. The author had encouraging results with the use of mesothorium in myomata and metropathia hæmorrhagica. These treatments were begun during July, 1912. In seven cases of metropathia, amenorrhœa was induced

in three, and oligomenorrhœa in three. In four cases of myomata he obtained amenorrhœa twice. The cases have been under observation for several months. The duration of the treatment was between six and twelve weeks.

Vautrin: A Consideration of Cystic Tumors of the Uterus of Congenital Origin (Considération sur les tumeurs kystiques de l'utérus d'origine congénitale). *Ann. de gynéc. et d'obst.*, 1913, x, 352. By Journal de Chirurgie.

In connection with a description of two cases of submucous tumors of the uterus, one of which caused an inversion of the uterus in a young girl and was examined histologically, Vautrin protests against the general tendency to believe that all cystic tumors originate in the Wolffian ducts.

Without doubt the Wolffian ducts, which are closely connected with the Müllerian ducts, are the cause of a certain number of these cyst formations, but malformations of the ducts of Müller also play an important part.

Since malformations of the vagina have been ascribed to deviations in the ducts of Müller, and since any anomalies in shape, position, and development of the tube are likewise related either to lack of development or to over-development of these ducts, why not also admit that an exaggerated growth is possible even in the uterus itself? In the development of the genital organs various evolutions in the epithelium are noted. Thus, the epithelium differs in the corpus, the cervix, and the portio. Numerous budding phenomena are observed in the formation of the uterus and its numerous glands. An aberration during these profound changes would not be impossible.

According to Meyer, the encysting that affects the organs of Müller might take place at the three following periods: 1. When the two canals of Müller occupy a median line and are supported on the sides by the canals of Wolff. 2. During the joining of the canals of Müller. 3. During the separation of the canals of Müller and the Wolffian ducts.

Vautrin states that when the epithelium covering the cyst is polymorphous in appearance, cylindrical in certain areas and flat-celled in others, the cyst undoubtedly may have originated in the ducts of Müller. Cysts that have originated in the Wolffian ducts are covered entirely with cylindrical epithelium.

In certain exceptional cases this origin may be recognized by a close study of the decidua in normal or ectopic pregnancy. In a case of ectopic pregnancy reported by Ferroni numerous decidual elements were found at the center of an adenomyoma, collected beneath a cavity formed by cylindrical epithelium which had its origin in the Müllerian ducts.

Vautrin asks further if very often at the center of adenofibroma there do not exist rests of Müllerian epithelium from which, by encystment, conjunctive reaction of fibroma may occur. L. CHEVRIER.

Kalledey: The Etiology and Organo-Therapy of Uterine Hæmorrhages (Zur Lehre von der Ätiologie und Organotherapie der Uterusblutungen). *Deutsche Gesellsch. f. Gynäk.*, Halle, 1913, May. By Zentralbl. f. d. ges. Gynäk. u. Geburtsh. s. d. Grenzgeb.

Kalledey treated twenty-one cases of dysmenorrhœa by the administration of ovarian extract, and observed the immediate cure not only of the local, but also of the nervous, symptoms. Five of the twenty-one patients became pregnant during the treatment. This fact leads the author to conclude that, with the regulation of the internal secretion, the condition that favors conception also is influenced favorably.

On the basis of his results the author believes that the cause of dysmenorrhœa is hypofunction of the ovary. Forty-one cases of menorrhagia and metrorrhagia he treated successfully with hypophyseal extract. In five cases of hæmorrhage he effected a cure by the use of corpus luteum extract. One of these patients had been previously treated unsuccessfully by all other known means.

In Kalledey's opinion his results confirm the theory that uterine hæmorrhages are due to correlative disturbances in the organs of internal secretion. He leaves open the question as to whether the results were produced directly by the hormones used or by the hormones produced through the stimulation afforded by the injected material.

Kaiser: An Obstinate Metrorrhagia (Een hardnekkig geval van Metrorrhagie). *Nederl. tijdschr. v. geneesk.*, 1913, No. 18, 1227. By Zentralbl. f. d. ges. Gynäk. u. Geburtsh. s. d. Grenzgeb.

The author used 20 cc. of horse serum subcutaneously and tamponed the uterus with a solution of gelatine with immediate and perfect success in a case of uncontrollable menstrual metrorrhagia. The subcutaneous injection of 20 cc. horse serum in another case of uncontrollable hæmorrhage from the uterus also was followed by an immediate and perfect cure. Symptoms of anaphylaxis were slight.

STRATZ.

Lawrence: Double Uterus and Vagina. *Southern M. J.*, 1913, vi, 477. By Surg., Gynec. & Obst.

The author reports the case of a married woman, forty-eight years old, who had never been pregnant. He was consulted owing to irregular bleeding. An examination showed a vaginal septum and two cervixes.

In opening the abdomen the first appearance of the uterine fundus was that of a bicornate uterus. The left tube was not attached to the broad ligament, but lay free in the abdominal cavity. The left ovary occupied a pocket in the broad ligament adherent to the uterine body. The right tube and ovary were normal. Two vaginal canals were demonstrated.

This was a case of uterus bilocularis. Several small myomata were found in the uterine wall.

C. H. DAVIS.

Murphy, J. B.: Procidentia Uteri: Murphy's Method of Fixing the Uterus. *Surgical Clinics of John B. Murphy*, 1912, ii, No. 3.

By Surg., Gynec. & Obst.

The patient was 56 years of age and the trouble was of 33 years' standing. With the woman in the Trendelenburg position, a transverse semilunar incision 6 in. long was made 1 in. above the symphysis. The tissues were divided down to the aponeuroses of the recti. The latter were then freed from fat over an area 1 in. wide and as long as the incision, and their edges retracted. The right rectus was then incised for 2 in., close to the median line and parallel to its long axis. This incision was extended through the peritoneum. The fundus, grasped by a vulsella, was brought out through the opening until the cervicocorporeal portion was clearly in view. The round and broad ligaments were then clamped with hæmostats on either side down to the cervicocorporeal junction and cut free from the uterus down to the tip of the forceps. The stumps were ligated, and the tips sewed accurately to the cervicocorporeal junction. This portion was then slipped back into the abdomen. Thus the body of the uterus was left bare and free above the level of the divided recti.

The peritoneum was next sutured accurately around and to the circumference of the cervicocorporeal portion of the uterus. In this way the peritoneal cavity was closed. The uterus was then split through the middle from before back, parallel to the long axis of the body, down to the cervicocorporeal junction. It was opened laterally to form two wings. The mucosa was next cut off, clear out through the divided cornua down to the cervix, and removed. The two lateral flanges of uterine muscularis were then sewed firmly to the aponeurosis of the rectus all the way around, making a bat-like flange over the recti. Finally, the divided edge of the aponeurosis of the rectus was tightly closed about the cervicocorporeal portion. The skin and fatty tissues were united and a small drain left in at the lower angle of the wound.

When this method is used the uterus can never get back into the abdomen. The traction on the anterior vaginal wall holds the bladder in position; that on the posterior vaginal wall holds the rectum. The only intra-abdominal work is the detaching of the broad ligaments. The stumps of these are covered by suturing; therefore no abraded surface is left within the peritoneum at the completion of the operation. If the operation is performed before the menopause, great care should be taken to remove all of the uterine mucosa; otherwise periodic hæmatoma will form at the menstrual periods. The operation can be performed in 20 minutes. L. J. MITCHELL.

Kuhn: A New Procedure for the Relief of the Retroverted Uterus. *J. Okla. St. M. Ass.*, 1913, vi, 79.

By Surg., Gynec. & Obst.

In this article the author gives his ideas as to the cause of symptoms and his operative treatment for the simple retroverted uterus. He states that many

women have a retroversion and have no symptoms at all, but that those suffering from this condition suffer through a ptosis of the abdominal and pelvic viscera, causing an engorgement and finally a varicosity of the pampiniform plexuses and incarceration of one or both ovaries within the folds of the rolled broad ligaments. A previous inflammatory pelvic condition or a relaxed perineum will also cause varicosities of the broad ligaments.

Treatment. The pampiniform plexuses are both ligated. The outer ends at the pelvic border are first tied in front, leaving the ligatures long; then the uterine ends are tied in the same way, the static blood being then expressed through an incision. This leaves the infundibulo-pelvic ligaments relaxed, so they are plicated through an opening made in the anterior border of the broad ligament. The peritoneum is then closed over this plication by a pursing suture. A ventro-suspension is now done with a long loop of cat-gut in order to temporarily relieve tension on the tender ligaments. The round ligaments are not disturbed.

EUGENE CARY.

Davis, C. G.: A Review of the Literature and Case Reports of Ruptured Uterus. *Surg., Gynec. & Obst.*, 1913, xvii, 51.

By Surg., Gynec. & Obst.

Most ruptures of the uterus are probably incomplete at first, and are not recognized until after the rupture of the peritoneum. In order to make a fair comparison of complete and incomplete rupture, and especially of the methods of treating them, the statistics of both should be considered together. Following these statements Davis discusses rupture of the uterus in regard to its etiology and frequency. As to the extent to which rupture involves the uterus, the author found in his study of the cases collected by Trask, that during pregnancy 68 per cent involved the body or fundus and 32 per cent the cervix; during labor, 8.5 per cent involved the fundus, 36 per cent the body of the uterus, and 55.5 per cent the cervix; in a total of 374 cases in which the site was mentioned, 53 per cent involved the cervix, and 46.2 per cent the body and fundus.

The probability that rupture will follow the modern Cæsarean section is not great, and in most cases should not be used as an argument in favor of sterilizing or performing the Porro operation. Section cases should be carefully watched during the latter months of subsequent pregnancies, and when there is pelvic deformity, overdilatation of the uterus, or some question as to the integrity of the old scar area, Cæsarean section should be performed several days before the expected onset of labor. Under no condition should the patient undergo the strain of the second stage of labor.

Treatment by tamponade and binder is a good temporary measure and may give good results in the incomplete cases where there is little hæmorrhage, but in all classes of cases statistics indicate that operative treatment gives better results than conservative treatment.

Werboff, J.: The Uterus of Woman; Its Normal Function and Its Rupture Incident to Labor (Die Gebärmutter des Weibes, ihre normale Arbeit und ihre Zerreibungen während der Geburt). Berlin: Karger, 1913.

By Zentralbl. f. d. ges. Gynäk. u. Geburtsh. s. d. Grenzgeb.

The author lays down the general principles of the law governing the physiology of hollow organs of the body, namely the law of "peristaltic movement" depending on the alternating action of the longitudinal and circular muscular coats of these organs. He pronounces our views in regard to the physiology of the uterus during pregnancy and during the puerperal state as well as the pathological relations governing a rupture of the uterus erroneous.

Werboff criticizes the theory of Bandl, that a thinning out of the lower uterine segment is the cause of rupture, and places the fault in the friability of the tissue as a result either of difficult previous births or else as an acute developing condition in the first pregnancy. Coincident with this friability, there is a functional weakness of the uterine musculature, the clinical picture of a rupture varying according to either one or both of these pathological conditions. According to the author, there can be no prophylaxis, as the symptoms heretofore called "threatened rupture" are in reality due to a "beginning rupture." A detailed contradiction to the anatomic basis of the Bandl theory is offered, the author applying his own law of peristaltic movement to all of the uterine functions incident to labor and the puerperium, and to the changes in form resulting therefrom. He differentiates the action of the longitudinal muscular layer from that of the circular, the former producing complete effacement and dilatation of the cervix, and the latter, aided by the thoracic-abdominal pressure, serving to expel the child.

In the antagonistic action of the abdominal muscles and diaphragm the upper fixed point of support for the contracting uterus is really to be found within the lungs. The contractions and expansions of the lungs and the changes in form incident thereto are the origin of the voluntary pressure pains, i.e., the contractions of the supporting muscles of the thoracic and abdominal cavities. Special significance is attached to the anterior abdominal muscles as being the anterior fixed points for the uterus to work against. During an insufficiency of these muscles the woman in labor endeavors to overcome the disturbance of the pressure pains resulting therefrom by assuming various positions most favorable to her.

The author recommends, as a practical aid in cases where an insufficiency exists, that a suitable binder be applied during the expulsion period by the woman herself and in a manner most effective to her. In severe diastasis of the recti with the so-called "Hängeleib," the correction of the position or stretching of the contracted anterior wall of the uterus would be too painful, and therefore the application of the binder is contra-indicated. The author

has employed the binder in 123 cases, with very favorable results. The monograph closes with a complete contradiction of the Bandl theory as to effacement of the lower uterine segment even though in many points a definite proof of his contention is still lacking. The article contains plates of Bandl's own work, and autopsy protocols of the author's four cases of ruptured uterus.

VASSNER.

ADNEXAL AND PERIUTERINE CONDITIONS

Cohn, F.: The Clinical Significance of Rupture of the Follicle in the Ovary (Die klinische Bedeutung der Follikelsprungstellen im Ovarium). *Arch. f. Gynäk.*, 1913, xcix, 505.

By Zentralbl. f. d. ges. Gynäk. u. Geburtsh. s. d. Grenzgeb.

In the rupture of a graafian follicle, the peritoneal cavity communicates with the inner part of the ovary for a time at the site of the rupture. The layer of lutein cells which form over the site of rupture is very thin and is often further thinned out by the accumulation of fluid in the space. This new cyst also may rupture and hæmorrhage may follow. Bacteria from the abdominal cavity may enter into the ovary at this site.

Hæmorrhage from a follicle has its origin either in a torn vessel or in deeper-lying ovarian tissue. Schauta has observed a follicular hæmorrhage of several liters of blood. Hæmorrhage into the free peritoneal cavity from a corpus luteum occurs nearly as often. Bürger described such a case where more than two liters of blood were lost. Cohn adds six cases of his own to those already published. In five instances the severe hæmorrhage came from a fully developed, and in one instance, from a retrogressive, corpus luteum. In two cases ruptured tubal pregnancy was suspected; in the other four cases it was found incidentally. The hæmorrhage in two cases was due to pressure on the matured follicle during an internal examination. Hæmorrhages of this kind may be controlled with mattress sutures or by excising the part. Large follicular hæmorrhages can always be recognized at operation; smaller intraperitoneal hæmatocèles may be present without symptoms, and are found only incidentally. The hæmorrhages may be followed by adhesions between the adnexa and the peritoneum.

That bacteria migrate into the follicles has also been demonstrated. The frequently occurring corpus luteum abscesses are due usually to gonococci or tubercle bacilli, and but rarely to streptococci, staphylococci or pneumococci. In a case recorded by Orthmann the fimbriated extremity of the tuberculous tube extended directly into the corpus luteum abscess. Frys found an ascaris in an abscess of this kind.

Fraenkel, Orthmann and Menge state that tubal diseases in particular are apt to cause an infection of the follicle and corpus luteum. The bacillus coli and anærobic organisms play a minor rôle. The ruptured follicle and corpus luteum may be penetrated also by cellular elements, such as carcinoma cells.

VON MILTNER.

Von Franqué: Cure of an Ovarian Cancer with Metastases by Operation and Subsequent X-Ray Treatment (Heilung eines Ovarialcarcinoms mit Metastasenbildung durch Operation mit nachfolgender Röntgenbestrahlung). *Deutsche Gesellsch. f. Gynäk.*, Halle, 1913, May.

By Zentralbl. f. d. ges. Gynäk. u. Geburtsh. s. d. Grenzgeb.

In a patient, 16 years old, an ovarian cancer the size of a head, which penetrated deeply into the broad ligament, was removed on April 12, 1912. A retroperitoneal metastasis the size of a fist and numerous lymph gland metastases had to be left behind. The after-treatment consisted of X-raying with five erythema doses during three months, with the result that the palpable metastases disappeared. The patient has remained free from any recurrence for one year and must be considered completely cured. On microscopical examination the tumor showed the characteristics of severe malignancy; well-marked mitosis, polynuclear cells, syncytial formations and sarcomatous degeneration of the stroma.

Steinharter: Endothelioma of the Ovary, with Report of a Case of Mesothelioma of the Ovary. *Lancet-Clin.*, 1913, cx, 84.

By Surg., Gynec. & Obst.

The author discusses the classification of this condition, calling attention to the difficulty and confusion in the classification and nomenclature of similar tumors of the ovary. He believes that in no case reported has it been proven that the tumor had its origin from the endothelium of blood vessels. As all the tissues of the ovary are evidently of mesenchymal origin, he would classify these tumors as mesotheliomata unless a definite relation to the vascular endothelium can be established.

The author reports a case, giving a brief history, the autopsy findings, microscopical description, and four excellent microphotographs. C. H. DAVIS.

Seeligmann, L.: A Successful and Combined Method of Biochemic and X-Ray Treatment of Malignant Tumors; the Cure of a Recurrent Ovarian Sarcoma with Metastasis in the Spinal Column (Über eine erfolgreiche, kombinierte Methode der Chemo- und Röntgentherapie maligner Tumoren; ein schweres Rezidiv eines Ovarial-Sarkoms mit Metastase in der Wirbelsäule geheilt). *Deutsche Gesellsch. f. Gynäk.*, Halle, 1913, May.

By Zentralbl. f. d. ges. Chir. u. i. Grenzgeb.

The use of the X-ray combined with mesothorium emanations is only a local treatment which is confined to the upper layers of the new growth. It does not act upon the more deeply situated parts of the cancer and the metastases. If the present views as to the cause of cancer are considered, a combined treatment, constitutional as well as local, must be instituted. By such treatment it is possible to so weaken the vitality of the advancing epithelial cells in the tissues that they will succumb to the destructive action of the X-rays.

Also on the basis of the other theory, which is advocated by Czerny, i. e., that a parasite is the

etiological factor of cancer, the combined treatment is the best. It is possible that the parasite might be killed by the intravenous injection of arsacetin just as the spirocheta pallida is overcome by salvarsan. After the destruction of the parasite or its toxins, the neoplasm can be resorbed by the X-ray.

The author has used the combined method successfully in a case of pronounced recurrence of an ovarian sarcoma with metastases in the spinal column. The tumor disappeared entirely and the metastases in the spinal column were completely cured. The bad effects attributed to the use of arsacetin can be avoided by using it in small doses and testing the sense of color every eight to ten days. Existing diseases of the eyes are a contra-indication to the use of the drug.

Öhman: Ovarian Hæmatoma and Ovarian Hæmorrhage (Ovarioverenvuodoista ja ovariohematomeista). *Duodecim*, 1913, xxix, 55.

By Zentralbl. f. d. ges. Gynäk. u. Geburtsh. s. d. Grenzgeb.

Six cases of ovarian hæmorrhages are reported. The cases were treated during the last year and discovered during the course of the operation. In two cases the operation was performed for suspected extra-uterine pregnancy; in one the ovarian hæmorrhage was found associated with uterine myoma; in another case an ovarian tumor was diagnosed; in the fifth the diagnosis was uncertain and an exploratory laparotomy was performed; and in the sixth case a chronic appendicitis was diagnosed. Five of the operations were performed by the author. All the six patients recovered. Five times a hæmatoma had formed and in one case the hæmorrhage was just beginning and was most profuse in the region of the follicles. Each case was examined microscopically. Corpus luteum hæmatomata were found three times. In two cases a large hæmatoma had formed in the middle of the ovarian stroma. Inflammatory processes were not present within the ovaries but an acute pyosalpinx was found in one case and a chronic pyosalpinx in another. In the other four cases both tubes were perfectly healthy.

Ovarian hæmorrhages may be classified as follows: 1. Diffuse hæmorrhages confined mostly to a follicle and its immediate surroundings without the formation of a hæmatoma. 2. Hæmatoma formation in the ovarian stroma. 3. Corpus luteum hæmatoma with distinctly demonstrable lutein cells.

Surgical treatment is the best, as conservative treatment is protracted and hard on the patient. During appendectomies, especially if the appendix appears healthy, attention should be given to the ovaries to discover hæmorrhages or hæmatomata. Causative etiological factors could not be found in these cases. BJÖRKENHEIM.

Stetten: A Method of Ventrofixation Combined with Certain Tubal Sterilization by Means of Extra-Abdominal Displacement. *Surg., Gynec. & Obst.*, 1913, xvii, 120. By Surg., Gynec. & Obst.

The author describes a method of ventrofixation combined with certain tubal sterilization. He

points out the uncertainty and complexity of the various plans suggested for tubal sterilization and emphasizes the fact that the prevention of a future pregnancy without castration is frequently indicated in the more advanced prolapse of younger women. For such cases he recommends the combined operation, the essential features of which are as follows: Through a median laparotomy the round ligaments are ligated about two inches from the uterus, divided proximal to the ligatures, and freed from the broad ligaments to the uterine cornua by a few snips of the scissors. The peritoneal edges of the incisions in the broad ligaments are sutured. Ligatures are then passed between the tubes and the ovaries and the tubes are freed to the uterine attachments. The freed round ligaments and tubes are then brought through a stab-wound of the fascia, muscle, and peritoneum. They are drawn taut and fixed with a suture to the fascia. A stitch through the scarified fundus of the uterus is included in the peritoneal suture. The muscle and fascia are closed in the usual manner.

For more absolute fixation one or two of the fascial sutures may be passed through the uterus, the peritoneum having been left open. The excess of tubes and round ligaments is removed. The tubes are ligated and the stumps cauterized. The tubes and ligaments should be left long enough to overlap in the median line. They are then stitched to the fascia and to the structures of the opposite side. The skin is closed. The round ligament fixation part of the operation is practically the method advocated by McKay. The drawing of the tubes through the stab-wound has the double object of reinforcing the fixation and producing a certain sterility.

The author finally suggests that this lodgment of the distal ends of the tubes outside of the abdominal cavity might be used for the purpose of producing temporary sterility.

Blumberg: A New Operation for the Sterilization of Woman with a Future Possibility of Restoring the Function (Neue Operation zur Sterilisierung des Weibes mit Möglichkeit der späteren Wiederherstellung der Fruchtbarkeit). *Berl. klin. Wchnschr.*, 1913, I, 729.

By Zentralbl. f. d. ges. Gynäk. u. Geburtsh. s. d. Grenzgeb.

For the purpose of sterilization each ovary should be put into a pouch or pocket made of peritoneum between the broad ligament and the posterior surface of the uterus, so that no ovum can enter the tubes which remain untouched. The free edge of the broad ligament is folded onto the posterior surface of the uterus, and the ovary placed into this pocket. The free edge is then sutured carefully to the uterus so that it becomes impossible for an ovum to escape. It is usually advisable in making the pocket to anchor the ovary with a temporary retention suture of catgut through the lig. ovarii; also to reinforce the suture line by painting it with tincture of iodine so that no loopholes remain.

The restoration of function could be accomplished very easily by a later opening of the pocket with liberation of the ovary. The author has performed the operation vaginally in six cases during the past two years, with complete success as far as sterilization is concerned. He has not had occasion to restore the function.

BUTZENGEIGER.

Funk-Brentano and Plauchu: The Treatment of Sterility in Woman (Trattamento della sterilità nella donna). *Riv. internaz. di clin. e terap.*, 1913, viii, 81.

By Zentralbl. f. d. ges. Gynäk. u. Geburtsh. s. d. Grenzgeb.

The chief cause of sterility in the female is gonorrhoea. Primary sterility on account of disease or general conditions is difficult to investigate. Sterility due to congenital or acquired malformations of the vulva is cured by incisions or other operative procedures. Changes in the development of the uterus have but little influence if the development of the ovum is normal. Infantilism is curable by electricity, massage, and dilatation. Stenoses of the cervical canal of whatever origin, accompanied by marked flexion of the uterus, must be dilated repeatedly, and for a long period of time. The large number of operations devised for this trouble have resulted usually in failure. Malpositions are important causes of sterility, and if correction is not obtained by means of manual replacement or pessary, an intra-abdominal shortening of the round ligament is advised.

Tumors of the uterus, such as myomata, are unfavorable. The author favors removing them by enucleation. Malformations of the adnexæ are much less important than gonorrhoeal changes; therefore surgical treatment is frequently indicated, and conservatism is necessary. As secondary sterility, the author considers those cases that have been pregnant once. Thirty per cent of all sterility cases are of this kind and are usually the result of gonorrhoea. More rarely they result from puerperal infection.

BERBERICH.

Hertzler, A. E.: "Pericolic Membrane" of the Broad Ligament. *Surg., Gynec. & Obst.*, 1913, xvii, 60.

By Surg., Gynec. & Obst.

From both clinical and experimental evidence the author concludes that surgeons have taken too narrow a view of the so-called pericolic membrane. In the broad ligament over a varicose pampiniform plexus may be found an entirely similar structure consisting of a network of subperitoneal vessels, arranged prevalingly parallel from below upward and connected by fine vessels with the plexus beneath. These vessels become empty when the dilated plexus is tied off and removed. In a case re-operated a year after a pampiniform resection, a similar membrane, well marked at the first operation, was found to have wholly disappeared. An analogous formation occurs in the deep layers of the skin of the scrotum in varicocele, when vessels normally invisible have become as large as goose quills.

The author has produced membranes of this kind experimentally. By careful injections of silver nitrate solution the transparent spaces in the mesentery of laboratory animals can be shown to contain minute bloodless channels which dilate and fill with blood in response to stasis or irritation. If a bit of sterile gauze be thrust beneath the peritoneum a typical "pericolic membrane" develops. The pericolic membrane is thus of circulatory origin and is a special case of what the author has called "varicosity of the peritoneum." It is not a developmental anomaly, although it may affect an abnormal peritoneal fold. It does not follow severe crises, but is always due to slight, long-continued disturbances. It is to be distinguished rigidly from pseudo-peritoneal membranes, which result from exudative processes.

Wolff: Rare Distribution of Resorbed Dermoid

Contents (Seltene Verbreitungswege des resorbierten Dermoidinhalts). *Deutsche Gesellsch. f. Gynäk.*, Halle, 1913, May.

By Zentralbl. f. d. ges. Gynäk. u. Geburtsh. s. d. Grenzgeb.

In a case of right-sided ovarian dermoid with extensive resorption of fat into the wall of the cyst and into the broad ligament, there were also three cysts the size of a hazel-nut in the mesenterium of the appendix containing typical dermoid fat contents. The changes in the wall of the tumor were identical with the change occurring in the tumor walls in the cases of resorption of fat described by Schottländer, Krömer, Gentili and others. In the absence of any demonstrable rupture of the cyst wall it is assumed that the transportation of the fat occurred by way of the lymphatics.

EXTERNAL GENITALIA

Legueu: The Transperitoneal, Vesicular Route for the Cure of Certain Operative Vesico-Vaginal Fistulae (De la voie transpéritonéo-vésicale pour la cure de certaines fistules vésico-vaginales opératoires). *Arch. urol. clin. de Necker*, 1913, i, 1.

By Journal de Chirurgie.

The vesico-vaginal fistulae which sometimes follow hysterectomy when the bladder has been injured in the course of the operation are very difficult to treat from below by the usual vaginal route. On the other hand, the upper route is recommended in cases of this kind. The operation is then either transvesical or transperitoneal. Legueu has combined both of these methods in a new operation, transperitoneal-vesicular, which he describes as follows:

1. Median laparotomy is performed below the umbilicus, with opening of the peritoneum and protection of the operative field. Then the posterior bladder wall is opened exactly in the median line, the incision extending into the vagina. The cut edges are held up with forceps and drawn forward towards the pubes until the entire bladder is exposed to its base.

This gives easy access to the fistula which can then be seen through the incision in the bladder.

2. The vagina and bladder are then separated with the scissors until the two structures are as independent as they were before the fistula was formed. This separation of the two walls should be carried at least a centimeter beyond the edge of the fistula.

3. Careful suture of the bladder in two layers.

4. Separate suture of the vagina.

5. Peritonization of the injured surfaces. Legueu recommends slipping the peritoneum over the two structures in such a way as to interpose between them a veritable peritoneal cul-de-sac. He sees no danger in this interposition of peritoneum, but believes that it favors rapid healing, rendering the suture firmer.

6. Closure of the abdominal wall, leaving a drain in the peritoneal cul-de-sac.

Legueu used this method in the case of a patient who had had a hysterectomy 3½ months before, developing a fistula at the base of the vagina which could be easily seen by cystoscopy and which was situated between the two ureteral orifices. The patient lost urine constantly day and night, evacuation taking place both by the urethra and the vagina. Following the operation there was some abdominal reaction with tympanites but this ceased after a purgative on the third day. The vesical catheter was removed on the tenth day. At the time of leaving the hospital, the 25th day, the patient urinated every three hours only. There was a slight escape through the vagina, but it occurred at night only and in such small quantities that the author felt justified in concluding that his procedure had been successful.

MAURICE CHEVASSU.

Heymann, H., and Moos, S.: Experiences with the Vaccine Treatment of Gonorrhoea in the Female (Erfahrungen über Vaccinebehandlung der weiblichen Gonorrhoe). *Monatschr. f. Geburtsh. u. Gynäk.*, 1913, xxxvii, 623.

By Zentralbl. f. d. ges. Gynäk. u. Geburtsh. s. d. Grenzgeb.

Heymann and Moos employed arthigon in ninety-one cases for diagnostic purposes, and in fifty-nine cases for treatment. For diagnosis .5 ccm. given subcutaneously was not reliable. Of twenty-one uncomplicated cases of gonorrhoea, a local reaction was obtained thirteen times and a general reaction once; forty-five cases with complications (mostly adnexal disease) rendered a local reaction thirty-two times, and a focal reaction seven times; seventeen times a slight temperature rise occurred. In thirteen cases of fresh ascending infections no reaction was obtained.

Very decided positive reactions were obtained also in non-gonorrhoeal conditions: in one case of tuberculosis of the adnexa, in two cases of appendicitis with secondary adnexal disease, in one case of tubal abortion and in one case of ovarian cancer, all diagnoses being confirmed by operative findings.

In fifty-nine cases arthigon was employed exactly

according to Bruck's directions. Injurious results were never observed; a local reaction only rarely; focal reactions several times, but in most cases only on administration of larger doses; general reactions were obtained most frequently. Only fifteen cases remained without fever; all others had temperature rises from a few tenths of a degree to over forty degrees; the general condition remained uninfluenced. In contradiction of Bruck's claims, the temperature reaction is no criterion of the end result obtained.

The results observed in fresh open cases (urethral and cervix gonorrhœa) were absolutely negative in adults. Vulvo-vaginitis in children was not treated. Older adnexal disease was scarcely influenced, nine cases showing slight improvement and seven none. Better results, however, were obtained in acute ascending adnexal disease; absolute cure in 10 per cent of the cases, decided improvement in 27 per cent, slight improvement in 41 per cent and in 20 per cent none whatever. The subjective improvement in 23 patients was good, in 14 slight. There was no improvement in 16.

Most decided improvement occurred in joint complications: excellent in two cases, marked in three, and no improvement only once. In this class of cases the improvement was much more rapid than could be obtained by other methods. From these results it can be seen that the vaccine treatment offers no better results than the former conservative methods. The combination of both methods would probably give the best results. BISCHOFF.

MISCELLANEOUS

Weitzel: X-Ray Therapy (Röntgentiefen-Therapie). *Deutsche Gesellsch. f. Gynäk.*, Halle, 1913, May.
By Zentralbl. f. d. ges. Gynäk. u. Geburtsh. s. d. Grenzgeb.

The technique for X-ray treatment is minutely described. The author rays through 8 different places, using a tube 7 to 9 Benoist-Walker, and a diameter of 7 cm., with 4 to 5 milliamperes per second, an aluminum filter of 3 mm., and a focal distance of 18 cm. Two séances of 4 exposures each on two succeeding days form one series. The dose is measured by the Kienböck method and amounts to 80 x per series. The rays are applied only through the anterior wall. Twenty out of twenty-one cases of myomata became amenorrhœic. In one case the myoma grew, necessitating its removal. The tumor was not malignant. Amenorrhœa was obtained in 2.1 months on an average. The age of the patient has no influence on the time. For a full course of treatment 500 to 600 x=7 series were required. It is continued until the menses have remained absent for 8 weeks. A decrease in the size of the tumor occurred in 15 cases, twice from the size of a man's head to that of a fist or goose egg. The symptoms disappeared in 5 cases, while the tumor remained unchanged. In 5 cases of metropathia hæmorrhagica, amenorrhœa resulted on an average in 1.4 months;

250 to 300 x=3 to 4 series were required for a complete cure. In half of all the cases, symptoms of climax appeared. Disturbances of the bladder or bowel were not observed.

If wrong diagnoses can be avoided, if patients with irregular hæmorrhages are subjected to a diagnostic curettage before the beginning of the X-ray treatment, and if the patients are continuously kept under careful supervision during the treatment, then a complete cure in a clinical sense may be obtained by the X-ray treatment in cases of myomata and hæmorrhagic metropathia without danger to the patient.

Füth: X-Ray Treatment in Gynecology (Röntgentherapie in der Gynäkologie). *Deutsche Gesellsch. f. Gynäk.*, Halle, 1913, May.
By Zentralbl. f. d. ges. Gynäk. u. Geburtsh. s. d. Grenzgeb.

Füth describes the application of the X-rays as used by Graessner in the Cologne Academy and the complications which he observed in 41 cases treated by the rays. As such, he mentions frequent desire to urinate, nausea, vomiting and pigmentations of the skin. The results of treatment are as follows: In metropathia, 11 per cent were improved and 89 per cent cured; in myomata, 15 per cent unimproved, 5 per cent improved and 80 per cent cured. Two cases each of myomata and metropathia began to bleed again, necessitating further rayings. Four cases of myomata treated by the rays were afterwards for various reasons treated surgically. In metropathia a curettage should precede the raying to avoid a hæmorrhage at the first menstrual period following the commencement of the treatment.

Nausea and vomiting are probably caused by the inhalation of the ozone produced during the treatment. It is intended to decompose the gas by catalytic methods before it is inhaled.

Runge: X-Ray Treatment in Gynecology (Röntgentherapie in der Gynäkologie). *Deutsche Gesellsch. f. Gynäk.*, Halle, 1913, May.
By Zentralbl. f. d. ges. Gynäk. u. Geburtsh. s. d. Grenzgeb.

Of 29 cases of metropathia, 25, or 86 per cent, became amenorrhœic and 4 were subsequently operated. Of 90 cases of myomata, 86, or 95 per cent, became amenorrhœic and 4 were operated. The cause of the negative result could not be determined but was probably due to a submucous location of the tumors. A decrease in the size of the tumors was noticed in about 40 per cent of the cases in which amenorrhœa was produced. The result in 10 cases of pruritus vulvæ were very good and in 7 cases of dysmenorrhœa doubtful, about 43 per cent of the latter being cured. The raying of two cases of adnexal inflammations resulted at first in profuse menstrual bleedings but finally in amenorrhœa.

The symptoms of change of life are not any more severe than those of the normal physiological climax. The author finally reports the immediate accessory symptoms produced by the raying and describes the technique. On an average, 3 to 4 series are neces-

sary in metropathia, and 5 to 6 in myomata, for the production of an amenorrhœa.

Heimann: X-Ray Treatment (Röntgentherapie). *Deutsche Gesellsch. f. Gynäk.*, Halle, 1913, May. By Zentralbl. f. d. ges. Gynäk. u. Geburtsh. s. d. Grenzgeb.

This is a report of gynecological X-ray treatment at the Breslau clinic. Myomata, uterine hæmorrhages and inoperable, as well as postoperative, cases of cancers were treated. The time elapsed since the raying of the latter is too short to permit the issuing of a report. Forty cases of myomata and metropathia hæmorrhagica have been treated, and with the exception of one case, all were cured. In the great majority of the cases an amenorrhœa was produced, and in a few cases only an oligomenorrhœa. In the unimproved case, a suspicion of malignancy arose during the treatment and the latter was stopped on that account. Finally a description of the technique is given.

Fellner, O. O.: Experimental Contributions to the Physiology of the Female Genitalia (Experimentelle Beiträge zur Physiologie der weiblichen Genitalorgane). *Deutsche Gesellsch. f. Gynäk.*, Halle, 1913, May.

By Zentralbl. f. d. ges. Gynäk. u. Geburtsh. s. d. Grenzgeb.

Fellner injected a large number of sexually immature rabbits and guinea pigs with alcoholic ethereal extracts of placenta, ovary and uterus. The injections, which were in part subcutaneous and in part intraperitoneal, were carried out over a long period of time.

Laparotomy and sections showed that a marked hypertrophy of the uterus resulted. The muscular layer was hypertrophied, the mucosa decidedly thicker and higher; the epithelium, normally flat, grew higher and cylindrical, and became dotted with vertical nuclei. The vagina became larger and wider, the epithelium assumed the characteristics of the epithelium in pregnancy. The mammary gland enlarged to four or five times its normal size.

Very similar results were obtained also with the male animals. The suprarenals were greatly hypertrophied; the kidneys showed a parenchymatous nephritis with much albumen excretion. Even when placental extract from the same species was used, similar but much less marked findings occurred. The same results were obtained with preliminary castration before injection.

The substance used is soluble in salt solution, 70 per cent alcohol and ether. It is thermostable and therefore can be sterilized completely. Similar results were obtained with extracts of the amniotic membranes. Much weaker in effect were the results following injections of alcohol-ether extracts of corpus luteum taken from the ovaries of non-pregnant cows. The same effect was obtained with alcohol-ether extracts of ovaries of pregnant cows, whereas similar extracts of the uterus of pregnant animals gave only slight reaction, and those of the uterus

of non-pregnant animals and of ovaries not containing a corpus luteum of non-pregnant animals gave none at all. Extracts of testicles produced the same results as the extracts of the ovaries, whereas brain extract produced none at all. If cholesterin and cholesterin esters are removed from the extract the effect of the extract is not altered. As to whether we are dealing with an internal secretion of the placenta, the author is unable to decide at the present time.

Newman: Cases Illustrating Certain Urinary Conditions in Women Associated with Frequent or Painful Micturition. *Clin. J.*, 1913, xlii, 193. By Surg., Gynec. & Obst.

Newman gives a very interesting discussion of the most important urinary disturbances in women.

Cystitis of pregnancy, with its results. This form of inflammation of the bladder is often overlooked at its onset as the symptoms are attributed by the patient to "her condition." Another danger arises from the early disappearance of acute symptoms in many cases, and care is not taken to free the bladder from infective organisms. These patients suffer from inflammation of the bladder and the neck of the urethra. The author irrigates with boric acid solution twice daily, and after a week has swabbed the urethra with pure phenol, and afterward with an alkali to stop the action of the acid. Cocaine bougies are introduced to relieve pain.

Early renal tuberculosis is often not accompanied by pain; frequent micturition or nocturnal incontinence are the only symptoms. Vesical irritability, and, after a time, pain, also become features. When the kidney is normal, the orifice of the ureter is also normal, and when one ureteral orifice is normal while the other is altered, the renal lesion is on the side of the morbid ureter.

In early tuberculosis of the bladder the most characteristic changes are hyperæmia of the floor and neck of the bladder, associated with minute nodules beneath the epithelium of the mucous membrane of the bladder. The author reports a case in which he curetted the caseous deposit on the floor of the bladder through the urethra. The patient was also treated with tuberculin R.

Lesions at the neck of the bladder, the trigone, and the urethra cause frequency of urination and often incontinence. He reports a case in which he twice applied his phenol treatment. In other cases his treatment consisted of irrigation with the permanganate and chlorate of potassium and the instillation of a weak silica solution. In a severe staphylococcus infection of the bladder he employed suprapubic drainage and irrigated with boracic acid and filtrate of saurine (lactic acid cultures).

Minute polypi in the urethra are rare, but may cause considerable irritation. They may be removed with curette or snare.

A case is reported in which a movable right kidney caused severe pain at the end of micturition. It was cured by nephrorrhaphy. C. H. DAVIS.

Bauereisen, A.: The Atria of Post-Operative Infection of the Female Urinary Tract (Über die Ausbreitungswege der postoperativen Infektion in den weiblichen harnorganen). *Ztschr. f. gynäk. Urol.*, Leipz., 1913, iv, 1.
By Zentralbl. f. d. ges. Gynäk. u. Geburtsh. s. d. Grenzgeb.

After thorough microscopical investigations the author comes to the following conclusions: The chief source of infection for the urinary bladder is the urethra, from which organisms reach the bladder either as a result of catheterization or of spontaneous ascending infection. These lead to an inflammation of lesions produced during the operation. The migration of organisms from the outside of the bladder through the bladder wall occurs only rarely, and then only in severe infections of the surrounding tissue. When it does occur, however, the organisms are rapidly walled off by infiltration and granulations as well as by the lymph stream which runs in the opposite direction. The same conditions hold in cases of infection of the ureters. The kidneys are infected either from a hæmatogenous source or through the spontaneous ascension of organisms from the bladder.

The principal kinds of bacteria involved are the staphylococci, streptococci, and the colon bacillus, the latter usually in combination with pyogenic cocci. Avoidance of catheterization is advised wherever possible. The preferred therapy is the prophylactic injection of boroglycerin and pituitary extract. In those cases in which the catheter is indispensable, irrigation with collargol should be resorted to as soon as a cystitis begins to develop.
HAGEN.

Mayer, A.: The Use of Serum in Obstetrics and Gynecology (Über die Serumanwendung in der Geburtshilfe und Gynækologie). *Med. Cor.-Bl. d. württemb. ärztl. Landesver.*, 1913, xviii, 261.
By Zentralbl. f. d. ges. Gynäk. u. Geburtsh. s. d. Grenzgeb.

By means of a series of successfully treated cases of dermatitis, herpes, urticaria, etc., the author proves the correctness of his proposal to treat the toxæmias of pregnancy with the blood serum of healthy pregnant women. If the result is negative there must be an accidental dermatitis present or the serum injected is not normal. In the latter case serum from another pregnant woman must be employed. Hyperæmesis gravidarum, nephritis of pregnancy, icterus and eclampsia are favorably influenced, the latter especially by epidural injections. Eclampsia is rare in Württemberg, but in the few cases treated the results were so striking and rapid that they offered considerable encouragement for further investigations. The same is true of eclampsia neonatorum.

The author examined the serum of puerperal women who, in spite of the fact that they had hæmolytic streptococci in their blood, remained perfectly well throughout the entire course. He describes the three following cases: 1. Severe general sepsis. After two injections decided improvement was

noted. The associated peritonitis, however, could not be checked. 2. Sepsis with diarrhœa. The patient had received two injections of serum from a convalescing puerperal sepsis case when improvement set in. 3. Collæmia with diarrhœa and exanthem. This patient was given serum from a patient who had a bacillus coli pyelitis. Improvement occurred also in this case. In all of the cases immediate improvement occurred in the general condition of the patients, with decrease in temperature and pulse, cessation of diarrhœa, etc. In pyæmia the serum apparently is not of much value, as it cannot attack the organisms within the thrombi. Pregnancy serum was tried also in severe anæmia, chlorosis, and especially in anæmia due to bleeding fibroids; in the latter cases it tided the patients over until operation could be performed. LAUBENBURG.

Mayer, A.: The Significance of Infantilism in Obstetrics and Gynecology (Die Bedeutung des Infantilismus in Geburtshilfe und Gynækologie). *Deutsche Gesellsch. f. Gynäk.*, Halle, 1913, May.
By Zentralbl. f. d. ges. Gynäk. u. Geburtsh. s. d. Grenzgeb.

In infantilism the first menstrual period is often delayed. The women are often and wrongly thought to be genitally diseased and are treated gynecologically without benefit. Menstruation is frequently associated with dysmenorrhœa so that the working capacity is disturbed. In marriage, lessened sexual desire and dyspareunia lead to a true martyrdom and the marriage often remains childless. If conception results abortion frequently follows. The disturbances of pregnancy are often increased, all possible but harmless abnormalities being treated for this in vain. During labor, weak pains, rigidity of the cervix, decreased relaxability of the soft parts, narrow pelvis, etc., indicate mechanical hindrance, laceration of the soft parts, and infection.

Resistance to infection is lessened on account of the hypoplastic condition of the circulatory system. For the same reason anæsthetics are especially dangerous in such cases. The ability to nurse is usually defective. The poorly developed perineum has a predisposition to prolapsus, but the retroflexio uteri which is frequently observed is not the cause of the patient's numerous complaints. Treatment for it is unnecessary and often disadvantageous. A tortuous tube predisposes to extrauterine pregnancy. A deep cul-de-sac may cause diagnostic difficulties in intra- or extraperitoneal rupture of tumors.

When infantile stigmata are associated with inflammatory adnexal disease of doubtful origin tuberculosis may possibly be the etiological factor; when associated with ovarian tumors we may suspect embryomata, and when tumors are present in the pelvis, a displacement of the kidney into the pelvis should be thought of. Infantile women are congenital invalids, often simulating gynecological disturbance without being genitally diseased.

SCHMITZ.

OBSTETRICS

PREGNANCY AND ITS COMPLICATIONS

Markoe and Wing: The Thyroid in Pregnancy.

Bull. Lying-In Hosp., N. Y., 1913, ix, 96.

By Surg., Gynec. & Obst.

After examining 601 cases the authors conclude that the relation of the thyroid to the physiology and pathology of pregnancy shows a diversity in its clinical manifestations which is puzzling and difficult to analyze. The symptoms of hyperthyroidism developing during pregnancy usually show a decided diminution after confinement, and with succeeding pregnancies the symptoms are not so severe. The management of pregnant cases showing thyroid enlargement, with or without hyperthyroidism, is directed toward:

1. Open air treatment and the improvement of the hygienic surroundings.
2. Avoidance of nervous strain and worry.
3. Maximum of sleep and rest.
4. Simple diet and regulation of the bowels.
5. Tonic medication.
6. In some cases administration of the syrup of hydriodic acid.

In cases in which the symptoms are severe, the authors advise absolute rest in bed.

ROBERT T. GILLMORE.

Landsberg: The Significance of the Ductless Glands for Metabolism During Pregnancy

(Die Bedeutung der innersekretorischen Drüsen für den Stoffwechsel in der Schwangerschaft). *Deutsche Gesellschaft. f. Gynäk.*, Halle, 1913, May.

By Zentralbl. f. d. ges. Gynäk. u. Geburtsh. s. d. Grenzgeb.

The ovaries and thyroid gland were extirpated in pregnant bitches and the metabolism of hunger was studied before and after the operations. It was found that in comparison to normal conditions a slight increase in the protein metabolism occurred during pregnancy after oöphorectomy. A decrease in the nitrogen excretion was observed after the injection of an extract of the true corpus luteum. The decrease in the nitrogen excretion was not so marked after thyroidectomy in the pregnant compared with the non-pregnant. The hyperplasia of the thyroid in pregnancy should not be construed as causing a hyperfunction in metabolism. This also explains the retarded metabolism after oöphorectomy. The thyroid gland was removed in two cases in which pregnancy continued to exist for some time after oöphorectomy. A surprising decrease of the thyroid gland after a preceding oöphorectomy was found. Marked differences were also seen on microscopical examination. Metabolism was more decreased than after thyroidectomy.

Examinations of the phosphorus and calcium excretions were undertaken but the results obtained so far do not permit us to draw a conclusion. Further investigations will be made. The investigations made so far permit the statement that the function of the ductless glands during pregnancy shows important differences from that during the non-pregnant condition.

Horsley, J. S.: Abdominal Pregnancy with Living Child.

Surg., Gynec. & Obst., 1913, xvii, 58.

By Surg., Gynec. & Obst.

Horsley reviews the literature on abdominal pregnancy with living child, and records, with his own case, one hundred and five others. There are six instances in which the mother recovered and the child and the mother were living and in good health a year after the operation. In his own case, which was one of these six, the pregnancy was apparently at full term. The woman had been in labor for some time and was exhausted. Her pulse was 140. The child and placenta were enveloped in a thin membrane which derived its nutrition from the left broad ligament. The uterus was about twice its normal size. The child was delivered and the thin sac and the placenta were removed. The patient and child made a satisfactory recovery and both were living and well more than a year after the operation.

Schewachoff, S. W.: Cardiac Changes During Pregnancy

(Zur Frage der Veränderung des Herzens während der Schwangerschaft). *Arb. a. d. geburtsh. -gynäk. Klin. Prof. Redlich*, St. Petersburg, 1913, i, 3.

By Zentralbl. f. d. ges. Gynäk. u. Geburtsh. s. d. Grenzgeb.

The author examined the size of the heart in puerperæ on different days (1-10 apart) by means of Röntgen rays and also by means of teleröntgenography (focal distance 2 m.). He used a Bauer tube. In order to bring the anticathode against the middle of the heart each time, employing the same central rays each time, a special attachment was constructed. Exposures were made during the middle phase of respiration and when the stomach was empty. The patient was placed horizontally in bed. The time of exposure was not less than two seconds in order that the exposure might be made during the diastole. The measuring technique is described in detail.

From the data in the table that accompanies the original article it is evident that the size of the heart, and the influence of age, size, weight and number of births were different in all of the ten cases examined. In nine cases the heart did not de-

crease in size during the puerperium. In one case in which there was vitium cordis a decrease of the cardiac area up to 1 cm. occurred. From his observations the author concludes that the normal heart does not become enlarged during pregnancy, and is not dilated. As to whether there is a minimal hypertrophy, the microscope alone can tell.

BRAUDE.

Walthard: The Relations of Cardiac Disease to Pregnancy, Labor, and Puerperium (Die Beziehungen der Erkrankungen des Herzens zu Schwangerschaft, Geburt und Wochenbett). *Deutsche Gesellschaft. f. Gynäk.*, Halle, 1913, May.

By Zentralbl. f. d. ges. Gynäk. u. Geburtsh. s. d. Grenzgeb.

Considering the high degree of certainty with which an aortic aneurism is recognized by means of the orthodiagram, the author feels justified in discussing the relations of cardiac disease to pregnancy, labor and puerperium, especially aortitis luetica and its result,—aneurism of the aorta. Among the 35 cases of valvular defects which were observed in the past two years during pregnancy, labor and puerperium there were five which presented the picture of an aortic insufficiency. In three the ortodiagram revealed a broader aortic shadow; two of the latter showed a left-sided recurrent laryngeal paresis with hoarseness. Two of these patients gave a positive Wassermann. In two patients clinical findings of aortic insufficiency were present. In the third case the luetic change involved principally the arch and descending aorta (autopsy report) and the aorta was dilated to a saccular aneurism. The clinical findings elicited by percussion and auscultation were, however, much less marked.

The course of the pregnancy and labor was different in the three cases. In the case in which the aortic shadow was narrowest and in which no pressure symptoms or nerve irritation existed, no cardiac disturbances set in during the entire pregnancy until a few hours before delivery. Dyspnoea made its appearance 15 hours before delivery, and for that reason the patient entered the hospital. Labor and the puerperium, however, went on without any serious disturbance of the circulation. In the second case, in which the widest aortic shadow was present, the patient during the eighth month commenced to complain of severe pains in the back and left side with dyspnoea and cyanosis. In the interest of the child, the patient was treated symptomatically to bring the interruption of pregnancy as near to term as possible. Suddenly rupture of the aneurism and death occurred. Immediate Cæsarean section, however, failed to revive the asphyxiated child. As soon as rupture occurred contractions of the uterus were perceived. In the third case with the medium-sized aortic shadow, pains in the chest, dyspnoea and hoarseness developed in the middle of the last month of pregnancy. As labor set in, dyspnoea, oppression in the chest, and cyanosis became aggravated and as the blood-pressure was about double the normal at the beginning of labor a Cæsarean section was performed under lumbar anæsthesia.

From the literature he concludes that in aneurism of the aorta in pregnancy, rupture of the aneurism usually occurs during the latter half of pregnancy or during labor. It is highly probable that the rise of blood-pressure incident to uterine contractions during pregnancy and labor is the cause of the rupture. The author's conclusions are the following: That a pregnancy in a patient with an aortic aneurism should be terminated by Cæsarean section under lumbar anæsthesia and that sterilization should be performed at the same time.

Gröné: Pregnancy and Labor in Organic Heart Disease (Om havandeskap och förlossning vid organiska hjärtfel). *Allm. Sven. Läkartid.*, Stockholm, 1913, x, 169.

By Zentralbl. f. d. ges. Gynäk. u. Geburtsh. s. d. Grenzgeb.

The author investigated the material of the hospital at Malmö. Fifty-four labors were observed in forty-two women who had cardiac disease, i. e., cardiac insufficiency. Two labors occurred in six women, three labors in one patient and five labors in another. Three died. Fifteen women had mitral insufficiency, 23 mitral stenosis plus mitral insufficiency, 2 aortic insufficiency, and 2 aortal and mitral insufficiencies. In 34 cases compensation was good, in 20 poor; of the latter 6 were near incompensation. The per cent of pregnancy occurring in women with cardiac disease was 1.1 per cent. In 87.5 per cent no disturbance of compensation occurred during pregnancy. Concerning the influence of heart disease, the author concludes that the importance generally ascribed to it as causing spontaneous abortions is largely overestimated. Labor was spontaneous in 31 cases and operative in 14 (forceps 11 times, manual extraction twice, Cæsarean section once). The uterus was emptied 9 times with forceps and dull spoons in abortions. Not once did a severe post-partum hæmorrhage occur.

Nursing should not necessarily be forbidden in these cases. In the literature the author found an average mortality of 1.2 per cent in pregnancies with heart disease. The mortality was 2.6 per cent in cases collected by him. It is not any more dangerous to go through labor with a well compensated valvular disease than under normal conditions. Women suffering from heart disease should be placed under the observation of a physician during the last half of pregnancy. The termination of labor should be left to nature. Interference should be resorted to only in cases where the expulsion is too protracted and the patient is put under great stress by the labor pains.

Profound ether narcosis seems not to be contra-indicated in uncompensated heart disease. Positive indications for the induction of premature labor can hardly be fixed; each case must be treated strictly individually. Premature labor was induced in only one case with a fatal result for mother and child. For the induction of premature labor the author recommends rupture of the sac and pituitrin. In uncompensated cardiac disease, induction can be in

question only in the beginning of pregnancy and then only in multiparæ. The latter cases should also be treated individually. The induction should consist in tamponing the cervix uteri and vagina and, if possible, in rupture of the sac. Evacuation of the uterus is accomplished with abortion forceps and a dull spoon. Finally the author states that the prohibition of marriage is not justifiable in well compensated cardiac disease. In cases of uncompensated cardiac disease, or those which are near the limit of compensation, each and every case should be judged individually.

BJÖRKENHEIM.

Van der Hoeven, P. C. T.: Myoma Operation During Pregnancy. (Myoomoperaties in de zwangerschap). *Nederl. Mandscr. v. verlosk. en Vrouwenz.*, 1913, ii, 285.

By Zentralbl. f. d. ges. Gynäk. u. Geburtsh. s. d. Grenzgeb.

The author gives a short résumé of the operative treatment of fibroids during pregnancy, giving case histories and references to the most important literature on the subject. He then reports three of his own cases in which pregnancy was not interrupted after enucleation of the fibroids and living children were born at term. The prognosis is very favorable for both mother and child.

STRATZ.

Von de Velde: Myoma, Retroflexion, and Pregnancy (Myoom, retroflexie en zwangerschap). *Nederl. Mandscr. v. verlosk. en Vrouwenz.*, 1913, ii, 290.

By Zentralbl. f. d. ges. Gynäk. u. Geburtsh. s. d. Grenzgeb.

The author reports three cases of pregnancy complicated by myomata and retroflexion. In the first case the myoma was situated in the anterior wall of the uterus and was enucleated during the fourth month of pregnancy by laparotomy; abortion followed three days later. There were no further complications. In the second case the myoma was situated in the cul-de-sac of Douglas. The uterus rose out of the pelvis in the course of the pregnancy. Spontaneous delivery of a living child resulted after the tumor had been lifted out of the pelvis bimanually. In the third case the pregnancy was complicated by peritonitic symptoms as the tumor had grown from the posterior uterine wall and was adherent in the cul-de-sac. At term Cæsarean section was performed and a living child delivered. The uterus with the placenta and fibroid was then amputated supravaginally *en masse*. The recovery was uneventful.

STRATZ.

Kosmak: The Diagnosis and Treatment of Eclampsia. *Bull. Lying-In Hosp., N. Y.*, 1913, ix, 129.

By Surg., Gynec. & Obst.

Considerable stress is laid upon the diagnosis of the premonitory signs, as the prophylaxis is of such great importance. Each patient should be warned by the physician of the significance of headache, slight nausea, dizziness, and visual disturbances during the last two months of pregnancy. The author calls particular attention to those cases which have a toxæmia without convulsions.

When the patient is seized with a convulsion he gives immediately $\frac{1}{4}$ grain of morphine followed by the administration of cathartics and enemas together with blood-letting in suitable cases. He warns against the indiscriminate use of chloroform and believes that many deaths have resulted from chloroform poisoning. Diaphoresis is encouraged by wrapping the patient every two or three hours in a blanket rung out of hot water until perspiration is free. In the absence of œdema the blood-stream is diluted by colonic irrigations with normal salt solution, not less than 4 gallons at a time with a temperature of 115° F. Eclampsia comes on between the seventh and ninth month and if labor does not proceed spontaneously, pregnancy should be deliberately terminated without dangerous haste. Where the pulse is of high tension viratrum veride and nitroglycerin are used.

In Kosmak's summary he urges:

1. The certainty of diagnosis.
2. Governing the treatment by the signs and symptoms of each individual case.
3. Conservative sedative and eliminatory measures before radical operative measures.
4. One convulsion should never decide the surgical interference.

ROBERT T. GILLMORE.

Schlossberger, A.: Two Cases of Eclampsia Cured by Means of Hypophyseal Extract (Zwei Fälle von Eklampsie geheilt mit Hypophysenextrakt). *Deutsche med. Wchnschr.*, 1913, xxxix, 1046.

By Zentralbl. f. d. ges. Gynäk. u. Geburtsh. s. d. Grenzgeb.

Case 1. The patient, forty-two years old, was at term in her fifth pregnancy. The cervix was closed and convulsions had been repeated. The urine showed a five per cent albuminuria. 1.1 cc. pituglandol and 0.02 gm. pantopon was injected. Convulsions ceased after one and one half hours and consciousness returned after three hours. A second dose of pituglandol was given. Spontaneous delivery occurred five hours after the first injection. Recovery was complete. Case 2. The patient was twenty-three years old and six months pregnant in her second pregnancy. She was unconscious, having repeated convulsions and anuria. Injections were given as in Case 1. After forty-five minutes the convulsions ceased and diuresis began in three hours. A second injection was given and spontaneous delivery occurred in five hours. The puerperium was normal.

HAPPICH.

Routh, A.: Observations on the Toxæmias of Pregnancy and on Eugenics from the Obstetric Standpoint. *Lancet, Lond.*, 1913, clxxxv, 63.

By Surg., Gynec. & Obst.

The author gives a brief review of the recent work on the toxæmias of pregnancy, serum diagnosis, the relation of the organs of internal secretion and their genital functions, and lactation.

In discussing eugenics from the standpoint of obstetrics he says: "The chief aim of those seeking to endow motherhood should be to give every

mother an assurance of security and well-being during the whole time of pregnancy, labor, and the puerperium, each of which is to her a period of anxiety and stress."

Eugenics should begin before birth, not afterwards. When syphilis is suspected small doses of mercury given during pregnancy often result in a healthy child. "It has been computed that if women were properly examined in pregnancy half the still-born children would be saved."

Routh believes that the registration of births should be compulsory not only after "viability" but also for every period of pregnancy. C. H. DAVIS.

Carr: Cæsarean Section. *W. Va. M. J.*, 1913, viii, 11.
By Surg., Gynec. & Obst.

The author gives a brief history of this operation, and reports that he has performed six Cæsarean sections without a death. Three of his patients had contracted pelvis. In one case where the measurements were carefully taken the true conjugate was 6½ cm. Two patients were girls under sixteen years of age who had been in labor sixteen hours, with only partial descent of the heads, and the cervix partially dilated and rigid. A fibromyoma in the sixth case made a modified Porro operation necessary.

The author believes that with the present low mortality and low morbidity, Cæsarean section should be considered in every case of difficult labor, provided a skillful surgeon and good nurse are to be obtained.
C. H. DAVIS.

Hartmann, K., and Loeschcke, H.: The Uterine Scar Following the Suprasymphyseal Extraperitoneal Cæsarean Section (Die Uterusnarbe nach suprasymphysärem extraperitonealem Kaiserschnitt). *Gynäk. Rundschau*, 1913, vii, 354.

By Zentralbl. f. d. ges. Gynäk. u. Geburtsh. s. d. Grenzgeb.

Hartmann had occasion to extirpate, during the fifth month of pregnancy, a uterus on which he had previously performed two suprasymphyseal Cæsarean sections (the oblique incision of Frank), one incision to the right, and one to the left, of the median line.

At the time of operation the relations were normal, no adhesions of any kind being present. The scars could not be recognized macroscopically; microscopically five connective-tissue strands with intermingling muscle fibres could be seen. In the cervical musculature alongside of the scar there were cystic cavities filled with mucus. These cavities were lined by cervix epithelium and were probably epithelialized stitch canals. Outside of these cavities there was an accumulation of foreign-body giant cells surrounding unabsorbed catgut rests. The anterior wall of the cervix was decidedly thinner than the posterior, due to the bilateral scars.

Hartmann advises employing absorbable suture material and the avoidance of including the mucosa in the stitches. No adhesions will result if primary union occurs and the scars will not weaken in repeated pregnancies.
BAUER.

Van der Hoeven: The Chances for Subsequent Pregnancy after the Classical Cæsarean Section (De kans op zwangerschap na de klassieke sectio caesarea). *Nedere. Mandbl. v. verlosk. en Vrouwenz.*, 1913, ii, 96.

By Zentralbl. f. d. ges. Gynäk. u. Geburtsh. s. d. Grenzgeb.

The author investigated the subsequent history of women who had been subjected to the classical Cæsarean section at the Leyden clinic during the years 1896-1900.

There were 24 cases, one of which died two years after the operation of pulmonary tuberculosis; one could not be found, and five were unmarried. Two of the remaining seventeen had had a subsequent abortion, and only nine of the twenty-four had given birth to children. Six of the latter had delivered one child, one had delivered two, one had delivered three, and the last one had delivered seven children.

The indications for the operation had been narrow pelvis, eclampsia, etc. Six of the seventeen had had a subsequent Cæsarean section; five of the six then remained sterile. The author thinks that intra-abdominal adhesions are the cause of the low fertility of these women, and is in favor of the vaginal (cervical and transperitoneal) section. STRATZ.

Beckmann, W.: Cæsarean Section Performed for Vaginal Stenosis Following an Operation for Vesico-Vaginal Fistula (Kaiserschnitt wegen Scheidenstenose mit vorausgegangener Blasenfisteloperation). *Ztschr. f. gynäk. Urol.*, Leipzig, 1913, iv, 95.

By Zentralbl. f. d. ges. Gynäk. u. Geburtsh. s. d. Grenzgeb.

The author claims that in Russia vaginal stenosis following an operation for vesico-vaginal fistula is quite commonly an indication for Cæsarean section.

A patient, twenty-seven years old, acquired a scar stenosis of the vagina following the first pregnancy. The contraction was situated about the middle of the vaginal canal and a catheter introduced through it entered the bladder. Operation was performed by tearing the scar tissue and suturing the fistula, whereupon a cure was effected. Shortly after, a pregnancy occurred, the patient, however, not entering the clinic until three days after the onset of labor and after rupture of membranes had occurred. The child was dead. The lower part of the vagina was markedly contracted, the lumen being about the size of a lead pencil. The cervix was not palpable. Pulse and temperature were normal. Classical Cæsarean section was performed, and she was delivered of a macerated foetus weighing 3300 gm. A supravaginal amputation of the uterus was performed for the purpose of sterilization. The recovery was uneventful.

BOXER.

Lange: Suprasymphyseal, Cervical Cæsarean Section (Zur Frage des suprasymphysären, cervicalen Kaiserschnittes). *Monatschr. f. Geburtsh. u. Gynäk.*, 1913, xxxvii, 681.

By Zentralbl. f. d. ges. Gynäk. u. Geburtsh. s. d. Grenzgeb.

Lange reports twenty-eight cases treated by this method. He gives also his experiences with it in

forty-two cases of contracted pelvis. The operation was performed transperitoneally (a) in cases where haste was necessary on account of weakness of the foetal heart sounds, (b) in cases where a previous extraperitoneal section had been performed and the presence of firm adhesions was suspected, and (c) in cases which were operated upon shortly after the onset of labor. Otherwise, in twenty-four cases, the extraperitoneal method was employed, but to completion only in eighteen. Of the total number, twenty-six had been examined previously outside of the clinic. In fourteen instances the operation was performed before the membranes had ruptured or within an hour afterward; but in the rest a much longer time intervened, in one case sixty-one hours.

The maternal mortality was very low, only one case dying from sepsis. One of the children was born deeply asphyxiated and could not be resuscitated. No accidental injuries occurred. The number of cases of atony was rather high (13) in spite of the subcutaneous injection of an active ergot preparation shortly before operation. In six cases tamponade of the uterus was necessary; in seven adrenalin injected into the uterine musculature was sufficient. The operation was performed on four women for the second time. In two of these cases the old uterine scar was firm; in the other two it was thinned. In one case, however, the scar resisted contractions for thirteen hours until complete effacement and dilatation had occurred. In the other case the scar resisted contractions for six hours without rupture. A temperature of over 38° C. occurred twelve times during the puerperium, but in most instances it was transient, lasting for only a few days. One prolonged case of sepsis ended fatally.

ZINSSER.

Kitner, O.: Cæsarean Section of the Dead and the Dying Woman (Kaiserschnitt an der toten und sterbenden Frau). *J. akush. i. jensk. boliez.*, St. Petersburg., 1913, xxviii, 539.

By Zentralbl. f. d. ges. Gynäk. u. Geburtsh. s. d. Grenzgeb.

The author reports six cases of Cæsarean section, four on dead, and two on dying, women. Among the former there were two cases of eclampsia, myocarditis cordis with marked pulmonary oedema and hyperæmia, and one marked kyphoscoliosis. The operation was performed within one to ten minutes post mortem. Usually Kitner was forced to operate with unsterile instruments. All of the children were in a more or less severe asphyxia, but were revived.

The two operations upon dying women were for severe eclampsia. The children were born alive. The mothers died within two to four hours after the operation. Kitner is in favor of Cæsarian section in all cases of dead women with viable or living children. It is much more difficult, however, to set the indication on the dying, as the moment of approaching death is determined with difficulty. Cæsarean section should be performed in all cases except those in which the mother is conscious and refuses the operation. Nearly always the child is

saved, and occasionally the mother also. The section on the dead should be performed in all cases under aseptic conditions just as on the living.

GINSBURG.

Veit, J.: The Technique of Cæsarean Section (Zur Technik des Kaiserschnittes). *Zentralbl. f. Gynäk.*, 1913, xxxvii, 713.

By Zentralbl. f. d. ges. Gynäk. u. Geburtsh. s. d. Grenzgeb.

Cæsarean section to-day is a harmless procedure. Schauta advises the use of the transperitoneal instead of the complicated extraperitoneal Cæsarean section. Veit also recommends the classical section for general practice, his reason being that on account of its relative simplicity it can be performed more easily by inexperienced operators. Veit places his patient in the high pelvis position which brings the uterus out of the pelvis. He makes one third of the incision above the umbilicus and two thirds below it. The general peritoneal cavity is walled off with towels, and the uterus incised transversely. An assistant then forces the uterus upward so that the transverse incision lies above the abdominal incision. The placenta and membranes are next removed and the uterus is sutured with silk and a second sero-serous suture of catgut. After the removal of the pads the uterus is allowed to drop into the pelvis. An extreme ante flexion of the uterus is to be avoided, as it may cause rupture. In the manner described the uterus can be emptied without allowing a trace of its contents to enter the peritoneal cavity. The author has operated upon forty patients by this method with good results for the mother in every case.

HOHL.

Pobedinsky, N.: The Results Obtained with Cæsarean Section in Russia During the Last Twenty-Five Years (Die Erfolge des Kaiserschnitts in Russland in den letzten 25 Jahren). *Zentralbl. f. Gynäk.*, 1913, xxxvii, 757.

By Zentralbl. f. d. ges. Gynäk. u. Geburtsh. s. d. Grenzgeb.

Prior to 1885 all but three cases of Cæsarean section performed in Russia ended fatally. Since then 446 operations have been performed including those done for relative indications. Between 1885 and 1890 forty-two operations were performed, principally for contracted pelvis, with a mortality of forty per cent due to bad sepsis and unfavorable conditions. Between 1891 and 1900 there were eighty-four cases, mostly for contracted pelvis, with a mortality of six per cent. The improvement in results was due to better asepsis. Between 1901 and 1912 there are recorded 320 cases, principally for contracted pelvis but also for scar contraction of the vagina, and for tumors. Recently it has also been performed for eclampsia, placenta prævia, stenosis of the cervix and for transverse presentation. The mortality was 7.5 per cent, but only 3.2 per cent if eclampsia and malignant tumors are excluded.

Frequently bad conditions were met, such as examinations by ignorant and dirty midwives, other operative procedures, presence of temperature pre-

ceding the operation, and early rupture of the membranes. Since 1908 the extraperitoneal methods have been employed, but abandoned again, as they proved illusory. Incision through the placenta offers a good prognosis. Simplicity of technique is the keynote and there is but little danger of bladder injury. Dead children were found nineteen times in 320 cases, in twelve of which, however, the indication was absolute. The operation was performed twice on the same patient in thirty-two cases with one death.

Resection of the tube was employed ninety-nine times in twenty-five years for sterilization, the indications being repeated Cæsarean section, tuberculosis and osteomalacia. In the obstetrical clinic at Moscow Cæsarean section on the living was never performed before 1889, because of absence of absolutely contracted pelvis, poor results at other clinics, and poor surroundings. Between 1889 and 1904 contracted pelvis were found in twenty-three per cent of the cases. These were principally treated by prematurely induced labor and craniotomy. The first Cæsarean section was performed in 1895 with good results. Since then thirty-one operations have been performed, chiefly for contracted pelvis. A maternal mortality of nine per cent and a foetal mortality of 0 are recorded. Outside of the clinic there were fourteen Cæsarean sections performed in Moscow between 1886-1900.

WETZEL.

LABOR AND ITS COMPLICATIONS

Paine, A. K.: Some Aspects of Labor Mechanism at the Pelvic Brim. *Boston M. & S. J.*, 1913, clxix, 154. By Surg., Gynec. & Obst.

The author states that he finds from a study of the female pelvis in cadavers and skeletons that the promontory of the sacrum does not project a material distance into the inlet. He believes with Spiegleberg, Dorland, and DeLee that in the majority of vertex presentations engagement in the transverse diameter of the inlet is the rule.

Paine believes that in high forceps operations the axis traction blades may be applied antero-posteriorly to the sides of the head, provided the perineum is well dilated previous to the application. Very little force is necessary to bring the head into the pelvis in any case in which the operation is justifiable, provided the soft parts are properly dilated.

C. H. DAVIS.

Lehle: The Treatment of Frontal Presentation (Die Behandlung der Vorderhauptslagen). *München. med. Wchnschr.*, 1913, lx, 860. By Zentralbl. f. d. ges. Gynäk. u. Geburtsh. s. d. Grenzgeb.

This rare abnormal presentation was found 320 times in 3914 labors of the Munich gynecological clinic. Concerning the etiology of the frontal presentation none of the commonly mentioned causes were frequently met with. The child plays the chief rôle in the origin of the frontal presentation

more often than the mother. Foetuses of small and middle weight were found in the overwhelming majority (84.3 per cent), while large children weighing more than 3500 gm. with a normal-sized or over-sized head were seen in 15.7 per cent.

The prognosis is relatively favorable for the mother. Spontaneous expulsion of the child occurred in 77 per cent of the cases, the remaining 23 per cent necessitating surgical intervention. The forceps were used 65 times (20.2 per cent), version and extraction 4 times (1.2 per cent), version and perforation of the head 5 times (1.6 per cent). The prognosis for the child is not so favorable. In the 323 cases of frontal presentation 57 of the children were more or less asphyxiated and one died. Thirty children died (9.4 per cent), death being directly or indirectly due to the course of labor. Those deaths are included which took place during the first 3 or 4 days after labor, the result of trauma sustained during birth (hæmorrhages of the brain). In the 65 cases which were terminated by the forceps, the delivery of the head was impossible seven times.

If the extraction with forceps in frontal presentation is impossible the author recommends the method of repeated applications of the forceps as taught by Scanzoni in order to improve the position of the head. The operation consists in applying the forceps diagonally, the concavity being applied to the frontal part of the head. The head is then rotated to a transverse position by a simultaneous traction of the forceps downward. The forceps are removed and again applied as in the low transverse presentation (concavity directed against the occiput). The head is rotated to the median position and delivered in the occipital posterior presentation. The results of the operation are very favorable. The technique is not difficult. All seven cases mentioned above would have terminated favorably, if treated in this manner.

In conclusion the following rules are given for the treatment of frontal presentation: 1. Long-continued expectant treatment which results in 77 per cent of spontaneous births. 2. Combined external and internal rotation of the foetus according to Fehling's method with corresponding positions of the parturient woman. 3. If Fehling's method is unsuccessful, delivery of the child in frontal presentation. 4. If these prove ineffectual, Scanzoni's procedure must be performed.

HIMMELHEBER.

De Bovis, R.: Acute Dilatation of the Stomach During Labor and Immediately Thereafter (La dilatation aiguë de l'estomac chez les parturientes et les nouvelles accouchées). *Semaine méd.*, 1913, xxxiii, 169. By Zentralbl. f. d. ges. Gynäk. u. Geburtsh. s. d. Grenzgeb.

Although acute dilatation of the stomach quite often follows surgical operations, it is exceedingly rare during labor and the early puerperium, only ten such cases having been published thus far. These cases the author divides into three groups according to the pathogenesis.

In the first of these groups he places the idiopathic or true obstetrical cases, i. e., those without preceding gastro-intestinal disturbance and without anæsthetic during labor. Prolonged and painful labor, eclampsia, and constitutional injury induced by loss of blood, intoxication, eclampsia, or infection, together with an increase in the ptosis due to rapid delivery and traction on the mesentery may be predisposing factors. In one case of contracted pelvis and breech presentation, the author attributed the dilatation to compression of the duodenum by the head. In other cases the swallowing of air aided the dilatation which was due primarily to accumulation of gas within the bowel.

The second group includes cases following anæsthesia for such operative interference as Cæsarean section. In these it is difficult to state how much the obstetrical element contributes to the purely surgical cause.

In the third of his groups the author considers those cases in which the dilatation is merely an accidental complication of pregnancy as shown in a case of perforated gastric ulcer with intestinal obstruction and in another of Cæsarean section in a cachectic patient suffering from uterine cancer. In another instance the author attributed the dilatation to excessive loss of blood due to placenta prævia. The mortality of the 17 cases published, excluding three patients who died of perforation by gastric ulcer, hæmorrhage, and cancer cachexia, was 3, or 21 per cent. The treatment is the same as that in cases due to surgical interference, i. e., abdominal position, gastric sounding, and lavage.

VASSMER.

Ries-Finley: Uterine Dystocia, Secondary to Mitral Stenosis. *Northwest Med.*, 1913, v, 196.

By Surg., Gynec. & Obst.

The author reports a case and tabulates the following general principles regarding valvular heart disease.

1. Of all the varieties of chronic valvular heart disease mitral stenosis is most commonly accompanied by heart failure during pregnancy.

2. Aortic stenosis without mitral stenosis is rare in women; few cases of pregnancy in women who have aortic without mitral disease come under observation.

3. When symptoms of heart failure have preceded pregnancy, they are made worse by pregnancy.

4. Repeated pregnancies at short intervals cause greater risk of heart failure than do few pregnancies at longer intervals.

C. H. DAVIS.

PUERPERIUM AND ITS COMPLICATIONS

Freeman: Incidence of Malaria in the Puerperium. *Southern M. J.*, 1913, vi, 429.

By Surg., Gynec. & Obst.

The author believes that malaria is a fairly frequent complication in the puerperium. He mentions the following points in establishing the diagnosis:

1. Absence of any demonstrable signs of sepsis.
2. Periodicity, or the return of the fever at a definite time. His experience shows that with the malaria there is a definite return of fever on the third or fourth day.

3. Examination of the blood for plasmodia. Positive findings are absolute, but negative findings are not.

4. Control of the fever and restoration of the patient by quinine.

In the discussion, prophylactic doses of quinine were advised during the puerperium whenever there is a history of malaria.

C. H. DAVIS.

Öhman, K. H.: Ovarian Abscess After Labor (Ett Fall af pyovarium efter partus). *Finska läk.-sällsk. handl.*, Helsingfors, 1913, lv, 447.

By Zentralbl. f. d. ges. Gynäk. u. Geburtsh. s. d. Grenzgeb.

Öhman reports a case of ovarian abscess in a primipara, 31 years old. The pyo-ovarium formed in connection with labor. The patient was successfully operated upon five months after labor. Streptococci were found in the pus. The ovary was the size of a goose egg with one large, and several smaller, abscesses. The tube of the corresponding side and the adnexa of the other side were healthy. Part of the ovarian stroma was still present. Microscopical examination showed that only the outer 0.5 cm. of the abscess wall was intact. In this wall were found connective tissue proliferation, numerous plasma cells and polynuclear leucocytes. The eosinophile cells had penetrated more deeply into the intact tissue layer than the others. The contents of the abscess cavity consisted for the most part of polynuclear leucocytes, eosinophiles, a few lymphocytes and here and there a plasma cell. The bacteria did not take the stain in the sections.

BJÖRKENHEIM.

MISCELLANEOUS

Engelhorn: The Biological Diagnosis of Pregnancy (Zur biologischen Diagnose der Schwangerschaft). *Zentralbl. f. Gynäk.*, 1913, xxxvii, 731.

By Zentralbl. f. d. ges. Gynäk. u. Geburtsh. s. d. Grenzgeb.

Engelhorn reviews Abderhalden's method for the diagnosis of pregnancy and the results so far published that have been obtained by it. He, himself, has tested the dialysis method in 108 cases. In each instance he used the serum of both pregnant and non-pregnant women. The results were as follows: In 60 cases of pregnancy the reaction was positive 49 times from the fourth to the tenth month and negative 11 times during the ninth and tenth months. In 48 non-pregnant women, among whom were women with normal genitalia, with prolapse, cancer, tumors, and lying-in women, the reaction was positive in 31 cases and negative in 17. The author examined also the action of the serum of pregnant and non-pregnant women on coagulated cancerous tissue, fetal liver tissue, and ovaries. The results were contradictory. He does not consider

Abderhalden's dialysis method a specific reaction as a diagnosis cannot be rendered by it. RUHEMANN.

Jellinghaus and Losee: The Sero-Diagnosis of Pregnancy by the Dialyzation Method. *Bull. Lying-In Hosp., N. Y., 1913, ix, 68.*

By Surg., Gynec. & Obst.

Their experiments are based on 563 examinations of different individuals and while not absolutely conclusive, they favor the opinion that it is possible by the dialyzation method to distinguish between healthy pregnant and healthy non-pregnant women.

ROBERT T. GILLMORE.

Abderhalden, E.: The Diagnosis of Pregnancy by Means of the Dialytic and Optical Methods (Die Diagnose der Schwangerschaft mittels des Dialysierverfahrens und der optischen Methode). *Deutsche Gesellsch. f. Gynäk., Halle, 1913, May.*

By Zentralbl. f. d. ges. Gynäk. u. Geburtsh. s. d. Grenzgeb.

Abderhalden gives a review of the principles of ferment reaction in the body and explains the dialyzation and optical methods. He holds that the methods are theoretically correct and the bad results reported are unquestionably due to poor technique.

The sources of the error are as follows: 1. The blood used is hemolytic or is not well centrifugalized, containing cells which digest in the dialyzing test. 2. The thimbles used are not well tested and constant. 3. The organ has not been thoroughly freed from coagulable bodies which react with ninhydrin. If the serum alone and the organs alone contain each less than enough amino acids to give a positive reaction when placed together, the addition may be enough to give a reaction though no digestion has taken place. This may occur in conditions like carcinomata, in salpingitis and hæmatomata where proteid products are absorbed in the blood. Only a violet or bluish color is positive.

Mayer, A.: Abderhalden's Pregnancy Reaction (Die Abderhaldensche Schwangerschaftsreaktion). *Deutsche Gesellsch. f. Gynäk., Halle, 1913, May.*

By Zentralbl. f. d. ges. Gynäk. u. Geburtsh. s. d. Grenzgeb.

Mayer considers Abderhalden's pregnancy reaction a valuable aid to diagnosis. By its use it is possible to determine whether the conception took place just before the first missed period or just after the last one. The reaction is positive in cases of recent extrauterine pregnancy, but negative in old cases in which hæmatoceles have formed and functioning placental tissue is no longer present. The chief value of Abderhalden's method consists not in the diagnosis of pregnancy, but in the study of the pathology of the internal secretions. For the latter study Mayer used the male and female germinating glands.

The serological behavior towards the female germinating glands with their great influence on the entire organism is of particular interest. We know of many diseases in which we suspect a dysfunction

of the ovary. Mayer included in his investigations cases of climacteric neurasthænia, hysteria, metro-menorrhagia, dysmenorrhœa, amenorrhœa, myoma, etc., in which we often find macroscopically changed ovaries. The practical value of these investigations is shown by a positive Abderhalden reaction towards the ovary in a case of metro-menorrhagia and a case of amenorrhœa. This means that in these instances there was a dysfunction of the ovaries and the hæmorrhage was oöphorogenous. A curettement, which is the usual treatment for these cases, would hardly have been successful, as it attacks the endometrium and not the diseased ovary.

Pregnancy also shows interesting conditions. Diseases such as osteomalacia, vesicular mole, emesis, and, perhaps, eclampsia, are believed to be due to disturbances in the ovarian function, particularly of the corpora lutei. It is possible that the serum of diseased pregnant women may react differently toward the ovary or corpus luteum from that of pregnant women.

Schäfer, P.: Abderhalden's Ferment Reaction (Fermentreaktion nach Abderhalden). *Deutsche Gesellsch. f. Gynäk., Halle, 1913, May.*

By Zentralbl. f. d. ges. Gynäk. u. Geburtsh. s. d. Grenzgeb.

Schäfer examined one hundred and twenty-three cases with Abderhalden's dialysis method sixty-five of these also with the optical method; sixty-two were pregnant and sixty-one were not. He found two incorrect diagnoses in the pregnant. Hæmatoceles gave varying results. In the non-pregnant he had eleven incorrect diagnoses, the greater number of which were found in cases of carcinomata and myomata. In twenty-three cases of tumors he had nine failures, and in thirty-eight cases of women with normal genitalia or senile atrophic genitalia he had two failures. With the optical method correct diagnosis was missed twice, a positive reaction having been obtained in a case of myoma and a negative reaction in a case of cornual pregnancy at the second month. Two cases of pregnancy and four cases of cervical cancer split off placental tissue as well as peptone-free cancer tissue.

Petri: The Specificity of the Placenta-Splitting Ferments of Pregnancy Serum (Über die Spezifität der gegen Placenta gerichteten Fermente des Schwangerschaftsserums). *Zentralbl. f. Gynäk., 1913, xxxvii, 731.*

By Zentralbl. f. d. ges. Gynäk. u. Geburtsh. s. d. Grenzgeb.

The history and development of Abderhalden's reaction is given in detail. To test the specificity of this reaction Petri attempted to determine whether the serum of pregnant women is capable of splitting albumin other than placental albumin, and whether placental albumin can be split by the serum of non-pregnant women. In both of his experiments he obtained negative results. The placenta was split only by the sera of two very anæmic myoma patients, the serum of a patient with a tubo-ovarian cyst, and that of a patient with

recurrent cancer of the breast. On the theory that, as a protoplasm foreign to the blood, the spirochetes that are contained in the blood of luetic patients could cause the formation of ferments, the author examined the sera of luetics. Only cases that had received treatment gave positive reactions. In explanation of this remarkable fact Petri states that spirochetes which have not been injured are so powerfully viable that the organism is not able to form ferments against them until they have been weakened by mercury or salvarsan. RUHEMANN.

Decio: The Fat and Cholesterin Content of the Blood in Pregnancy and the Puerperium under Normal and Pathological Conditions

(Sul contenuto in grasso e colesterina del sangue delle gravide e delle puerpere in condizioni normali e patologiche). *Ann. di ostetr. e ginec.*, 1913, xxxv, 281. By Zentralbl. f. d. ges. Gynäk. u. Geburtsh. s. d. Grenzgeb.

The author examined the serum of 53 pregnant, puerperal, and normal women to determine the fat and cholesterin content of the blood in these conditions. Blood was obtained at the same hour each day, 4 hours after a meal, so as to exclude digestion lipæmia. He found a slight increase during the first few months of pregnancy, gradually increasing until the end. The same findings are present during labor and early puerperium as during the last months of pregnancy. No difference existed between primipara and multipara.

The cause of the accumulation of fatty substances the author attributes to a decrease in the lipolytic ferment, to a general sluggishness of the processes of oxidation in the pregnant organism and to an increased assimilation of food. The increased activity of the organs of internal secretion, especially of the adrenal and corpus luteum, may account for the production of lecithin and cholesterol. In eclampsia the fatty substances are particularly increased. The author considers the cholesteræmia a protection against the toxins of pregnancy. For figures and the method of procedure the reader is referred to the original.

SEMON.

Fraenkel: Internal Secretion and Pregnancy (Innere Secretion und Schwangerschaft). *Deutsche Gesellsch. f. Gynäk.*, Halle, 1913, May.

By Zentralbl. f. d. ges. Gynäk. u. Geburtsh. s. d. Grenzgeb.

1. The antibodies which Fraenkel used in the treatment of osteomalacia are biological, not biochemical. They are the secretions of the other blood-forming glands which have become dormant in the serum of those castrated. 2. Fraenkel did not find interstitial glands in the uterus walls in his far-reaching comparative examinations and they were not confirmed by anyone in the transactions of the Congress. However, the reproductions of specimens made by Seitz and Wallart convinced him that it may occur. Their inconsistency, however, excludes a specific function. 3. The claim that ovulation regularly occurs during the intermenstruum has been confirmed by Villemin, John

Miller, Robert Meyer, Seitz and Schroeder. Seitz justly criticises Fraenkel for making macroscopical examinations in living persons with healthy internal genitalia. However, this is better than all the other methods which make use of extirpated diseased genitalia, since the exact determination of the age of the corpus luteum cannot be made microscopically. 4. The corpus luteum law has not been doubted by anyone. Seitz and Landsberg confirm it, using entirely different methods.

Josephson, C. D.: The Proof of the Presence of Spermatozoa in the Cervical Canal in Two Cases of Rape Eighteen Hours after the Perpetration of the Crime (Spermatozoer pavisade i cervix uteri i två fall av våldtäkt 18 timmar efter våldet). *Allm. sven. Läkartidn.*, Stockholm, 1913, x, 245.

By Zentralbl. f. d. ges. Gynäk. u. Geburtsh. s. d. Grenzgeb.

The author describes two cases in which he was able to demonstrate the presence of spermatozoa in the cervical discharge eighteen hours after the perpetration of rape. None were found in the vagina. In one case the discharge was removed with a cotton swab on a metal applicator and spread on a glass slide; in the other it was obtained with a Braun's syringe. Several applicators saturated with wood vinegar were then introduced into the uterine cavity to prevent conception if possible.

The author refers to the studies of Blumm and Runge in regard to the length of time that spermatozoa may survive in the vagina and uterus, and discusses the methods of examining for them in these organs. BJÖRKENHEIM.

Warnekros: Placental Bacteræmia (Placentare Bacteriæmie). *Deutsche Gesellsch. f. Gynäk.*, Halle, 1913, May.

By Zentralbl. f. d. ges. Gynäk. u. Geburtsh. s. d. Grenzgeb.

The usual positive findings in the blood during febrile abortion have led the author to bacteriologically examine the blood of patients during pyrexia in the course of labor. In each case the examinations were systematically conducted as follows: 1. Removal of secretions from the uterine cavity before delivery. 2. Blood was obtained from the veins before and after delivery. 3. Bacterioscopical staining of microscopic sections from the placenta and its membrane.

Of the thirty cases examined the temperatures were always higher than 38.5° C. The blood tests, always made before delivery if high temperatures or rigors occurred, were positive in twenty-one; i.e., more or less numerous colonies of bacteria were demonstrated in the large glucose agar tubes. Infections were mostly mixed. The examination of the blood which was removed after delivery remained sterile with one exception. This patient died three days post-partum from sepsis. Another patient succumbed to tuberculosis which rapidly progressed during the puerperium. In all the other cases the fever subsided rapidly and the patients were discharged cured. Both blood examinations remained

sterile in nine cases, bacteria not being found either before or after delivery. None of these women died.

The fever is caused by the bacteria or by an absorption of their toxins. These sporadic findings in the blood which are positive only during labor find an anatomical cause in the placenta. The placenta were delivered under aseptic precautions; portions were cut out in different places, embedded and stained for bacteria. The examination showed that the germs were found in the subamniotic layer of the chorion in all protracted labors and it did not matter whether bacteria were demonstrated in the blood or not. In those cases in which the blood findings were positive the bacteria traveled from the amniotic cavity through the entire layers of the membranes and the decidua basilaris which was thickly permeated with bacteria, especially at its lower placental pole. An invasion from the decidua into the intervillous spaces could be observed.

Numerous bacteria were also found within the placenta between the villi. The behavior of the bacteria in these temporary placental bacteræmias, towards the uterine wall is of special interest. A positive proof of this is naturally rendered with difficulty, as cases which recover could not be used for this investigation. However, such a uterus was obtained for an examination. It was from a patient who entered the hospital with a very high fever. Streptococci grew in the blood which was obtained before delivery. Labor was terminated by a perforation of the dead child. The patient died from a severe anæsthesia asphyxia after the delivery of the child. The placenta was still in the uterus. The organ with the placenta was removed in toto, hardened, and cut in sections. The bacterioscopic examination showed an infection of the placenta. The bacteria had permeated the amniotic membranes and were seen in the intervillous spaces. They were further seen in the canals of the afferent veins. However, an infection of the uterine walls had nowhere taken place, the uterine musculature being absolutely free of any bacteria, so that a purely placental infection existed. This case must be considered as one of those in which the patients have fever during labor, have bacteræmia, are immediately delivered and then rapidly recover.

Warnekros concludes that if bacteria reach the uterine cavity after a premature rupture of the sac, a bacterial decomposition of the amniotic fluid ensues. If the blood remains free from bacteria, the clinical picture is less stormy and pronounced rigors are absent. The rise in temperature is a result of an absorption of toxins from pathogenical micro-organisms, these toxins being formed in the uterus. This primary toxæmia is only a transitional stage sooner or later followed by an invasion of the bacteria into the blood stream. Hence all forms of severe fever during labor are acute placental bacteræmias. The indication for treatment resulting from these investigations is that where women have a rise in temperature during labor, they must be delivered immediately.

Bordé: The Location of the Placenta (Sulla sede della Placenta). *Ann. di ostetr. e ginec.*, 1913, xxxv, 248.

By Zentralbl. f. d. ges. Gynäk. u. Geburtsh. s. d. Grenzgeb.

Bordé, on 100 after-births in which the exit of the child through the membrane could be seen distinctly, measured the least and the greatest distance of the edge of the placenta from this opening so as to determine the seat of the placenta. In 65 cases he found the edge of the placenta not more than 8 cm. from the uterine os; 11 of these were primipara. In 25 cases the placenta was only 4 cm. or less from the outlet of the uterus; 38 times he found it between 4 cm. and 8 cm. Bordé considers that the placenta usually is located in the lower part of the uterus.

WIEMER.

Costa, R.: The Placenta of Giant Infants (Osservazioni sulle placente dei feti macrosomi). *Ann. di ostetr. e ginec.*, 1913, xxxv, 253.

By Zentralbl. f. d. ges. Gynäk. u. Geburtsh. s. d. Grenzgeb.

On the basis of the findings of the microscopical examinations made in twenty-eight cases of giant fetuses the author divides the placenta into two groups. Those of the first group are characterized by a finer structure which is essentially the same as that of children of normal growth. Those of the second group have a decidedly greater number of chorionic villi, which are mostly small and densely crowded together, a marked development of the capillary vessels within the villi, and a striking congestion of the intervillous spaces. Both groups show a pronounced deposit of fat, with the smaller fat droplets in the periphery, and the larger ones in the center, of the villi. On account of these findings the giant growth is thought to be due to an increase in the foetal metabolism.

COLOMBINO.

Asch: Intra-Uterine Sucking (Über intra-uterine Ernährung). *Monatschr. f. Geburtsh. u. Gynäk.*, 1913, xxvii, 701.

By Zentralbl. f. d. ges. Gynäk. u. Geburtsh. s. d. Grenzgeb.

Asch observed in a corresponding location on the skin of both forearms of an overmatured child a defect which resembled a burn. When the arms were brought close to the child's mouth it immediately began to suck on the injured portion. Asch later observed another child who had distinct sucking marks on the forearm and the backs of the hands. He concludes that children may practice nursing during intra-uterine life and that to this circumstance the described changes in the skin are due.

ZINSSER.

Zangemeister: A Young Human Embryo (Junges menschliches Ei). *Deutsche Gesellsch. f. Gynäk.*, Halle, 1913, May.

By Zentralbl. f. d. ges. Gynäk. u. Geburtsh. s. d. Grenzgeb.

The author demonstrated sections of a young human embryo. It was characterized not so much by its youth as by the fact that it filled out an embryological link. The uterus was extirpated in this

case eleven days after a period was missed. The embryo was about twenty-one days old according to embryological data. The uterus was carefully opened and immediately preserved. A number of pictures were made. In the first picture was seen the anterior surface of the uterus with the groove opposite the egg capsule; in the second was seen the posterior surface with the flat ovum deeply embedded in the thickened mucous membrane. The ovum itself measured only 11 mm. In the third and fourth pictures the ovum was opened; one could see the broad villous space, the cavity and the embryo. The first microscopical picture showed the numerous dilated glandular spaces; around them the compact layer and then the villous zone with the intervillous spaces. The villi were without vessels and the intervillous spaces were filled with cloudy albumen-like material. It was especially noticeable that although it was not a very young ovum, nevertheless there was no blood in the intervillous spaces. It could, therefore, be concluded that blood is not normally found in the intervillous spaces so early in the human, and that nutrition must take place from the substance mentioned.

The extensive development of the mesodermal part of the villi was remarkable when the smallness of the embryo was considered. The embryo was connected to the chorion by means of the abdominal pedicle. The amniotic cavity was a flat space surrounding the dorsal side of the embryo. The next picture showed the same parts but much enlarged and showed the still open medullary groove. From the bowel anlage a small protrusion was given off, the allantois. In the abdominal pedicle numerous vessels were observed. The next section passed through the middle of the body. Here again could be seen the small amniotic cavity. The yolk sac was represented by a thin-walled, lax, much folded sac. Above the cord was found the closed spinal canal; on both sides of it could be seen segmented somites; to their side the somatic plates with the cœlomic fissure which was continued into the exocoelom.

In addition to the demonstration the author discussed the age of the embryo. A large number of young human embryos are now on hand. If these dated from a definite phase of the ovulation and menstruation cycle, i. e., if fecundation occurred only in a limited period of the ovulation cycle, then the different ova insofar as the relation to the last menstrual period is concerned, would make a regular curve, presuming a similar rate of growth for all. The author investigated the different reported ova according to size and age after the last menstrual period. He found that the facts so ascertained regarding them are spread out over a considerable space of time and that it is utterly impossible to plot a curve. From this we can conclude that the age of the ovum may show considerable variation even though the interval after the last menstruation is the same. If one now considers the age according to embryological development it can be seen that

fecundation may occur at any time between two periods, but that the time when fecundation is most likely to occur is about a week before the first period missed. If the age is correct when judged according to embryological development, then the different ova ought to render a definite curve. That is indeed the case. The curve produced by the length of the embryo and of ova is almost identical with the above curve. From these curves the age of the embryo when judged according to development is approximately correct.

In regard to the absolute age of the ovum nothing definite can be stated in the human as the assumed latent period (in which no growth can be demonstrated) may be considerably shorter than supposed. From a study of the curves the author would rather believe that to be the case. If that is a fact, then all the known ova are considerably younger than they are supposed to be. This, however, may be ascertained later by further studies on animals, which can be accurately controlled.

Wagner, G. A.: Contributions to the Question as to the Origin of the Amniotic Fluid, with Pathological-Anatomical, Experimental, and Clinical Examinations of the Functions of the Foetal Kidneys (Beiträge zur Frage der Herkunft des Fruchtwasser mit pathologisch-anatomischen, experimentellen und klinischen Untersuchungen über die Funktion der fötalen Nieren). Leipzig and Vienna: Deuticke, 1913.

By Zentralbl. f. d. ges. Gynäk. u. Geburtsh. s. d. Grenzgeb.

To date, the question as to whether normally the fetus secretes urine in utero has not been answered. The author has attempted to solve the problem by pathological-anatomical, experimental, and clinical investigations. He concludes that the foetal kidney does not functionate under normal conditions and therefore does not take part in the formation of the amniotic fluid.

The report contains also a detailed account of foetal malformations such as closure of the urethra, dilatation of the urinary bladder, and hypo- and hyperplasia of the kidney. It gives also a description of the experiments undertaken to determine the function of the foetal kidneys, and the results of the examinations of the urine of the new-born. An extensive bibliography is appended.

ZANGEMEISTER.

Bublitschenko, L. I.: Blennorrhœa of the New-Born and Its Prevention (Blennorrhœa neonatorum und deren Verhütung). *Med. Rundschau*, 1913, xl, 540.

By Zentralbl. f. d. ges. Gynäk. u. Geburtsh. s. d. Grenzgeb.

Examination was made of smears and cultures of the secretion from the eyes of new-born children affected with gonorrhœal and non-gonorrhœal diseases. The author is of the opinion that the conjunctiva of the new-born, especially in the first days of life, is comparatively more sensitive to all kinds of inflammatory diseases than the conjunctiva of adults. The causative factor of the severe eye in-

flamations is usually the gonococcus. Also at times this coccus may produce merely a slight catarrh. It is possible that more than one half of the blennorrhœas are produced by streptococci, pneumococci, etc. There are also blennorrhœas the biological causative factor of which cannot be determined. Intra-uterine blennorrhœas usually result from a dissemination of the infecting agents through high lacerations of the amniotic membranes.

The author gives statistics of the prophylactic treatment of gonorrhœa with different remedies and in conclusion reports his own experience. He prefers weak, non-irritating solutions such as 5 to 10 per cent solutions of protargol as recommended by Ahlfeld, and especially a solution of sublimate 1:4000. He states that as the result of the regular disinfection of the hands of the attendants and the bodies of the parturient women with a 1:2000 solution of sublimate, and of the eyes of the new-born with a 1:6000 solution of sublimate, the number of conjunctivitis was reduced from 0.3 per cent in 1904-1907 to 0.17 per cent in 1909-1911.

KRINSKI.

Nádory, B.: Simple Surgical Treatment of the Umbilical Stump (Einfache chirurgische Versorgung des Nabelschnurrestes). *Zentralbl. f. Gynäk.*, 1913, xxxvii, 765.

By *Zentralbl. f. d. ges. Gynäk. u. Geburtsh. s. d. Grenzgeb.*

The method recommended by the author complies with the three requirements of Ahlfeld; i. e., that there be positive prevention of an infection, protection against secondary hæmorrhages, and no necessity for after-treatment. As soon as the pulsation of the umbilical cord ceases, the cord is tied tightly with a heavy silk ligature at the line of demarcation between the skin and Wharton's jelly. The cord is then cut short. The stump and umbilical ring are painted with tincture of iodine. The child can be bathed daily if an application of the tincture of iodoine is made after the bath. The umbilical stump will fall off on the second or third day. The umbilical funnel heals rapidly. J. VOIGT.

Freudenthal: A New Procedure for the Enlargement of the Generally Contracted Pelvis (Ein (neuer) Kunstgriff zur (unblutigen) Erweiterung des grad-verengten Beckens). *Berl. klin. Wchnschr.*, 1913, I, 688.

By *Zentralbl. f. d. ges. Gynäk. u. Geburtsh. s. d. Grenzgeb.*

The author reports his method of gaining more room in contracted pelvis. It is as follows: After rupture of the membranes, the entrance of the head is aided as follows: A roll is laid under patient's back, each knee is grasped by an assistant, (leg pointing outward) and during each pain it is brought closely to the median line of the abdomen, even pressing against it. Labor is rapid and uneventful.

The explanation is as follows: On account of the passive fixation of the femur, the gluteal muscles inserted on the trochanters are contracted in the effort to stretch out the legs, nolens volens, and exert

outward traction on the ilia. Stretching of the sacro-iliac ligaments results, the promontory recedes and the antero-posterior diameter is increased.

WETZEL.

Von Hoytema, D. G.: The Use of Pituitrin in Obstetrics (Pituitrine in de verloskundige praktijk). *Nederl. Mandschr. v. verlosk. en Vrouwenz.*, 1913, ii, 296.

By *Zentralbl. f. d. ges. Gynäk. u. Geburtsh. s. d. Grenzgeb.*

From his own practice and that of his colleagues the author has collected 88 obstetrical cases in which pituitrin was employed. In 11 of these it was used for post-partum hæmorrhage; in the remaining 77, as an ecboic. In four cases no result was obtained, and in three they were doubtful. In 10 cases there was a moderate, and in 56 cases, a definite, increase in the contractions. In 7 instances it caused powerful contractions. Of the 77 children delivered, 10 were slightly asphyxiated and 7 were dead. Of the latter, 3 were dead before the beginning of labor.

STRATZ.

Rowland: Pituitary Extract in Obstetrics. *Maryland M. J.*, 1913, lvi, 161. By *Surg., Gynec. & Obst.*

In this article the author illustrates the effect of pituitary extract in the induction of labor, the treatment of abortion, and its effect on cases in first and second stages of labor. Four case reports illustrate the induction of labor and treatment of abortion.

Concerning the use of pituitrin in the first and second stages of labor, the author cites twenty-one cases in which the drug was used. In these cases the external os was for the most part slightly dilated and the indication for the use of the drug was ineffectual pains.

In this series Rowland gives four tables of pains, pulse, and blood-pressure to show the relationship of one to the other. In one or two cases the pituitary extract seemed to have no effect, but in the majority of cases pains were increased and labor hastened. In only two of the cases was the foetus asphyxiated or in any way harmed; one was a forceps delivery and the other was also a forceps delivery in an eclamptic after a convulsion, in which instance the child was born dead.

The author states that he got satisfactory results in all cases where there was some dilatation of the cervix or where the head was engaged. In two cases pituitrin was successful in a single dose after an attempt at forceps delivery had failed. Also whenever the head is on the perineum the delivery is always prompt.

Conclusions. 1. Pituitrin is efficient to finish abortion and to induce labor in conjunction with other means. 2. It usually causes advancement of the head with the cervix half dilated. 3. It is most successfully used in the last half of the second stage of labor to save delivery by forceps. 4. It probably causes no danger to the child. 5. It should not be used in toxic conditions with high blood-pressure.

EUGENE CARY.

Heaney, N. S.: A Contribution to the Study of Pituitrin. *Surg., Gynec. & Obst.*, 1913, xvii, 103.
By Surg., Gynec. & Obst.

This article is the result of a clinical and laboratory investigation into the physiological effects of pituitrin. It is divided into two parts, the first taking up the effects of pituitrin upon the normal and elevated blood pressures of human beings, and the remaining part, the effects of pituitrin upon the lactating mammary glands.

Heaney finds that the effects of pituitrin upon the circulation are directly dependent upon the route of administration. When given intravenously it produces an immediate and profound disturbance, a marked increase in blood-pressure of from 20 to 60 mm., and a lowering of the pulse of from 10 to 30 beats per minute, this being accompanied by marked systematic effects, pallor, great anxiety and symptoms resembling collapse. The disturbance is of brief duration, but is severe during the 3 to 4 minutes that it lasts.

Given by intramuscular injection, pituitrin influences the circulation only occasionally and then but slightly. The subcutaneous administration has no pressure effects.

Because of the possibility that an unrecognizable circulatory disturbance may contra-indicate a sudden rise of blood pressure, Heaney advises giving pituitrin intravenously only in grave emergencies, such as severe post-partum hæmorrhage. The subcutaneous method should be the routine procedure, care being taken to avoid puncturing a blood-vessel and introducing this powerful substance into the blood-stream.

In his inquiry into the asserted galactogogic action of pituitrin upon human beings and animals, Heaney was unable to demonstrate clinically that the extract has any effect. He thought that the ejection of milk observed by the original experimenters, which occurred immediately upon the intravenous injection of the hypophysis, might be another expression of the already well-known effects of this substance on the smooth muscle fibres of the body. In these instances it showed its action on the breast muscle bundles, which by their contraction produced a squeezing-out of the milk contained in the breast. Heaney repeated his animal experiments upon human beings, using an instrument to measure the contraction of the breast instead of a cannula inserted into the nipple. In every observation he obtained definite evidence that the breast contracted measurably when the patient received pituitrin intravenously. The knowledge that the breast contracts as a result of this medication, together with the negative clinical results obtained when he tried to increase the milk supply in mothers with failing lactation, leads him to conclude that the

results of the earlier workers in this field were wrongly interpreted; that the stimulus which extracts of the hypophysis seems to give to the milk-flow is really an assertion of the effect that this substance has on all smooth-muscle fibers.

Vortisch-van Vloten: Statistics of a Chinese Policlinic (Statistik einer chinesischen Poliklinik). *Arch. f. Schiffs- u. Tropen-Hyg.*, 1913, xvii, 253.
By Zentralbl. f. d. ges. Gynäk. u. Geburtsh. s. d. Grenzgeb.

The author was consulted 16,000 times by 5,500 Chinese during 1909-1912 when he conducted the hospital Yin Asi in the central part of the province of Canton. Over 3,600 case histories are available. Here only the obstetric and gynecological material is discussed. Four cases of birth anomalies occurred, three of puerperal fever, 14 of menstrual anomalies, 2 of disturbances during pregnancy, 8 of mammary abscesses and tumors, 4 cases of vaginal and uterine catarrh, 2 of vaginal prolapse, and one of ovarian tumor.

The following operations were performed: 2 colporrhaphies, 1 bladder-stone, 1 extirpation of a cancerous vulva. The female residents of that district avoid the "devil's doctor;" a European midwife has never been called to a confinement among them. In another district three to four days distant however she is called quite commonly. Female children are of little consequence in China; they are frequently killed after birth, or if later they prove weaklings, are starved. The care of the umbilical stump is bad; the cord is not dressed, even after the stump falls off. If suppuration sets in chewed leaves are applied; if hæmorrhage occurs, tobacco or earth are put on so that tetanus commonly results. In spite of continuous nursing for two to three years the infant mortality is high, as the children are given everything else in addition.

In cases of pathological labors the author was always called too late. The Chinese women cannot believe that European physicians have learned the obstetrical art. Labors are usually easy; the hips are well developed under the loose mode of dress. Mid-wives are rare; usually mothers-in-law or neighbors render the necessary aids without any asepsis. If the labor is prolonged internal and external massage is resorted to. The after-birth is removed by traction on the cord or by mammal extraction. Labor and puerperium are frequently surrounded by superstition and idolatry.

Among the Europeans there were many menorrhagias and abortions during the first to the third month, probably induced by a latent malaria. Labors in Europeans were usually normal.

The author presents literature in regard to Chinese physicians and their methods of treatment.

VON MILTNER.

GENITO-URINARY SURGERY

KIDNEY AND URETER

De Berne Lagarde and De Beaufond: The Suprarenal Capsules in Cancer of the Kidney (Les capsules surrénales dans le cancer du rein). *Arch. urol. clin. de Necker*, 1913, i, 72.

By Journal de Chirurgie.

Taking up in detail a discussion which was started before the French association for the study of cancer, the authors state that nothing authorizes systematic ablation of the suprarenal capsule in the course of nephrectomy for cancer such as was once recommended by Grégoire.

After a detailed anatomical study of the blood vessels and the lymphatics of the suprarenal, they point out the theoretical dangers of unilateral suprarenalectomy as long as our means for investigating the functional value of these glands in a specific case, and especially the independent value of each one of them, are inadequate. In the anatomopathological chapter they show how rare and often vague are the observations that are published concerning the condition of the suprarenals in the course of cancer of the kidney. By means of a letter written to them personally they prove that Israel did not recommend ablation of the suprarenal in the course of nephrectomy for cancer as he is quoted as having done. They then describe seven hitherto unpublished studies of the suprarenals in cases of cancer of the kidney. Three of these belonged to Legueu and four were mine. Their conclusions are as follows: Of the thirty-seven observations in which mention was made of the suprarenal capsules, no information as to their condition was given in four cases; in eighteen cases the suprarenals were intact, and in fifteen cases they were neoplastic. In eleven of the fifteen cases in which the suprarenals had been invaded there were accompanying metastases in the lungs, the liver, the bones, and the nervous system, and in two of these the suprarenal metastasis was located on the side opposite to the cancer of the kidney. Therefore the disease of the suprarenal may be considered a regular metastasis, a sign of generalization. The systematic ablation of the suprarenal in the course of a nephrectomy for neoplasm is not recommended.

MAURICE CHEVASSU.

Krotoszyner: On the Differential Diagnosis of Appendicitis and Nephrolithiasis. *Cal. St. J. Med.*, 1913, xi, 287. By Surg., Gynec. & Obst.

The author reported a case of an apparent right-sided nephrolithiasis, which proved to be an appendicitis with several fecal concretions.

The diagnosis was made from pain on micturition,

agonizing in character. The urine was cloudy with abundant pus microscopically; meatoscopy showed no urine from the right side, while the right ureteral catheter met an obstruction 15 cm. from the vesical outlet. Chromocystoscopy showed no color from that side within an hour. Radiography showed apparently normal kidney shadows on both sides, with two small well-defined shadows on the right side of the spinal column at the site of the ureteral impediment and apparently in the course of the ureter as ascertained by a shadow-casting ureteral catheter.

On operation the right ureter was found embedded in dense adhesions, and in the attempt to free them the peritoneum was opened and a long and tortuous appendix was found as a part of the adhesions upward and downward to a point near the insertion of the bladder.

Since the operation, no urine can be obtained from the right side and the obstruction is still present at the same site, but as the patient suffers no discomfort she refuses further interference.

LOUIS GROSS.

Ghoreyeb: A Study of the Mechanical Obstruction to the Circulation of the Kidney Produced by Experimental Acute Toxic Nephropathy. *J. Exp. Med.*, 1913, xviii, 29.

By Surg., Gynec. & Obst.

In a study of the influence of disease on the circulation of various organs, as shown by the perfusion method, Ghoreyeb came to the following conclusions as regards the kidney: Blood serum is the most satisfactory fluid available. There is some impediment to the circulation of serum through kidneys in which nephropathy has been produced by uranium nitrate, potassium chromate, potassium arsenate, cantharidin, and diphtheria toxin. The histological changes in the cells of these kidneys — swelling of the epithelium and changes in the glomeruli — are such as would produce obstruction. The circulatory obstruction is greatest in those kidneys in which the above changes are most marked. In the kidneys in which the drug has caused destruction of the cells the impediment is less marked than in those in which the cells are swollen but otherwise intact.

The impediment to the flow of perfusing serum is in direct relation to the anatomical obstructive lesion, and tends toward normal with the cessation or healing of the process. Bacteria, though present in large numbers, impede but little the flow through the kidney. Rabbits may have spontaneous nephropathy and show no casts or albumen. A certain amount of obstruction is noted in these cases.

JAMES F. CHURCHILL.

Payne and Macnider: An Experimental Study of Unilateral Hæmaturia of the So-Called Essential Type. *Surg., Gynec. & Obst.*, 1913, xvi, 93.
By Surg., Gynec. & Obst.

Payne and Macnider review the literature on this subject and report five cases of unilateral hæmaturia of the so-called idiopathic type, which were relieved of all symptoms by nephrotomy. The authors are inclined to believe that in the majority of these cases the condition is one of chronic inflammation of one type or another. A series of experiments was conducted for the purpose of excluding certain acutely developing vascular changes as being the principal cause for the occurrence of blood in the urine.

The experiments came in three groups: (1) Those in which it was attempted to induce a hæmaturia by interference with the vaso-constrictor nervous mechanism of the kidney. (2) Those in which a hæmaturia was attempted by the introduction of a nephrotoxic substance into the renal artery which had a special affinity for the vascular element of the kidney. (3) Those in which the blood supply to the kidney was interfered with by occluding the renal artery by the use of a clamp. These experiments would, therefore, apparently contradict Klemperer's theory that angioneurotic œdema, and also Albarran's idea that a slight lesion of nephritis, is a sufficient cause of the unilateral hæmaturia. Finally it seems most probable, since acute nephritis can be eliminated, that the clinical condition is due to a chronic nephritis; one in which there is a rupture of a glomerular vessel and the bleeding kept up by the high local pressure so constantly found in chronic nephritis.

Newman, D.: Renal Varix and Hyperæmia as Causes of Symptomless Renal Hæmaturia. *Brit. J. Surg.*, 1913, i, 4. By Surg., Gynec. & Obst.

The author states that there is always a cause for symptomless renal hæmaturia. This article deals with two of the more obscure causes, namely, renal varix and renal hyperæmia. The only symptom of both these conditions is a painless hæmaturia. The fact that the blood comes from the kidney is established by means of the cystoscope. As a rule, rest has little effect upon the hæmorrhage from renal varix, but it may temporarily stop the hæmorrhage from renal hyperæmia.

If in the treatment of these cases the bleeding does not respond to rest, the kidney should be exposed and its position examined. Any pressure or distortion of the renal vein should be removed and the kidney anchored in such a position that a twist or pressure cannot recur. If the kidney position seems normal, the kidney should be split, and the papillæ carefully examined for varices. Any varices found should be removed either by cauterization, or by cutting away the papillæ.

Sometimes it is impossible by operation to find the source of the hæmorrhage and even after the kidney is split, the bleeding may continue. If the hæmor-

rhage is severe and the patient is getting weak, the kidney should be removed.

The technique recommended for splitting the kidney is to pass a silver wire, threaded upon a liver needle, into the pelvis of the kidney and out again. The wire should then be drawn through the kidney substance with a sawing motion. V. LESPINASSE.

Israel, W.: Pyelotomy (Zur Pyelotomie). *Ztschr. f. Urol.*, 1913, vii, 524.
By Zentralbl. f. d. ges. Chir. u. i. Grenzgeb.

In Israel's clinic pyelotomy is given the preference over nephrotomy. However, in forty-two consecutive operations for renal calculus nephrotomy has been performed eighteen times during the past three and a quarter years. The author emphasizes the importance of a good X-ray picture. In pyelotomy drainage was employed only when there was much sand or gravel present and then only with a view to later pelvic irrigation. The pelvic wound healed without the formation of a fistula even when it was not possible to suture it exactly. The peripelvic fat was carefully sutured in all cases. SCHULZE.

Corbett, F. J.: A Form of Experimental Nephritis. *Urol. & Cutan. Rev.*, 1913, xvii, 358.
By Surg., Gynec. & Obst.

The author divides his studies into three groups. In the first group he describes the condition of kidneys after the ureter has been tied for twenty-four hours, six days, and twenty-six days. The twenty-four hour kidney he found to be larger and heavier than normal. It presented a mottled appearance upon section. The convoluted tubules might have a dilated lumen, a compressed epithelium often showing obliteration, and degeneration or necrosis of the epithelial cells. The blood vessels were dilated. The six-day kidney was pale, œdematous, and increased in size. There was a deformity of the tubules and round-celled infiltration. The twenty-six day kidney was white in color and presented a picture of extreme hydronephrosis. The tubules were dilated, the epithelium deformed, and fatty changes were noted in the epithelium. The epithelial cells were pigmented.

In the second group Corbett assembles those kidneys in which there had occurred marked fatty changes accompanied by a deformity of the tubules, but with very little cell necrosis or degeneration and comparatively little interstitial change. In these kidneys he found that fatty degeneration began in the twenty-four hour kidneys and extended through the whole series in a large per cent of the cases.

In the third group the author cites only one case. This was as follows: The cross section showed a great deal of œdema and in one place an infarct. Cultures from the urine were sterile. In the areas remote from the infarct the microscopical picture showed so much œdema that some of the tubules seem to be actually compressed. The cells of these tubules appeared swollen and abnormal. These pictures suggested potential atrophy. Aside from

this example of primary atrophy, no other was encountered.

Corbett's conclusions are as follows: The histological picture resulting from atresia of the ureter may belong to any one of the following groups: (1) pictures closely resembling nephritis; (2) pictures of fatty change; (3) pictures presenting œdema with a possible suggestion of atrophy. There is no definite proof to show that the changes are mechanical or due to a nephrotoxic substance.

A. C. STOKES.

Pousson, A.: Indications for Operation in Chronic Nephritis (Indications opératoires dans les néphrites chroniques). *J. d'urolog.*, 1913, iii, 717.
By Journal de Chirurgie.

The therapy of chronic nephritis is purely symptomatic and the frequent impotency of medical treatment has caused surgeons to attempt to restrict the spread of the trouble and to remove any mechanical obstruction to function. To overcome the effects of congestion on the kidney with its inelastic capsule, decapsulation and nephrotomy have been performed. Both operations reduce the intrarenal tension. The second, by the abundant hæmorrhage that it causes, relieves the system of a part of the toxins that have accumulated in the blood and thus lessens the vascular tension. It also terminates the capillary paralysis which was preventing serous transudation. Decapsulation should be used in the less serious cases; nephrotomy, when there is serious uræmic intoxication, subcutaneous œdema, oliguria, anasarca, and high blood pressure. The mortality of operation is only 13 per cent. The danger is least in cases of œdema alone, is greater in cases of uræmia either alone or associated with œdema and with oliguria, and is greatest in cases of uræmia associated with oliguria without œdema. From the point of view of permanent relief, the results are best in cases of œdema alone or of œdema associated with uræmia or oliguria. Next best are those obtained in cases of uncomplicated uræmia. Third best are the results obtained in cases of uræmia complicated by oliguria, and fourth, those obtained in cases of uræmia associated with oliguria and œdema.

Indications and contra-indications for operating:

1. Urinary syndrome. This syndrome, the most constant of all, consists in quantitative and qualitative changes in the urine, and the presence in the urine of albumin, cylindrical casts, leucocytes, and red blood corpuscles. Persistent oliguria and diminished salt content are indications for operation; the amount of albumin is not an indication.

2. Choloræmic syndrome. The indications vary according to whether the dropsy is located in the subcutaneous cellular tissue, the large serous cavities, or the viscera. Anasarca is an indication; ascites is not a contra-indication, but hydro-pericardium and hydrothorax and œdema of the lung increase the operative risk.

3. Cardio-vascular syndrome. Myocarditis with dilation of the heart, hypertrophy of the left side

of the heart with a violent beat of the apex and gallop rhythm are contra-indications, as is also Bright's pericarditis. Hypertension of the arteries accompanied by true hypertrophy of the heart is an indication.

Functional troubles of vision due to a slight intoxication of the encephalic nerve centers may be helped by operation, but changes in the optic nerve and retina cannot.

J. TANTON.

Mysch, W. M.: The Surgical Treatment of Chronic Nephritides, Hæmaturica and Dolorosa (Beobachtungen über die chirurgische Behandlung chronischer Nephritiden, Hæmaturica und Dolorosa). *Chir. arch. Veliaminova*, 1913, xxix, 419.
By Zentralbl. f. d. ges. Chir. u. i. Grenzgeb.

In the picture of nephritis new factors must be taken into consideration as the result of the newer diagnostic methods, cystoscopy, ureteral catheterization, functional diagnosis. These new methods have shown that nephritis may be unilateral, that the involvement of the organ may be only partial, that a nephritic kidney may excrete urine free of albumin and casts, and that there are forms of nephritis which are manifested principally by pain (colic nephritis) and by hæmorrhage (nephritis hæmaturica). The three interesting observations of the author belong to the last group.

Mysch had two cases of nephritis hæmaturica and one case of colic nephritis or so-called "nephritis dolorosa." The first case of hæmaturic nephritis was that of a man 24 years of age. On the basis of the pains and findings of a careful cystoscopic examination, and of functional tests, a diagnosis of tuberculosis of the kidney was made. A nephrectomy proved this diagnosis to be incorrect. On careful examination the organ was found to be affected only with chronic nephritis with numerous hæmorrhages into the straight urinary tubules. The patient recovered. In the second case the patient, a woman 53 years of age, was suffering with œdema. Blood was found in the urine. A cystoscopic examination showed that the ureter from which the blood escaped was normal. On the basis of this and other examinations a diagnosis of operative nephritis hæmaturica of the right kidney was made. The operation confirmed the diagnosis and a decapsulation was performed according to the method of Albarran. Complete recovery resulted.

The history of hæmaturic nephritis is associated with the names of Israel, Albarran, and Pousson. The diagnosis of this disease is contingent upon the elimination of all other conditions that are accompanied by hæmorrhage from the kidney. It should be treated by decapsulation and nephrectomy. According to the statistics of Pousson published in 1909, there were no deaths in 6 cases of decapsulation, and four deaths in 12 cases of nephrectomy. The removal of the kidney is indicated only in severe attacks.

The third case was that of a man 28 years of age who suffered from colicky pains. The pains could

be induced also by introducing fluid into the pelvis of the kidney. The trouble was diagnosed as nephritis dolorosa. Calculus, tuberculosis, pyelitis, etc., were excluded by the absence of pathological elements in the urine and by negative X-ray findings. At the operation the kidney was decapsulated and a small piece of kidney tissue was removed for microscopic examination. The patient recovered and was free from further attacks of pain. Microscopic examination showed changes similar to those of severe chronic nephritis. The case, therefore, was the kind of nephritis that is manifested only by colicky pains. This form is seldom observed. Pousson found records of only 14 cases of it in the literature and Kümmell has observed only 10 cases.

SCHAAK.

Ruge: The Present Standpoint in Regard to Nephritis and Nephritis Surgery (Über den derzeitigen Stand einiger Nephritisfragen und der Nephritischirurgie). *Ergebn. d. Chir. u. Orthop.*, 1913, vi, 565r. By Zentralbl. f. d. ges. Chir. u. i. Grenzgeb.

Albumen and casts may at times be demonstrated in the urine of perfectly healthy individuals after severe bodily exertion and must be considered as physiological, depending, according to Leube, upon a hypersensitiveness of the renal filter. Orthostatic and lordotic albuminuria in their pure forms are relatively benign and are probably due to mechanical disturbances and irritation of the renal circulation. By means of powerful massage of the kidney the excretion of albumen, casts, epithelium, and red blood cells may be produced. The disturbances incident to wandering kidneys must likewise be considered as "traumatic nephritis." On the other hand operative findings have proven the interesting fact that even in the absence of any urinary findings definite nephritic processes may exist in the kidney, excluding the well known cases of contracted kidney with intervals of no albumen. The first symptoms of such "nephritis without albumen" are frequently nephralgias and hæmaturia. The opinion at present seems to be that such hæmaturias are due really to chronic nephritis, which is always bilateral. A unilateral nephritis or partial nephritis is possible but rare.

Action of decapsulation: Acute and infectious nephritis shows an injury and swelling of the vessel-bearing connective tissue followed by inflammation and degeneration of the epithelium. The swollen and enlarged kidney is compressed within its unyielding fibrous capsule; the circulation and excretion of urine is interfered with. Decapsulation relieves the tension, and even after complete anuria a marked excretion of urine will follow the operation in cases of acute nephritis. Tissue that has been destroyed of course cannot be replaced as regeneration of kidney epithelium does not occur, but injured cells will frequently recover after the decapsulation. Edebohl believes that a collateral circulation is established between the cortex and the surrounding tissue and that this is particularly marked if the kidney is embedded in omentum. Other writers

deny this and claim that a new dense capsule again develops.

In toxic nephritis, such as that following poisoning with carbolic acid or bichloride of mercury, the kidney should be decapsulated, especially if internal remedies fail. The kidney of eclampsia should be decapsulated in case no improvement follows the emptying of the uterus. In cases of acute nephritis following infectious diseases the kidney likewise should be decapsulated in case internal remedies do not improve the oliguria or the uræmic symptoms. Acute infectious nephritis is of hæmatogenous origin and can usually be differentiated from the ascending pyonephritis. It is usually unilateral and demands a nephrotomy or nephrectomy following ureteral catheterization. In chronic Bright's disease decapsulation has been performed in cases in which no improvement followed a thorough course of treatment. The decapsulation should be bilateral. In a fair percentage of cases clinical improvement results. Decapsulation is followed by improvement in certain cases of uremia due to nephritic anuria or oliguria. Severe hæmorrhages in cases of chronic nephritis not improved by internal therapy should be treated surgically. In addition to the decapsulation a nephrotomy should be done to make sure of the etiologic cause of the bleeding. Decapsulation and splitting up of the kidney should be performed also for nephralgias in which hæmorrhages similar to those of chronic nephritis occur.

OEHLECKER.

Murard: Chronic Nephritides from the Surgical Viewpoint (Les néphrites chroniques au point de vue chirurgical). *Thèse de doct.*, Lyon, 1913, May. By Journal de Chirurgie.

The author has tried to ascertain from the study of the literature and his own experience the rôle of surgery in chronic nephritides, both Bright's disease and the other renal sclerosis characterized by a pain and hæmaturia. The benefit of kidney operations in cases of hæmaturia was discovered by accident and it was thought that even Bright's disease might be cured by surgery.

The author finds that renal intervention is at least innocuous. In the unilateral cases, suppurative and tuberculous kidneys and kidney stone cases, in which the trouble in the other kidney is compensatory, surgery is undoubtedly of great value. Decapsulation has been tried with some success. A capsule is rapidly reformed and there are not enough anastomosing blood-vessels to have any effect on the drainage of the kidney. Nephroepioplasty is not more efficacious. Nephrotomy which is sometimes followed by complete cessation of albuminuria is an important operation.

Murard describes the hæmaturias for which there is no demonstrable cause as hæmaturias of latent nephritis. These are in some cases due to a tuberculosis or a derangement of function in the hæmatopoëtic organs, especially the liver. In these cases decapsulation is not sufficient and nephrotomy is

often only temporary. Renal tumors and continuous hæmorrhage are contra-indications.

Painful nephritis without nephroptosis or renal tuberculosis is more rare than is generally believed. The pain may be due to a perinephritis or Bright's disease or an active localized sclerosis accompanied by inflammatory congestion following trauma calculus or attenuated infection. For this condition freeing of perirenal adhesions and decapsulation, or if there is congestion, nephrotomy is advised.

Operative treatment of Bright's disease is made justifiable only by the importance of medical methods. Nephrotomy may help if there is congestion but as congestion is but a symptom and not a cause of the nephritis it is really of no avail.

G. COTTE.

Blum V.: The Physiology of the Kidneys and the Functional Diagnosis of the Kidneys in Renal Surgery and Internal Medicine (Nierenphysiologie und funktionelle Nierendiagnostik im Dienste der Nierenchirurgie und der internen Klinik). Leipzig and Vienna: Deuticke, 1913.

By Zentralbl. f. d. ges. Chir. u. i. Grenzgeb.

The principal function of the kidney is to maintain for the blood the same osmotic pressure that corresponds to the freezing point of the blood, i. e., 0.56. The osmo-regulating function of the kidney consists of several individual functions chief of which is a water filtration, a salt secretion, and a resorption of some of the water and some of the salts. The urine is a watery solution of organic and inorganic salts which in part are products of metabolism and in part substances which cannot be utilized by the organism. It is the function of the kidney to prevent an accumulation of these salts in the blood which would lead to uræmia.

Injurious substances are excreted as follows: The glomeruli are filters with extensive semipermeable membranes by means of which the blood gets rid of its superfluous water. It is assumed that also at the same time a small quantity of salts are filtered out. The urine in the glomeruli is alkaline. In the convoluted tubules of the first and second order through active cellular activity urinary salts are secreted. Uric acid, acid salts, and phosphates, which are excreted by the tubular epithelium, render the glomerular filtrate acid. In the medulla of the kidney (in the region of Henle's loops and the straight urinary tubules) some of the water and some of the salts are resorbed. In addition to its principal function of maintaining the normal osmotic pressure of the blood, the kidney possesses synthetic functions, such as the secretion of sugar after the injection of phloridzin. It is supposed also that it elaborates an internal secretion. Although careful examinations have shown that both healthy kidneys do not always excrete the same amount of substances of absolutely the same character, this fact does not decrease the value of the functional tests. In performing functional tests each individual function of the kidney should be tested separately: water filtra-

tion, salt excretion, and water resorption. The so-called "topical diagnosis" should be made.

Former methods led only to an anatomical diagnosis of the kidney trouble, and only the total insufficiency could be determined from the oedema, uræmia, cardiac hypertrophy, etc. To-day by means of ureteral catheterization and functional diagnosis the sufficiency and insufficiency of each individual kidney can be determined exactly. Of the methods of functional diagnosis Bouchard's test for the toxicity of the urine and Thudicum's determination of the urinary coloring matter are not of use clinically. On the other hand cryoscopy for the determination of the molecular concentration of the blood and urine according to the method of von Koranyi is of great value. The freezing point of the urine varies even in healthy kidneys to a considerable degree; according to Kümmell and Rumpel, between -0.90° and -2.30° .

Cryoscopy is of particular value because it permits a comparison between the separated urines, and because it can be used in experimental polyuria. Blood cryoscopy is of considerable value in determining the function of the kidney. In normal kidneys the concentration of the blood is constant; the freezing point according to von Koranyi is always -0.56° . According to Kümmell the freezing point of the blood is of considerable value in the prognosis of nephrectomy in cases of unilateral kidney disease. In combination with other functional tests and clinical observations blood cryoscopy in many instances may be the deciding factor. It is easily possible, however, that $\delta = -0.56$ and we would not dare, therefore, to perform a nephrectomy; if, for instance, the halves of both kidneys were diseased and both kidneys were just sufficient to carry on the necessary kidney function blood cryoscopy would yield normal values. A nephrectomy would in this case produce renal insufficiency. Ureteral catheterization, however, would prevent such an error. By means of blood cryoscopy we can measure the osmo-regulating function of both kidneys with exactness.

Albarran's experimental polyuria measures the power of the kidneys to excrete water. Healthy kidneys adapt themselves to increased demand. In artificial polyuria the healthy kidney changes and increases its functional capacity whereas the injured organ as the result of a lack of reserve strength has lost this power either entirely or in part. Another method of testing the functioning of the kidney is to note the excretion of coloring substances that have been injected. The methylene blue of Kutner forms colorless derivatives in the body and is therefore not practical. The indigo-carmin test of Völcker and Joseph is excellent, the coloring matter passing through the kidney almost unchanged and acting similar to a urinary salt. The nature of the excretion therefore allows us to form conclusions in regard to the salt-secreting ability of the kidney.

The indigo-carmin test is of great significance in unilateral affections: a delayed excretion of the

blue substance immediately shows us the seat of the involvement. The phloridzin test has not been found reliable in functional tests of the kidney. The new diastase determination method of Wohlgemuth of the Casper clinic appears to be a good indicator of the functional ability of the organ. The phenolsulphophthalein method of Geraghty and Rowntree is in some respects superior, and in other respects inferior, to the indigo-carmin test. The red color appears only in an alkaline medium; it is a very delicate, almost too delicate, reagent. The value of the method lies in the quantitative determination of the coloring substances excreted.

After a critical review of the methods for functional diagnosis Blum speaks of the attempt at topical diagnosis of the kidney on the basis of functional tests. For the surgical diagnosis ureteral catheterization and radiography have decided many doubtful questions. Before nephrectomy is performed it must be ascertained whether the remaining kidney will be sufficient for the increased work thrown upon it. It is therefore not the momentary function which must be determined but the maximal functional ability, the reserve force of the organ, which is the deciding factor. This is best determined by testing the individual parts of the entire function. The experimental polyuria of Albarran will answer the question as to the water filtration. The urinary excretion, especially the concentration of the indigo-blue excretion, is a valuable indicator for the salt-secreting function of the tubular epithelium. To determine the resorption of water and some of the salts in the medulla, injections of caffeine and diuretic may be considered. Blood cryoscopy shows very exactly the osmo-regulating activity of the kidney. Blum demonstrates very clearly the value of these functional tests in typical cases.

In cases of prostatectomy the author considers it a serious mistake to omit the determination of the functional activity of the kidneys before the operation is performed since success depends so much on the condition of the kidneys. Also before performing a prostatectomy the freezing point of the blood should be determined. In such cases, the phenolsulphophthalein method is a good one to use in determining the functional activity of the kidneys. The operation should be postponed if the beginning of the excretion is delayed beyond twenty-five minutes and if the quantity of salt excreted during the first hour is less than twenty per cent. In conclusion the author points to the value of determining the functional activity of the kidneys in medical cases. The slip-shod method of diagnosing "nephritis" should be supplanted by modern diagnostic methods based on topical functional tests.

OEHLCKER.

Bryan, R. C.: The Early Diagnosis of Renal Tuberculosis. *N. Y. M. J.*, 1913. xcviii, 20.
By Surg., Gynec. & Obst.

Bryan emphasizes the cardinal features of the diagnosis, the pitfalls, errors and elusive symptoms

of the incipient stage of miliary tuberculosis of the kidney, and selects from his series the histories of three cases for deductions.

He finds that uranalysis is inconstant in the character of its results, and gives evidence of a more or less severe nephritis; the urine is of low specific gravity; the reaction is regular and constant; pus, the characteristic index of invasion, is intermittent; the few cells, in the regularly acid urine, are a clue for diagnosis which is especially valuable if stone can be positively excluded; albuminuria is unilateral; pollakiuria is noted peculiarly during the night but is not marked during the day.

All voided urine should be collected, preferably in a Steinbeck's sedimentator, and preserved with boric acid, one grain to the ounce of urine. Repeated examinations of the sediment are advised.

Cystoscopy shows a fluffiness, blueness, and an injection of the ureteral opening; the tuberculin or T. R. test, von Pirquet's reaction of the skin and Calmette's reaction of the conjunctivae may be used for corroboration, but must be conducted with great caution. Injection of the sediment into the peritoneal cavity of the guinea pig is an efficient measure. Phenolsulphophthalein should be used to ascertain unilateral efficiency.

LOUIS GROSS.

Desnos: A Contribution to the Clinical Study of Strictures of the Ureter; Large Strictures (Contribution à l'étude clinique des rétrécissements de l'uretère; rétrécissements larges). *J. d'urolog.*, 1913, iii, 739.
By Journal de Chirurgie.

Strictures of the ureters may be due to trauma caused by the migration of a renal calculus or to more or less limited regions of ureteritis. These lesions after a time cause a cicatricial process which decreases the lumen of the ureter. The author has recently observed four such cases, two following slow, painful migration of calculi, and two following a previous vesical infection.

The symptoms are not pathognomonic. The strictures manifest themselves rather by the complications that they cause. These complications are a greater or less degree of renal retention with pain in the upper urinary passages, continuous or with exacerbations, and an exaggeration of the infection of the urinary tract. Accordingly ureteral stricture is to be suspected when the above symptoms are present without apparent cause, and especially when the ureteropyelitis becomes rapidly worse. A relatively slight stricture may cause considerable renal retention. Ureteral strictures may cause also reflex symptoms, a uretero-ureteral reflex in particular, which may be confusing.

Certain diagnosis can be made only by ureteral catheterization by means of a ureteral bougie. If the strictures are relatively new, dilatation by ureteral sounds allowed to remain in a while may be sufficient. In this way may be avoided the necessity for external ureterotomy, but the latter is the best method when dilatation of the stricture is impossible.

J. TANTON.

BLADDER, URETHRA, AND PENIS

Barney: A Case Illustrating the Efficiency of the High Frequency Current in the Treatment of Tumors of the Bladder. *Boston M. & S. J.*, 1913, clxix, 19.
By Surg., Gynec. & Obst.

The writer reports a case of apparently complete cure of a tumor of the bladder by means of the high frequency current. Cure was effected in nine sittings at intervals of one or two weeks. Owing to the appearance of the bladder wall at the site of the tumor at the last sitting, it was believed that the growth was cancerous. Suprapubic cystotomy showed the suspected area to be reddened, œdematous, and brawny, with a few small ulcerations and a generally rough surface. Careful study of the excised specimen by two competent pathologists failed to find any tumor cells. Cystoscopic examination of the patient nine months later showed no evidence of recurrence.

In regard to the misleading appearance of the bladder wall the writer quotes Keyes, Jr., who says: "It is a curious reaction of the bladder wall to the irritation of the current. The mucosa swells up in such a way as to simulate an infiltrating carcinoma. Several weeks' intermission in the burning will suffice for the subsidence of this."

So far as is known, no other case of bladder tumor treated and presumably cured by the high frequency current has yet been actually inspected at a subsequent time, either at operation or post-mortem. This method of treatment is, therefore, in certain cases of non-malignant growth, entirely effective.

Stevens: Diagnosis and Treatment of Multiple Urethral Calculi, with Report of Unusual Case. *J. Am. M. Ass.*, 1913, lxi, 86.
By Surg., Gynec. & Obst.

The author reports one case of multiple urethral calculi. After demonstrating the absence of stones from the kidneys, ureters, bladder, and prostate, and the normal condition of the kidneys, he concludes that the stones had formed in the urethra. He removed all by intra-urethral instrumentation.

In discussing this condition Stevens draws a distinction between calculi originating elsewhere in the urinary tract than the urethra and simply lodging there while being passed and those which form there primarily. The latter are caused by the deposition of urinary salts in abnormal pockets, such as are formed by strictures and diverticula.

GEORGE G. SMITH.

Jordan: Congenital Stricture of the Prostatic Urethra with Bladder Hyperplasia, Urethral Dilatation and Multiple Abscesses of Both Kidneys. *J. Am. M. Ass.*, 1913, lxi, 244.
By Surg., Gynec. & Obst.

The author reported a congenital prostatic stricture, which is exceedingly rare. The treatment proved unsuccessful; his patient died at the age of seven weeks, having been under observation three weeks. The post-mortem examination showed a

stricture of the prostatic urethra, one fourth inch in length. The kidneys were enlarged, cystic, nodular, and showed a chronic diffuse nephritis. The ureters were large and sacculated. The bladder was small, the walls being composed of dense fibrous tissue.

C. D. PICKRELL.

GENITAL ORGANS

Belfrage: Traumatic Total Loss of Skin of the Male Sexual Organs (*Evulsio cutes totalis genitalium virilium*). *Nord. med. Ark.*, 1913, xlv, 11.
By Zentralbl. f. d. ges. Chir. u. i. Grenzgeb.

Belfrage reports a case in which through traumatism there was a loss of the entire cutaneous covering of the penis and scrotum. The penis was covered with Thiersch grafts from the forearm, and the testicles were transplanted beneath the skin of the abdominal wall. The result was quite satisfactory. The transplanted skin on the penis was freely movable. The testicles were not fixed under their cutaneous covering, and not exposed to pressure, so that there was no interference with the sexual functions.

The author discusses the methods employed by others in similar cases and concludes that the Thiersch graft is the proper procedure for covering the penis. Where there is entire loss of scrotal skin the Thiersch method may be used, or the neighboring skin may be utilized as a plastic flap, or, lastly, the author's method of transplanting the testes may be employed.

DENCKS.

Carless, A.: A Case of Perineo-Scrotal Dermoid Cysts. *Brit. J. Surg.*, 1913, i, 39.
By Surg., Gynec. & Obst.

Examination in the case of a boy 12 years of age revealed two subcutaneous swellings in the perineum which had been present since birth and were slightly increasing in size. One of them was situated in the posterior part of the scrotum and the other at the anterior extremity of the perineum. Extending backwards from behind the two swellings was a narrow median intradermic passage or track which reached as far as the anal margin. A stream of the cyst contents could be seen rippling along the passage in the perineal raphe. Rectal examination was negative. The penis and urethra were normal. The diagnosis made was perineal dermoids with extension backwards along the raphe. The cysts and the narrow perineal canal were removed by dissection with satisfactory result.

The interest in the case lies mainly in the existence of the perineal tube.

In this connection the author cites a somewhat similar case reported by Edington of Glasgow. The patient, a boy two days old, with an imperforate anus, had a perineal tube that communicated with the bowel.

The author believes that pathological conditions of this kind are the result of an error in the development of the external genital folds. DROZDOWITZ.

Bucklin: Castration and Operation for Varicocele and Hydrocele Without Wounding the Scrotum. *Med. Rec.*, 1913, lxxxiv, 108.

By Surg., Gynec. & Obst.

The author has had 30 years' experience with the anterior scrotal incision in operations upon the testicles and cord, and has had frequent failures, primarily because the incision did not expose the diseased tissues sufficiently to allow of thorough examination. He is now firmly converted to the transverse inguinal incision of Kocher in all operations upon these parts.

While advocating castration for all malignant growths in tuberculosis of the testicles, he is in favor of attempting to cure the tuberculous developments by the administration of one tumblerful of pure sterilized milk every 36 minutes for 12 hours, followed on retiring by a sufficient dose of fresh castor oil. Three months' trial of this treatment is given before resorting to castration. An increase of weight contra-indicates castration.

In hydrocele, Kocher's operation is advocated. The author states that this procedure produces a cure in every case and leaves the testicle surrounded by its normal coverings.

A. NELKEN.

Tait: Recurrence of Hydrocele after Radical Treatment. *Cal. St. J. Med.*, 1913, xi, 258.

By Surg., Gynec. & Obst.

Tait claims there is a tendency of late to return to the operation of total resection, as there are so many recurrences following eversion. Errors in technique and choice of operative procedures, besides the numerous modifications of a good operation (Longuet), have caused these recurrences. From his animal experimentation he is convinced that the protective rôle of the tunica vaginalis, like that of other serous membranes, has been greatly overestimated.

The procedure he follows is the operation perfected and simplified by Longuet in 1900; in this method he does away with all dissection, omitting the delivery of the tumor and making a new bed for the testicle.

Tait divides the recurrences into three groups: In the first small group the operation of eversion was done without securing the everted tunic. In the second group the opening in the tunic was smaller, but here again no suturing was done; this constitutes the widely heralded Andrews bottle operation, which its author in 1907 and again in 1912 recommended without reserve and urged "that it supersede all other operations for hydrocele." In the third group of recurrences the cases of hydrocele are due to subacute infections, tuberculosis of the epididymis, and chronic pachyvaginitis.

Among the results of these experiments (eversion, resection, injection of irritants) on animals, he found the following:

Infection of the tunic is invariably followed by a marked change in the testicle, reduction in size, sclerosis, and peripheral areas of atrophy. Under

strictly aseptic conditions eversion is not followed by atrophy of the testicle. The testicular sclerosis is not more marked after eversion than following the injection of irritants into the tunic. Excision of the tunic gives rise to more marked testicular reaction than does eversion. That the function of neither the interstitial nor the spermatogenic cells is affected by bilateral eversion of the tunica vaginalis is sufficiently proved by the total absence of the developmental abnormalities in and the multiplication of puppies after said operation. It would seem, nevertheless, that the testicle is no exception to the law of general pathology relating to the creation of points of lessened resistance by traumatism or infection.

The author reaches the following conclusions:

1. Although eversion is only a palliative measure, it will, when properly performed, prove satisfactory in over 90 per cent of hydroceles.

2. Longuet's method, *without delivery of the sac*, is the simplest, safest, and least liable to recurrence.

3. Recurrence frequently results from failure to stitch the edges of the everted tunica vaginalis.

4. Andrews' bottle operation is a failure; its adoption accounts for a large proportion of the recurrences.

5. Excision is preferable to eversion in the rare cases of chronic pachyvaginitis.

6. Excision of the unopened hydrocele is the only complete method of removing the entire excreting surface.

7. Of the numerous objections made by conservatives to the radical treatment, none resists either a thorough clinical or experimental test.

8. The protective rôle of the tunica vaginalis has been overestimated.

9. Under strictly aseptic conditions experimental eversion of the tunic is not followed by atrophy of the testicle; it may produce a mild peritesticular sclerosis.

LOUIS GROSS.

Eccles, W. M.: Ectopia Testis. *Clin. J.*, 1913, xlii, 241.

By Surg., Gynec. & Obst.

The author names five positions in ectopia testis: Perineal, femoral, superficial inguinal, cruro-scrotal, and prepenial.

As etiology, he mentions "the pull of the lateral fibers of the gubernaculum attached to spots away from the normal, and the push of an advancing hernia."

The most common position is between the anus and the tuber ischii. The ectopia testis is not necessarily an imperfect organ; in the perineum it may be fairly well developed and quite capable of producing spermatozoa. In other positions, however, it is generally imperfect.

As treatment, Eccles mentions transplantation wherever feasible. This is usually possible when the ectopia is situated on the perineum. When the ectopia testis is improperly developed, it is usually accompanied by a hernia, and should best be removed.

Ectopia testis is subject to inflammation which, particularly in the perineum, may be either traumatic or infectious. Inflammation in the perineum may simulate an ischio-rectal abscess. When ectopia testis is associated with a hernia, an operation is always advisable, particularly for the hernia. The testis may become the site of a new growth.

Stevens, A. R.: On the Value of Cauterization by the High Frequency Current in Certain Cases of Prostatic Obstruction. *N. Y. M. J.*, 1913, xcvi, 170. By Surg., Gynec. & Obst.

Stevens reports two cases in which he successfully applied Beer's suggestion of cauterizing by the high frequency current for the relief of prostatic obstruction.

One case of contracture of the vesical neck with twenty-six ounces of residual urine and nocturnal enuresis was cauterized six times by means of the Oudin current for a total of eighteen minutes. The residual urine was reduced to one and a half ounces. In a case of middle-lobe prostatic obstruction, with fourteen ounces of residual urine, the Oudin current was applied six times for a total of nine and one half minutes. The residual urine was reduced to a half ounce. The treatments were tolerated so well that no anæsthetic was used. Moreover, they did not interfere with the patients' business and were not followed by pain or serious bleeding.

Cauterization by high frequency current is not suitable for large prostates but will probably prove efficient for constriction of the vesical neck and for median bars or lobes and single lobes that project into the bladder or urethra from any other portion of the prostate.

J. B. CARNETT.

Gebele: Carcinoma of the Prostate (Über das Prostatacarcinom). *Zentralbl. f. d. Grenzgeb. d. Med. u. Chir.*, 1913, xvi, 579.

By Zentralbl. f. d. ges. Chir. u. i. Grenzgeb.

Carcinoma of the prostate is a relatively frequent disease. Macroscopically a carcinomatous prostate is frequently abnormally small; at other times the infiltrated tissue comprises a tumor that fills the entire pelvis. Its consistency is usually hard. Its surface may be nodular or smooth. The tumor is usually an adenocarcinoma; more rarely it is scirrhous. In most instances it is primary in the prostate. Secondary tumors are found most commonly after gastric tumors.

The so-called osteoplastic carcinoma of the prostate consists of small nodules, hard and primary in the organ, with numerous metastases in the form of diffuse infiltration in different bones. The bones of the pelvis, the lower portion of the spine, and the bones of the lower extremity are most commonly involved. Prostatic hypertrophy seems to predispose to carcinoma. The early diagnosis can be only probable. If a small, hard prostate is palpable per rectum, carcinoma must be suspected. The other symptoms are variable. The prognosis is unfavorable. Advanced cases can be treated

only symptomatically or a palliative operation may be performed. Some authors do not deem a radical removal advisable even in the early stage. The methods of operation are variable: suprapubic, perineal, or combined. In case the bladder and seminal vesicals are involved the author advises the method of Völcker: ischio-rectal incision with the patient in the abdominal position. The statistics of the operative results are bad. As permanent results are reported continually, however, the attempt may be made to effect a radical removal of the carcinoma unless the case is far advanced.

DENCKS.

Willian, R. J.: Carcinoma of the Prostate Gland. *Brit. M. J.*, 1913, ii, 60. By Surg., Gynec. & Obst.

The author quotes Albarran's statistics as proving that 14 per cent of all prostates removed by operation show malignancy, and Young as saying that 21 per cent of all enlarged prostates are malignant. As a basis for his paper, Willian has collected notes on 33 cases of carcinoma of the prostate. He does not state how many, if any, of the series were operated upon. He advises operation for the actual diagnosis of carcinoma. If carcinoma is present, radical cure probably cannot be effected by operation. The author's summary reviews the paper:

1. The average duration between the onset of symptoms and the time that the patient saw the surgeon was fourteen and one half months.

2. The average age was 61.

3. The onset symptom was nocturnally increased frequency of micturition in 40 per cent, and gradual obstruction of micturition in 30 per cent of the cases.

4. Pain was variable and not characteristic.

5. Urinary obstruction was a marked feature; 72 per cent had complete retention, and a further 24 per cent, partial retention.

6. Hæmaturia was not common: probably 82 per cent did not show blood.

7. On rectal examination, 70 per cent showed hard nodules with fixity of the gland.

8. The average duration of the disease from the onset of the symptoms to death was 28 months.

9. Young's statistics that 20 per cent of removed prostates show a malignant tendency cannot be ignored. If these figures are accepted, it is the surgeon's duty to remove the gland by operation as soon as it begins to cause symptoms. The risks of the operation are at that time smaller than the risks after malignancy has developed.

10. The treatment recommended when a diagnosis of carcinoma has been made is as follows:

(a) In the absence of residual urine, give a urinary antiseptic, with opium for the pain when necessary.
(b) If there is residual urine, begin catheter life, using a large-sized hard catheter; give a urinary antiseptic, with opium if necessary.

(c) If there is obstruction, or if catheter life is intolerable, establish a permanent suprapubic drainage.

M. S. HENDERSON.

Wallace, C.: Some Conditions Simulating Prostatic Hypertrophy. *Clin. J.*, 1913, xlii, 209.

By Surg., Gynec. & Obst.

The author reports six cases which simulated prostatic hypertrophy but proved not to be.

One interesting case was that of a small projection which on removal brought with it a strand of mucous membrane and fibrous tissue from the posterior urethral wall. The strand contained several minute adenomata.

The second case was operated upon but no enlargement was found. The bladder was drained and eventually allowed to close, without any resulting benefit. Then, although it was considered to be a case of secondary atony, the bladder was reopened and a wedge-shaped portion of normal prostate was removed. The apex of the wedge lay about half an inch behind the urethra, and the base corresponded to the posterior wall of the urethra above the ejaculatory ducts. That normal micturition was restored indicated to Wallace that the symptoms were due to an anatomical defect.

The author claims that in cases of this kind micturition is obstructed not by a bar but by a bending of the urethra within the prostate. A diagnosis of "vesical prostatism" should be made with great reserve.

Conclusions: (1) That many cases present symptoms which at first might reasonably be considered to be caused by prostatic hypertrophy, but which subsequent examination will prove to be due to other causes; (2) that prostatic enlargement can be excluded only by a bimanual examination through the opened bladder; (3) that even when a bimanual examination proves that there is no enlargement the cause of the errors of micturition may still lie within the prostate; (4) that no error of micturition should be assigned to a failure of nerve or muscle until all mechanical defects have been excluded; (5) that at least in some cases, the cause of difficult micturition is a bending of the prostatic urethra, and the patient can be cured by a simple operation.

LOUIS GROSS.

Hagner and Fuller: The Post-Operative Complications of Prostatectomy. *Surg., Gynec. & Obst.*, 1913, xvii, 110.

By Surg., Gynec. & Obst.

A study of the post-operative complications offers a field of instruction to the surgeon for his future benefit. The important complication is hæmorrhage, usually of venous origin. It occurs within forty-eight hours and is controlled by pressure with gauze soaked with adrenalin. The removal of the perineal drainage tube is facilitated by the use of oil and peroxide. If the bleeding is suprapubic, a catheter is passed through the urethra into the bladder. The bladder end of the catheter has a knot of gauze which serves as a plug. It can be easily removed by passing a suture through the bladder end of the catheter and carrying it out through the suprapubic wound.

Thrombosis, especially of the pulmonary vessels,

is an infrequent complication. Sudden death may, however, be due to this condition. As pneumonia has to be guarded against, great care should be exercised in administering the anæsthetic. The author uses nitrous oxide and oxygen at present. Sepsis occurs less frequently in the perineal operation due to better drainage. When sepsis does take place, good ample drainage and continuous irrigation is of inestimable value. The intravenous injection of salt solution and the use of vaccines are also of value.

The kidney function should be tested before operation if there are any signs of renal disease, using Geraghty's phenolsulphophthalein test. Pyelitis and uræmia must always be looked for in these cases. If present, one should use salt solution, sweating, and other appropriate measures. The prognosis in cases with diabetes is proverbially bad. A continuation of pyuria after operation is due to infected kidneys, a long-standing, pre-existing cystitis, or to diverticula. A thorough digital examination of the internal urethra should be made at the end of the operation to determine that no diverticula has been left, as this may necessitate a secondary operation. Post-operative urinary frequency is the result of a contracted bladder or loss of control.

The peritoneum should not be torn as it may lead to peritonitis. The rectum should be carefully watched as fistulæ follow when it is ruptured. For the same reason silk traction sutures are not used. The infection travels along the suture. The fistulæ are usually mild and readily yield to treatment.

No operation gives more relief to a patient than a properly performed prostatectomy; hence the importance of pre-operative and post-operative care of the patient. Cystoscopic examination should be made to ascertain what, if any, complications exist and the best way to operate.

Grinenko: Total Prostatectomy in the So-Called Prostatic Hypertrophy (Über die totale Prostatektomie bei der sogen. Prostatahypertrophie). *Disser-tation*, St. Petersburg, 1913.

By Zentralbl. f. d. ges. Chir. u. i. Grenzgeb.

The author conducted investigations on the cadaver to determine whether the prostate had a capsule of its own which would make complete enucleation possible. It was found that the gland possesses only one layer of fascia, which is smooth on the external surface posteriorly only and rough on the other surfaces of the gland. This fascial covering can be separated from the gland easily on the posterior surface, with the exception of the median part, and also on the sides. On the anterior surface it can be separated only with difficulty. A continuation of the fascia to the apex and to the base of the gland was not demonstrated and it was impossible to isolate a distinct capsule. The capsule described by other authors must be considered as a part of the pelvic fascia which invests the entire gland with the exception of the base and apex.

The division of the prostate into distinct lobes is not justified from an anatomical point of view. To determine whether a gradual increase in size of the gland takes place with advancing age, the author examined the prostates of sixty male cadavers between the ages of 40 and 90 years and arranged them into groups according to age. It was found that the size of the gland increases only a trifle with advancing years. On the strength of thirty-two cases examined, he comes to the conclusion that prostatic hypertrophy is a tumor formation (adenoma) of the glandular tissue. The principal changes occur in the central part of the gland, directly under the urethral mucosa. The author then offers microscopical proof of his contention. From the clinical standpoint his views are reinforced by the progressive character of the disease, by the occurrence of malignant degeneration and by the possibility of recurrence.

The author offers further evidence that these adenomas originate in the periurethral glands. Although the prostate grows in size it retains its normal contour; the enlargement is at the expense of the antero-posterior diameter. The glandular tissue of the prostate is divided by the smooth sphincter internus into a central and peripheral part of periurethral glands. With the enlargement of the periurethral glands the sphincter internus is forced backward. The peripheral zone is the true prostatic glandular tissue. The musculature of the prostate and the musculature of the pars prostatica urethræ are really inseparable, being practically one. On account of this musculature a close relation exists between the prostate and its surrounding structures.

As a result of his operative experience and investigations on the cadaver, the author comes to the conclusion that a complete extirpation of the prostate in the histological sense is impossible without causing a lesion of the pelvic fascia and ejaculatory ducts. The adenomatous enlargements of the prostate are much more accessible from the bladder than from the perineum. During a prostatectomy the entire gland is not enucleated but only its adenomatous part. In the living man a large part of the gland remains intact which may be considered as the surgical capsule and which prevents the opening of the preprostatic venous plexus and of the pelvic connective tissue. Experience teaches further that in view of the close relationship of the urethral mucosa to adenomatous tissue, a part of the former is sacrificed at the prostatectomy. The ejaculatory ducts as a rule remain intact during the removal of the adenomatous masses. The author prefers the transvesical route to the perineal for the following reasons: Technically the operation is easier; hæmorrhage is less; thorough drainage from the wound is obtained; and in infected cases and in old individuals the operation may be performed in two steps. Above all, the excellent results obtained by it favor the suprapubic route. An extensive bibliography and four microphotographs are appended.

HESSE.

Moore: Prostatectomy in the Aged. *Interst. M. J.*, 1913, xx, 648.
By Surg., Gynec. & Obst.

The author submitted a series of questions to the genito-urinary surgeons in this country and abroad with reference to their experience in prostatectomy in the aged. From the answers received he compiles the following:

Twenty surgeons reporting successful perineal prostatectomies gave the highest age of their patients as ranging from sixty-three to eighty-nine years. Twelve had operated successfully on men over eighty, reporting, in all, thirty cases between eighty and ninety.

Eighteen surgeons reported successful suprapubic operations upon patients whose ages were from sixty-six to ninety. Thirteen of these had operated successfully upon men over eighty, reporting fourteen cases.

Of the twenty-five surgeons who expressed an opinion, all but five were in favor of prostatectomy in the aged where general conditions are satisfactory and local conditions indicate an operation.

The mortality of less than two per cent following prostatectomy, in the absence of serious complications, is contrasted with a death rate of over five per cent for enlarged prostate treated by catheterization.

The author reports two cases of perineal prostatectomy in patients ninety years of age, in which his results were prompt and satisfactory. He concludes that catheter treatment of enlarged prostates is unsurgical and unsafe; that prostatectomy is the best treatment; that it is nearly as safe in the very aged as in younger men; and that it is the consensus of opinion that age is no bar to prostatectomy and the operation should therefore be performed whenever practicable.

THOMAS C. HALLOWAY.

Pfister: Urolithiasis and Bilharziasis (Urolithiasis und Bilharziasis). *Arch. f. Schiffs- u. Tropenhyg.*, 1913, xvii, 309.

By Zentralbl. f. d. ges. Chir. u. i. Grenzgeb.

Until now the views held in regard to the direct relations between bilharziasis and the frequent occurrence of stone in the urinary passages have been divided; one group of men maintaining that all stones in the urinary passages are due to bilharziasis, and the other group maintaining that the increased amount of mineral matter in the water of the Nile during the summer is responsible. The fact remains, however, that those investigators who examined a large number of stones found bilharzia eggs in their centers much more rarely than was expected.

Pfister calls attention to the fact that frequently little nodules are found in the center of stones. These nodules are the result of drying and calcification of the fluid present in the small cystic bodies found in cystic cystitis of bilharziasis. Furthermore, these little nodules found in the so-called

"sandy bladder" are the result of calcification of little ulcers resulting from penetration of these little eggs into the bladder. Therefore we must also consider stones containing such little nodules as due to bilharziasis. In thirty stones carefully examined along modern lines, Pfister found bilharzia eggs only three times positively; in three instances bilharzia eggs were probably present. Other interesting points are discussed, tending to show that in Egypt a bilharzia infection predisposes to stone formation.

RUBRITIUS.

Freund, E.: Experiences with Arthigon in Complications of Gonorrhœa (Erfahrungen mit Arthigon bei den Komplikationen der Gonorrhœa). *Wien. med. Wchnschr.*, 1913, lxiii, 1550.
By Zentralbl. f. d. ges. Chir. u. i. Grenzgeb.

The author treated 23 cases of acute gonorrhœal epididymitis with injections of 0.5 gm. of arthigon and obtained good results in 21 cases. In one case of chronic epididymitis four injections had no effect. Seven cases of acute prostatitis were promptly cured. In five cases of chronic prostatitis and three of anterior gonorrhœal urethritis the injections gave no results. One case of posterior gonorrhœal urethritis and lymphangitis was considerably improved by two injections. Also two cases of gonorrhœal arthritis were influenced favorably. Forty-two cases were treated in all.

Freund's conclusions are as follows: 1. Arthigon is a specific remedy of great diagnostic value in doubtful cases. 2. It is perfectly harmless. 3. It is of great therapeutic value in acute gonorrhœal epididymitis, acute gonorrhœal arthritis, and sometimes in acute gonorrhœal prostatitis. Especially in epididymitis the vaccine therapy is superior to all other known methods and remedies, because it relieves the patient immediately and shortens the time of treatment for the entire gonorrhœal affection. According to the recommendations of Bruck, Freund treated only those cases in which there was no fever. Numerous other authors have reported favorable results with this therapy. MAGENAU.

Kolischer, G.: Mid-Operative Diagnosis in Urologic Operations. *J. Am. M. Ass.*, 1913, lxi, 174.
By Surg., Gynec. & Obst.

The object of this paper is to emphasize the importance of mid-operative diagnosis in urological operations after the organ has been exposed, and the fact that operative procedures must often be adjusted to the conditions discovered.

In most instances of external urethrotomy it is impossible to decide definitely whether to perform a mere splitting operation or to resect until the urethra is exposed.

In Hagner's epididymotomy the location and the extent of the depleting incisions cannot be decided

upon until the testicle and its appendages have been fully exposed to view and a palpatory examination has been made. The same holds good for tuberculosis involving the epididymis.

In suprapubic prostatectomy the macroscopic differential diagnosis between simple hypertrophy and cancer, and between hypertrophy and an œdema of the prostate, cannot be made until the bladder is opened.

In cases of extensive tumors of the bladder, especially those in which the tumors are near the base of the viscus, and in which extensive resection or a complete extirpation of the bladder is contemplated, these questions can be decided best by exposing the bladder, digging it out of its surroundings without opening it, and in this way making it accessible for immediate palpatory examination.

In kidney surgery the mid-operative diagnosis is of great help. Unusually free hæmorrhage in the approximating incision will call the attention of the operator to the presence of adhesions and the possibility that the causative inflammation has involved the peritoneum and glued it to the kidney. The operator should therefore use extreme caution not to break into the serosa. Any œdema discovered surrounding the ureter on its course down to the bladder is as a rule of mechanical origin and indicates that the ureter is kinked. The ureter, therefore, will have to be exposed and the obstruction removed before its patency can be re-established.

Bimanual palpation of the exposed kidney will in certain cases furnish information which is absolutely decisive as to the choice between nephrectomy and nephrotomy. This decision can be made before the kidney is opened. For instance, in coli or streptococci infections of the kidney involving a small area, especially those located in the neighborhood of the pelvis, the chance of cure by drainage is good. On the contrary, if palpation of an enlarged kidney infected by the colon or the streptococcus bacillus reveals the presence of numerous sclerosed spots and a number of softened areas, an extensive hard infiltration of the renal parenchyma, or a fluctuating sac, the kidney should be removed unopened.

In cases of renal concretions a combined palpation of the exposed kidney will be of great advantage. After splitting open the renal pelvis it will enable the surgeon to explore the calices and locate concretions higher up in the parenchyma and will also facilitate the sounding of the ureters.

In perineal suppurations the mid-operative diagnosis will influence the diagnosis between an infected perineal hæmatoma or a superficially infected focus in the surface of the kidney.

In conclusion the author covers some of the most important points in which mid-operative diagnosis will show its value in urological work.

THEO. DROZDOWITZ.

SURGERY OF THE EYE AND EAR

EYE

Ohlemann: Severe Injuries to the Eyes and Face by So-Called Water-Core and Zodiac Golf Balls; Methylalcohol and Golf Balls (Augen- und Gesichtsverletzungen schwerer Art durch sogenannte Water Core- und Zodiac-Golfbälle oder Methylalkohol und Golfbälle). *Klin. therap. Wchnschr.*, 1913, xx, 604.

By Zentralbl. f. d. ges. Chir. u. i. Grenzgeb.

The author points out the fact that the rubber core in the above-mentioned golf balls is replaced by a cheap fluid or cement-like, sour or alkaline reacting mass which is under high pressure, and the chemical composition of which is a trade secret. If a ball of this kind is opened in any way, its contents explode violently and injure the hands, face, and clothing of the bystanders just as would any corrosive fluid. Two hours later the eyeballs are greatly swollen, and reddened, the conjunctiva of the lids as well as the bulb is converted into a dirty grey mass and the cornea, with the exception of its upper part, becomes opaque and milky. There is marked chemosis and diminished vision. After two weeks iridocyclitis with hypopyon and necrosis develops in the lower quarter or third of the cornea, which is covered with superficial blebs. The episcleral tissue later becomes pale, scarred, and densely opaque. In eyes injured by zodiac balls, the cornea becomes clearer after the use of dionine, atropine, holocaine, and subconjunctival injections of physiological salt solutions. This is not the case in eyes struck by the water-core balls. In the latter the opacities of the cornea are permanent. Because the extremely dangerous methylalcohol has so often been smuggled in under another name in spite of the law, the author assumes justly that the balls mentioned, which are produced in America, may be introduced into Germany. He therefore warns against the use of them.

VON SAAR.

Stephenson, S.: Some Remarks upon the Diagnosis and Treatment of Lacrimal Affections. *Clin. J.*, 1913, xlii, 252. By Surg., Gynec. & Obst.

Stephenson says that we do not now at once assume that a watery eye is the result of an organic stricture, as was at one time the case. A surgeon eliminates such causes of epiphora as a displaced or occluded punctum or a chronic nasal catarrh. If no obvious cause is found, fluorescein is dropped into the conjunctival sac to see if it will pass into the nose. Treatment of the conjunctival sac and nose should be carried on for several weeks, and if this fails, a lacrimal syringe may be used. Even if fluid does not pass through at the first few trials it is probable that this plan will succeed *if the condition has not been treated by probing.*

Stephenson warns of the danger of using argyrol or protargol under pressure. If the syringe is of no avail, use may then be made of the probe, or the sac may be extirpated, or Toti's operation may be performed. A discussion of these measures follows.

C. G. DARLING.

Stephenson, S.: Clinical Lecture on the Treatment of Glaucoma, with Particular Reference to the Newer Operations. *Med. Press & Circ.*, 1913, xcvi, 58. By Surg., Gynec. & Obst.

Stephenson takes up the treatment of glaucoma under three headings: (a) first aid; (b) surgical aid; (c) palliative treatment. Under first aid he discusses subconjunctival injection of sodium-citrate, posterior sclerotomy, pilocarpine, and dionin. Under surgical treatment he discusses iridectomy and its modifications, Lagrange's, Elliot's, Heine's, Heine-Fergus', Bettremieux's, the Thread, Herbert's and Holth's operations in detail. He does not think that palliative treatment should be long continued.

C. G. DARLING.

Frenkel, H.: Capillary Angioma of the Retina. *J. Ophth., Otol. & Laryngol.*, 1913, xix, 268.

By Surg., Gynec. & Obst.

Frenkel reports a case of his own of capillary angioma of the retina, and reviews the similar cases which have been published.

In reviewing his own case he says: "The question is that of the origin of capillary angioma of the retina characterized by the occurrence in locations more or less distant from the papilla of little spots, bright in this instance, in the place where the retinal capillaries are presumed to be. These little spots are situated between an afferent and an efferent vessel. Gradually they increase in size and at the same time the vessels between which they occur become more apparent. Then we can perceive that as the bodies become larger there is a corresponding exaggerated development of the arteries and veins which are dilated, turgescient, tortuous. At this stage we can see more than two vessels abutting upon the same body even as two bodies may communicate by intermediary dilated vessels.

"This affection begins very insidiously, provoking at first subjective troubles — a sensation of smoke before the eyes, mist, muscæ volitantes and, finally, at the end of several months or maybe a year, a lowering of visual acuity. Objective scotomata have been noted at the periphery of the visual field, it is true with some difficulty. In one case they developed simultaneously in the two eyes.

"As antecedents, we find a sister blind in both eyes at the age of 15 and 18 years. The patient's

affection began after his military service, at the age of about 23 or 24 years.

"The ophthalmoscopic appearance at this stage of the disease is very characteristic and is similar to figures of analogous cases published in ophthalmic literature."

C. G. DARLING.

Verhoeff, F. H.: Parinaud's Conjunctivitis; A Mycotic Disease Due to a Hitherto Undescribed Filamentous Organism. *Arch. Ophth.*, 1913, xlii, 345. By Surg., Gynec. & Obst.

The findings reported in this article are well given in the conclusion: "In eleven out of twelve consecutive cases, each having the clinical features described by Parinaud and each presenting essentially the same characteristic histological picture, a minute filamentous micro-organism was found. The absence of any other demonstrable micro-organisms in the lesions, the unusual character of the micro-organisms found, their great abundance and the fact that they were so situated as to explain the lesions, leave no reasonable doubt that they were the cause of the disease. Their occurrence in the areas of cell necrosis previously pointed out by me confirms the diagnostic importance of these areas."

The clinical findings in all the cases consisted of conjunctival granulations with smaller or larger white areas on their surfaces and the enlargement of the pre-auricular lymphatic gland. Histologically in all of these cases focal areas infiltrated with endothelial phagocytes in various stages of necrosis were found. These cells were discrete in arrangement. There were few lymphoid and plasma cells and almost no pus cells. The organism was made visible by staining with a modified Gram stain which is described in the article. EARLE B. FOWLER.

Hirsch, C.: Sympathetic Nystagmus in Erysipelas (Sympathischer Nystagmus bei Erysipel). *Deutsche med. Wchnschr.*, 1913, xxxix, 315. By Zentralbl. f. d. ges. Chir. u. i. Grenzgeb.

Spontaneous nystagmus, mostly horizontally rotatory, with eyes directed laterally or up and down is an almost constant symptom of facial and cranial erysipelas. The vestibular apparatus itself is not injured. This phenomenon may be of great importance in the differential diagnosis. VON RAD.

Vail: Cerebral Localization from the Standpoint of the Oculist. *Lancet-Clinic*, 1913, cx, 60. By Surg., Gynec. & Obst.

Ninety per cent of brain cases present definite eye symptoms, and these are of value in localization when studied in connection with other symptoms. Of the symptoms most often found, those considered are:

- (a) Conjugate paralysis and conjugate spasm of the muscles.
- (b) Pseudo-nystagmus and nystagmus.
- (c) Strabismus and disjunctive movements of the eyes.
- (d) The pupils.

(e) The fields of vision, ocular and mind blindness.

(f) Optic neuritis.

The author takes up each group and discusses its significance with special emphasis on brain tumor localization.

Guillemin, M.: A Contribution to the Pathogenesis and Treatment of Pharyngeal Collections of Otitic Origin (Contribution à la pathogénie et au traitement des collections pharyngiennes d'origine otique). *Thèse de Nancy*, 1913, July. By Journal de Chirurgie.

Retro- and lateropharyngeal abscesses following otitis are quite rare. They are generally considered very serious. In 19 cases collected by Collinet in 1895 there were 8 deaths.

Guillemin reports two very interesting cases of retro-pharyngeal abscess of otitic origin that were cured, and he attempts to show that, contrary to current opinion, this termination to otic suppuration is favorable.

The most interesting chapter of his work is that which deals with the pathogenesis. Guillemin does not speak of adeno-phlegmons. He studies only the abscesses of otitic origin that are accessible to view and exploration.

Otitic infection may spread to the retro-pharyngeal cellular tissue by three routes: 1. By way of the bones. The pus gains the sub-labyrinthine group of the mastoid cells and thus arrives at the extreme point of the temporal bone. It then reaches either the anterior lacerated foramen on the interior of the lateral aponeurosis of the pharynx or the ante-labyrinthine group which extends along the Eustachian tube. Also the pus may follow the groove in the mantle of the brain and reach the peritubal and peripharyngeal cellular tissue.

2. By the endocranial route. The pus collected secondarily upon one of the two endocranial sides of the temporal bone may spread from behind towards the anterior lacerated foramen, the occipital passage, or the anterior condylar passage, this being the common route in sinuso-digastric mastoiditis with suboccipital, subpetrous, and pharyngeal tracts.

3. By the exocranial route. The pus, after spontaneous trepanation of the cavity or of the antrum, gains the base of the skull where it follows the stylo-pharyngeal aponeurosis and thus reaches the lateral side of the pharynx.

On the basis of his theory that latero-pharyngeal abscess in the course of otic suppuration is a favorable symptom leading to rapid cure, Guillemin asks if it would not be permissible in cases of prolonged suppuration of the base of the brain to favor drainage of the suboccipital pus toward the pharynx. This may be accomplished by opening for it carefully a route following the condylar canal intermediate to the external side of the occipital condyl.

L. SENCERT.

SURGERY OF THE NOSE, THROAT, AND MOUTH

Keyle: The Nasal Septum and Its Relationship to the Syndrome of Sphenopalatine Ganglion Neurosis. *Interst. M. J.*, 1913, xx, 651.

By Surg., Gynec. & Obst.

With irritation of the complicated nervous mechanism of the attic of the nose the impressions are easily carried by way of the trifacial nerve to the nuclei of the facial and vagus nerves in the medulla. The result of irritation of the motor, sensory and sympathetic nerve fibers is far reaching, and nutritive or cardiovascular changes are to be expected. Some of the symptoms are: constriction, mental apathy, a feeling of fullness in the attic of the nose, sometimes nausea, and skin manifestations characteristic of a pronounced vasomotor disturbance. Asthenopia, migraine, or pain in the temple or eyeball may be experienced.

Submucous resection of a deflected septum is the first operative procedure, to be followed by operative treatment of the middle turbinated body or sinuses only if necessary.

The author also describes the sensory nerve supply of the nose and advocates local anæsthesia by the injection of 1 per cent cocaine solution along the course of these nerves.

EARLE B. FOWLER.

Klestadt: Surgery of the Nasal Sinuses (*Die Chirurgie der Nebenhöhlen der Nase*). *Ergebn. d. Chir. u. Orthop.*, 1913, vi, 138.

By Zentralbl. f. d. ges. Chir. u. i. Grenzgeb.

The monograph considers the literature of the last three years in reference to the progress made in the pathology and therapy of the diseases of the nasal sinuses. Onodis investigated the variations of the frontal sinus of 1200 skulls. In 5 per cent he found a bilateral absence, in 1 per cent a unilateral absence of this sinus. After a short discussion of foreign bodies and injuries of the sinuses he goes into detail in regard to the antra. Etiologically infectious diseases are important; the rhinogenous genesis, however, is the most frequent. Acute rhinitis is the most frequent source of infection. Diseases of the teeth also enter into consideration in maxillary sinus infections. Pathologically acute and chronic inflammations of the antra do not differ from other mucous membrane inflammations. For the diagnosis exploratory irrigations are of extreme importance and are discussed in detail. Exploratory puncture of the antrum from the alveolar process should be performed only in dental empyemas. In the other cases punctures should be made from the middle nasal cavity, being more easily performed in this way than from the inferior cavity. Irrigation of the frontal sinus is relatively easy by means of Killian's long speculum with which the middle tur-

binate can be lifted. All force is to be avoided on account of the danger of injuring the lamina cribrosa. Transillumination is applicable only to the antrum. Radiography has been extensively employed, especially in doubtful cases in children and in the unconscious. Clinically the inflammations of the antra have been divided into simple and complicated. Facial, oculo-orbital, and intracranial complications have been studied thoroughly in the last few years. Van der Hoeve's symptom, enlargement of the blind spot of the eye, is of importance in diseases of the posterior ethmoidal cells and of the sphenoidal sinus. This symptom, however, is not constant according to Markbreiter's investigations.

In regard to the treatment of inflammations of the antra the author emphasizes that radical extranasal operations should be performed only after unsuccessful purely conservative means and the lesser endonasal procedures. By these measures patients with antrum infections can almost certainly be cured, and the majority of those with frontal and sphenoidal sinus infections as well. In combinations of the two and in ethmoidal sinus suppurations the prognosis must be guarded. Excellent results are obtained with the radical operation of Caldwell-Luc in antrum suppurations. According to Bönnighaus almost 100 per cent of cures are obtained. The endonasal radical operation on the ethmoidal cells frequently cannot be performed in one session. Many times a cure is obtained only after several attempts. The extranasal operation is to be performed if the endonasal operation results in no improvement and in the presence of cerebral complications. The same applies to the radical operation on the sphenoidal sinus. The radical operation on the frontal sinus is best performed according to Killian's method. According to Bönnighaus's statistics (211 cases), a cure is obtained in 91 per cent of the operation. The mortality is 2 per cent. All sinus operations may be performed under local anæsthesia according to the method of Braunsch, although general anæsthesia is frequently necessary. In conclusion the author discusses other rare specific infections and other diseases of the sinuses of importance in the differential diagnosis, such as osteomyelitis, cysts of the superior maxilla, mucocèles, and blastomas.

KAHLER.

Mithoeffer. Alcohol Injections into the Superior Laryngeal Nerve in Tuberculous Laryngitis. *Ohio St. M. J.*, 1913, ix, 315.

By Surg., Gynec. & Obst.

Alcohol injections are a valuable adjunct in the palliative treatment of tuberculosis of the larynx, especially that form of the disease in which great

involvement of the superior orifice of the larynx exists—the aryteno-epiglottic type. The presence of a painful spot located at a point where the internal branch of the superior laryngeal nerve pierces the thyrohyoid membrane is a positive indication.

The technique is simple. The needle (one not too sharp) is inserted $1\frac{1}{2}$ cm. over the painful spot. The direction of the needle is then turned upward and outward toward the ear and fifteen to thirty drops of 80 per cent alcohol (warm) are injected.

EARLE B. FOWLER.

Masland: Antral Empyema, with the Presentation of an Efficient Conservative Operation for Its Cure. *N. Y. M. J.*, 1913, xcvi, 190.

By Surg., Gynec. & Obst.

In treatment of inflammation of the antrum after the formation of pus, it is necessary to establish good drainage and to afford an easy means of irrigation. This the author does by drilling through the nasal wall at the floor of the nose, using a straight drill, and inserting a permanent cannula about 4 cm. long. The irrigation may be carried out by the patient inserting the end of an all-rubber ear syringe into the mouth of the cannula. EARLE B. FOWLER.

Murphy: Use of Palate Mucous Membrane Flaps in Ankylosis of the Jaw Due to Cicatricial Formations in the Cheek. *J. Am. M. Ass.*, 1913, lxi, 245.

By Surg., Gynec. & Obst.

The author reports two cases in which this original method was successfully used. The flaps were of mucosa and pedicled, and obtained from the palate or floor of the mouth. On examination the first case showed complete immobility and no pain or tenderness on pressure over the joint. The roöntgenogram showed that there was no bony ankylosis. Through an external incision the jaw bones and articulation were exposed and a fibrous extra-articular ankylosis was demonstrated. What remained of the alveolar processes were removed and when the attachment of the temporal muscle was divided the jaw dropped.

A tongue-shaped pedicled flap was dissected from the palate, the base of the flap being toward the back of the mouth, the inner limb of the incision being about a quarter of an inch shorter than the outer. When this was reflected outward to cover the bone of the upper jaw, which was denuded by the chiseling, there was no contraction which might interfere with the circulation of the flap. The sides were sutured with very fine catgut to the margins of the gums and the tip was anchored to the cheek; a small pledget of antiseptic gauze was placed between the jaws. The

mucous membrane of the cheek was carefully approximated with fine catgut and the skin incision closed with horsehair. The wound was dusted with bismuth sub-iodid powder and plain sterile gauze applied. A wedge of folded gauze was placed between the teeth, which was within a week replaced by a wooden wedge, with which the patient spread the jaws. Four weeks after the operation she was able to open her mouth about an inch without assistance. Four months later the patient wrote that she could open her mouth about an inch and a half.

In the second case the cicatricial tissue was carefully divided and two tongue-shaped flaps interposed, one obtained from the floor of the mouth and the other from the palate. Both flaps were about two and one half inches in length and from one half to one inch in width. The result of the operation was entirely satisfactory. The patient left the hospital in five weeks and was able to open his mouth unassisted about an inch. H. A. POTTS.

Skilern, P. G., Jr.: Infiltration of the Lingual Nerve for Operations upon the Tongue and for the Relief of Pain in Inoperable Carcinoma. *Surg., Gynec. & Obst.*, 1913, xvii, 114.

By Surg., Gynec. & Obst.

Confronted with an ulcer of questionable malignancy in the anterior two thirds of the tongue, in which excision was indicated, it occurred to the author to induce anæsthesia by infiltration of the lingual nerve instead of by the more painful intra-lingual injections. The nerve was reached one half inch below and behind the third molar tooth, where it crosses a line projected between that tooth and the angle of the mandible. Submucous injection of 4 cc. of 2 per cent novocain and adrenalin, 1:3000, induced anæsthesia in the anterior two thirds of the tongue within five minutes. Neither the excision of the ulcer nor the Paquelin cautery were felt. A second patient had inoperable carcinoma with chronic pain. Injection at the same site of 1 cc. of 2 per cent novocain and adrenalin, 1:3000, in 4 cc. of 70 per cent alcohol induced analgesia in ten minutes. The following night the patient slept more soundly than he had slept for two months. In bilateral injections the tongue loses its power of determining temperature, so the patient should be warned to test the temperature of his food with his lips. Infiltration of the mandibular nerve is warranted only where growth or the absorption of the alveolar process after the shedding of the third molar tooth, has destroyed the landmarks of the lingual nerve.

Leiomyoma of the breast. L. STRONG. *Am. J. Obst.*, N. Y., 1913, lxxviii, 53.

Treatment of fractures of the clavicle. KÄFER. *München. med. Wchnschr.*, 1913, lx, No. 29.

Bilateral sterno-clavicular dislocation of congenital origin. GOURDON. *Rev. d'orthop.*, Par., 1913, iv, 304. [503]

Surgery of the sternum. H. HARTTUNG. *Deutsche Ztschr. f. Chir.*, 1913, cxxiii, 315.

A rare malformation of the thorax. P. KREISS. *München. med. Wchnschr.*, 1913, lx, 1435.

The development of the thorax from birth to the completion of its growth and its relation to rickets. ZELTNER. *Jahrb. f. Kinderh.*, 1913, lxxviii, No. 1.

Thoracotomy and hydrothorax. E. SCHEPELMANN. *Klin.-therap. Wchnschr.*, 1913, xx, 681. [503]

The indications for artificial pneumothorax in pulmonary tuberculosis. H. SCHUR and S. PLASCHKE. *Wien. klin. Wchnschr.*, 1913, xxvi, 961. [504]

On the possibility of achieving by partial pneumothorax the advantages of complete pneumothorax in the treatment of pulmonary tuberculosis. W. P. MORGAN. *Lancet*, Lond., 1913, clxxv, 18.

The frequency of the development of pleuro-pulmonary fistulae during artificial pneumothorax and the therapeutic indications which result therefrom. BARD. *Semaine méd.*, Par., 1913, xxxiii, No. 29.

Technique of artificial pneumothorax. KAUFMANN. *Internat. Zentralbl. f. d. ges. Tuberkul. Forsch.*, 1913, vii, 320. [504]

Efforts toward the cure of pulmonary tuberculosis by surgical intervention. ALVAREZ. *Rev. de med. y cir. pract.*, Madrid, 1913, xxxvii, No. 1272.

Rational pneumopexy in thoracic surgery. G. LERDA. *Deutsche Ztschr. f. Chir.*, 1913, cxxiii, 405.

Aspiration after thoracotomy in purulent pleurisy. DELBET. *J. d. praticiens*, Par., 1913, xxvii, No. 29.

Pneumolysis. JESSEN. *München. med. Wchnschr.*, 1913, lx, No. 29.

Extrapleural pneumolysis with immediate plugging (Plombierung) in pulmonary tuberculosis. G. BAER. *München. med. Wchnschr.*, 1913, lx, 1587.

Two cases of traumatic hemothorax. LEURET and GAUVENET. *Lyon méd.*, 1913, cxi, No. 27.

Final result of an intrathoracic subpleural graft in a case of an intrapulmonary suppurative cavity on the right side. T. TUFFIER. *Bull. et mem. Soc. de chir. de Par.*, 1913, xxxix, 740. [505]

The transpleural path of access. LAPEYRE. *Arch. gén. de chir.*, Par., 1913, vii, No. 6.

Primary lympho-endothelioma of the pleura. TRAINA. *Rev. méd. de Chile*, 1913, xli, No. 2.

A case of tumor of the mediastinum. LUCCARELLI. *Clin. chir.*, 1913, xxi, No. 6.

The thymus. BASCH. *Deutsche med. Wchnschr.*, 1913, xxxix, No. 30.

Death caused by persistent thymus in small children. PEREZ-MONTAUT. *Frankf. Ztschr. f. Path.*, Wiesb., 1913, xiii, No. 2.

The chemical composition of the infantile thymus. L. MENDELSON. *Arch. f. Kinderh.*, 1913, lx, Festschr. f. Adolf Baginsky, 491.

Is it possible to obtain a successful demonstration of a persistent or hyperplastic thymus by means of Abderhalden's ferment reaction? KOLB. *München. med. Wchnschr.*, 1913, lx, No. 30.

New growth of the thymus in an adult associated with syndrome of transverse myelitis caused by vertebral metastases. ROCAVILLA. *Gazz. d. osp. e d. Clin.*, Milano, 1913, xxxiv, No. 87.

Trachea and Lungs

Wax-paraffin casts of the trachea, taken from the organs in situ. OPIKOFER. *Arch. f. Laryngol. u. Rhinol.*, 1913, xxvii, No. 3.

Artificial breathing continued successfully for 15 days. S. F. DERJUSHINSKY. *Verhandl. d. XII Kong. Russ. Chir.*, 1913, xii, 208. [505]

"Cylindromata" of the upper respiratory passages. PFEIFFER. *Arch. f. Laryngol. u. Rhinol.*, 1913, xxvii, No. 3.

Diagnosis and treatment of lodgment of foreign bodies in the respiratory passages. GUISEZ. *Ann. d. mal. de l'oreille, du larynx, du nez et du pharynx*, Par., 1913, xxxix, No. 6.

A voluminous foreign body in the respiratory passages; extraction by tracheotomy; recovery. CANTILENA and STRETTI. *Policlin.*, Roma, 1913, xx, No. 7.

Diagnosis of tracheo-bronchial foreign bodies. GUISEZ. *J. d. praticiens*, Par., 1913, xxvii, No. 27.

Foreign bodies in trachea and bronchial tubes. F. G. HODGSON. *J.-Rec. Med.*, 1913, lx, 146.

The extraction of a foreign body from the bronchi. SAVIN. *Monatschr. f. Ohrenh. u. Laryngo-Rhinol.*, 1913, 776.

Two cases of death in bronchoscopic extraction of foreign bodies. V. HINSBERG. *Ztschr. f. Ohrenh. u. f. d. Krankh. d. Luftw.*, 1913, lxxviii, 180.

Foreign body in right bronchus; lower bronchoscopy; successful extraction. G. HUTCHINSON. *Med. Rec.*, 1913, lxxxiv, 1.

A needle in the left bronchus of a girl 17 months old. GAREL and GIGNOUX. *Ann. d. mal. de l'oreille, du larynx, du nez et du pharynx*, Par., 1913, xxxix, No. 6.

Extraction of foreign bodies from the lung in children. SEHRT. *München. med. Wchnschr.*, 1913, lx, No. 27.

Spontaneous healing of traumata of the lung. TIEGEL. *Arch. f. klin. Chir.*, 1913, ci, No. 4.

A case of cancer of the lung. ORLOW. *Terap. Obozrenié*, Odessa, 1913, v, No. 12.

Metaplasia of the connective tissue of the lung during primary epithelioma. ARGAUD, CRESPIN and LEGROUX. *Province méd.*, Par., 1913, xxvi, No. 28.

Invasion of the lungs by tuberculosis, as seen by the röntgenologist. G. H. STOVER. *Denver M. Times*, 1913, xxxiii, 1.

Pulmonary echinococci and critical notes on the diagnosis of thoracic echinococci. E. KRÜGER. Dissertation, Königsberg, 1913.

Pulmonary embolism as a cause of post-operative death. G. PETRÉN. Beitr. z. klin. Chir., 1913, lxxxiv, 606. [505]

Arborization of ossification in the lung. K. RIEDIGER. Dissertation, Erlangen, 1913.

Heart and Vascular System

Wounds of the heart. LEOTTA. Policlin., Roma, 1913, xx, No. 7.

Two cases of sutured wounds of the heart; one death; one recovery. CERNÉ. Bull. méd., Par., 1913, xxvii, No. 55.

Wounds of the pericardium and heart. G. C. HOLLADAY. N. Y. M. J., 1913, xcvi, 186.

Pericardiolysis in certain affections of the heart or pre-pericardiac thoracotomy. DELAGENIERE. Arch. prov. de chir., Par., 1913, xxii, No. 6.

The treatment of tubercular pericarditis by pericardotomy without drainage. O. JACOB. Bull. et mem. Soc. de chir. de Par., 1913, xxxix, 732. [505]

Should we operate on the pericardium? BLECHMANN. Paris méd., 1913, No. 33.

Aortic aneurism rupturing into the pulmonary artery, with a report of three cases. H. N. STEVENSON. Bull. Johns Hopkins Hosp., 1913, xxiv, 217.

The pathology of syphilitic aortitis with a contribution to the formation of aneurisms. M. C. WINTERNITZ. Bull. Johns Hopkins Hosp., 1913, xxiv, 212.

Pharynx and Oesophagus

The value of the methods of extracting foreign bodies from the oesophagus. WAGNER. Deutsche med. Wchnschr., 1913, xxix, No. 28.

Oesophagoscopy, laryngoscopy, and bronchoscopy as an aid to the detection of disease and removal of foreign bodies impacted in the food and air passages. W. MILLIGAN. Lancet, Lond., 1913, clxxxv, 65.

Notes on recent cases of oesophagoscopy, bronchoscopy, and laryngoscopy. R. H. JOHNSTON. Am. J. Surg., 1913, xvii, 259.

The removal of foreign bodies from the upper end of the oesophagus. R. H. JOHNSTON. Laryngoscope, 1913, xxiii, 761.

Diagnosis and treatment of cicatricial stenosis of the oesophagus. GUISEZ. Arch. internat. de laryngol., d'otol. et de rhinol., Par., 1913, xxxv, No. 3.

A diverticulum formed just above a cicatricial stenosis of the oesophagus. H. FLESC. Jahrb. f. Kinderh., 1913, lxxviii, 83.

A case of very marked stenosis of the oesophagus leading to complete occlusion in the lower portion following cauterization of the lung. K. MAISEL. Dissertation, Erlangen, 1913.

Congenital stenoses of the oesophagus. GUISEZ. Rev. med., 1913, xxi, 262. [506]

Types of occlusion of the oesophagus in early life. T. M. ROTCH. Am. J. Dis. Children, 1913, vi, 1. [506]

Congenital occlusions of the oesophagus and lesser bowel. G. H. EDINGTON. Glasgow M. J., 1913, lxxx, 16.

The present status of oesophagoscopy in cancer of the oesophagus. R. LEWINSOHN. Med. Rec., 1913, lxxxiv, 65.

The radical operation in carcinoma of the oesophagus. DENK. Zentralbl. f. Chir., 1913, xl, No. 27.

Report on the first successful resection of the thoracic portion of oesophagus for carcinoma. TOREK. Deutsche Ztschr. f. Chir., 1913, cxiii, Nos. 3-4.

A case of oesophagitis dessecans following poisoning by acetic acid. GESSELEWITSCH. Russk. Vrach, 1913, xii, 771. [506]

Plastic surgery of the oesophagus. I. O. GALPERN. Verhandl. d. XII Kong. Russ. Chir., Moscow, 1913, xii, 113.

Plastic surgery of the oesophagus. ENDERLEN and HOTZ. Zentralbl. f. Chir., 1913, xl, 1175.

Miscellaneous

Infection of the thoracic cavity. BURCKHARDT. Arch. f. klin. Chir., 1913, ci, No. 4.

Penetrating thoraco-abdominal wounds. GULEKE. Arch. f. klin. Chir., 1913, ci, No. 4.

The rapidity with which contamination of the thoracic cavity and its contained glands follows infection of the peritoneal cavity. C. C. TWORT. Lancet, Lond., 1913, ii, 216.

SURGERY OF THE ABDOMEN

Abdominal Wall and Peritoneum

A case of ossification of the scar of a laparotomy wound. BORGH. Morgagni, 1913, lv, No. 6.

Penetrating wounds of the abdomen. IRAOLA. Rev. de l. hosp., Montevideo, 1913, lv, No. 4.

Five cases of contusion of the abdomen. PRAT. Rev. de l. hosp., Montevideo, 1913, lv, No. 5.

Surgical treatment of subcutaneous lesions of the abdomen. GLASSTEIN. Terap. Obozréníé, Odessa, 1913, v, No. 12.

Desmoid tumor of rectus muscle. J. B. MURPHY. Surg. Clin. J. B. Murphy, 1913, ii, No. 3. [506]

Report of an autopsy on a case in which both of the rectus muscles were cut transversely. S. R. MAXEINER. J.-Lancet, 1913, xxxiii, 376.

Laparoscopy and thoracoscopy. JACOBÆUS. J. méd. franc., Par., 1913, vii, No. 7.

The value of the introduction of oxygen or air into the abdominal cavity for purposes of experimental and diag-

nostic röntgenology. WEBER. Fortschr. a. d. Geb. d. Röntgenstr., Hamburg, 1913, xx, No. 5.

Air in the abdomen following laparotomies. COHN. Berl. klin. Wchnschr., 1913, l, No. 29.

Retroperitoneal sarcoma with recovery; a case report. TAFT and JARVIS. Am. J. Surg., 1913, xxvii, 271.

Retroperitoneal cysts of Wolffian origin; Wolffian cyst of the descending mesocolon. JACQUOT and FAIRISE. Rev. de gynéc. et de chir. abdom., Par., 1913, xx, No. 6.

Normal peritoneal fold. EVANS and BOWEN. Iowa M. J., 1913, xx, 1.

Multiple hydatid cysts of the peritoneum. DÉVÉ. Arch. gén. de chir., Par., 1913, vii, No. 6.

Biliary peritonitis. VOGEL. Wien. klin. Wchnschr., 1913, xxvi, No. 28.

Rehn's treatment of peritonitis. K. PROPPING. Deutsche med. Wchnschr., 1913, xxxix, 1096. [507]

Camphorated oil in peritonitis and abscesses of the pouch of Douglas. BLECHER. München. med. Wchnschr., 1913, lx, 1261. [507]

Tubercular peritonitis. F. HÄRTEL. *Ergebn. d. Chir. u. Orthop.*, 1913, vi, 370. [507]

The employment of tincture of iodine in dry peritoneal tuberculosis. S. STOCKER. *Schweiz. Rundschau f. Med.*, 1913, xiii, 745. [507]

The operative treatment of peritoneal and genital tuberculosis. O. SCHMIDT. *Ztschr. f. Geburtsh. u. Gynäk.*, 1913, lxxiii, 404.

Tubercular peritonitis and its operative treatment. A. G. RUSSANOFF. Dissertation, Moscow, 1913. [507]

Subphrenic abscess caused by an ulcer. L. HÖFLICH and Z. TAKÁCS. *Budapesti kir. Orvose. értesítője*, 1913, ii, 376.

Diaphragmatic eventration (relaxation of the diaphragm). P. KRAUSE. *Deutsche Ztschr. f. Nervenhe.*, Leipzig, 1913, xlvii, Festschr. f. von Strümpell, 328.

Diaphragmatic hernia in a phthisical subject. MELCHIOR. *Ugesk. f. Læger, Kjøbenh.*, 1913, lxxv, No. 25.

Accidents and complications of hernia. A. A. KERR. *Am. J. Surg.*, 1913, xxvii, 245.

Inguinal hernia of fatty tissues; intermittent crural properitoneal hernia. VANVERTS. *Echo méd. du nord*, Lille, 1913, xvii, No. 27.

Constricted hernia of the epiploön. JABOULAY. *Progrès méd.*, Par., 1913, xlv, No. 26.

Multiple herniæ, obturator, ischiatic and femoral, in an adult. H. RISCHBIETH. *Australas. M. Gaz.*, 1913, xxxiv, 71.

Two very voluminous scrotal hernias. GIERSEWSKI. *Deutsche med. Wchnschr.*, 1913, xxxix, 1207.

Hernia-urethral stricture; report of two cases. J. M. WHITE. *Internat. J. Surg.*, 1913, xxvi, 251.

Retrograde incarceration—hernia "en W." LOUIS FRIEDMAN. *Surg., Gynec. & Obst.*, 1913, xvii, 97. [508]

A new case of hernia subtransversalis. G. PEUS. *Gynäk. Rundschau*, 1913, vii, 281. [508]

A simple aid in the reduction of hernias in nurslings. A. NUSZBAUM. *München. med. Wchnschr.*, 1913, lx, 1434.

Prophylaxis against hernias and protrusions following laparotomies. G. A. WALJASCHKO and A. A. LEBEDEV. *Arch. f. klin. Chir.*, 1913, ci, 896.

The appendix and appendicitis in the herniary sac and appendectomy in radical operations for inguinal and crural hernia. J. NORRLIN. *Hygiea*, Stockholm, 1913, lxxv, 379.

Permanent operative results of crural hernias. H. ROSENFELD. *Beitr. z. klin. Chir.*, 1913, lxxxiv, 563.

A rational deep suture for Bassini's operation. A. SANATUCCI. *Clin. chir.*, 1913, xxi, 779. [509]

A case of intra-herniary torsion of the great omentum. PATEL and SANTY. *Lyon chir.*, 1913, x, No. 1.

The significance of the omentum in physiological and pathological conditions. W. GUNDERMANN. *Beitr. z. klin. Chir.*, 1913, lxxxiv, 587. [509]

The pathology of the great omentum. GUNDERMANN. *Zentralbl. f. Chir.*, 1913, xl, 1180.

Circumscribed inflammatory tumor formation in the pelvis, originating from the greater omentum. SCHMIEDEN. *Berl. klin. Wchnschr.*, 1913, l, 908. [509]

An uncommon case of lymphosarcoma of the mesenteric glands. COEN. *Riv. osp.*, Roma, 1913, iii, No. 13.

An interesting case of tumor of the mesentery. CABRERA and DOMINGUEZ. *Rev. de med. y cir. de la Habana*, 1913, xviii, No. 13.

Mesenteric cysts, with report of a case of sanguineous cysts of the mesentery of the small intestine. C. H. FRAZIER. *J. Am. M. Ass.*, 1913, lxi, 97. [509]

Mesenteric and retroperitoneal blood cysts. F. CAROTOLRI. *Clin. chir.*, 1913, xxi, 725. [510]

A case of mesenteric thrombosis. H. H. RAYNER. *Med. Chronicle*, 1913, lvii, 130.

Gastro-Intestinal Tract

Radiography in a case of hairball in the stomach. C. T. HOLLAND. *Arch. Röntg. Ray*, 1913, xvii, 46.

Some radiographs of obscure stomach and intestinal cases. S. TOUSEY. *N. Y. M. J.*, 1913, xcvii, 1.

X-ray examination of a woman in whom the stomach and two vagus nerves had been resected. M. COHN. *Berl. klin. Wchnschr.*, 1913, l, 1393.

The effect of meals taken subsequent to the test-meal in röntgenological determination of the motility of the stomach. M. LÜDIN. *Deutsche med. Wchnschr.*, 1913, xxix, 1239.

Movements of the stomach and duodenum studied by the perfusion method. P. CARNOT. *Compt. rend. Soc. de Biol.*, 1913, lxxiv, 1265. [510]

Covered perforations of the stomach. HUSTIN. *J. méd. de Brux.*, 1913, xviii, No. 27.

Diagnosis and surgical treatment of gastric and duodenal ulcers. SHERREN. *Berl. klin. Wchnschr.*, 1913, l, No. 28.

The X-ray method in diagnosis of gastric and duodenal ulcer. F. W. WHITE and A. W. GEORGE. *Boston M. & S. J.*, 1913, clxix, 157. [511]

The X-ray in the diagnosis of gastric ulcer and its sequelæ. R. W. MILLS and R. D. CARMAN. *Surg., Gynec. & Obst.*, 1913, xvii, 1. [511]

X-ray diagnosis of ulcers of the stomach. DOMINGUEZ. *Rev. de med. y cir. de la Habana*, 1913, xviii, No. 12.

Chronic gastric ulcer in the X-ray picture of the air-inflated stomach. W. RÖPKE. *Mitt. a. d. Grenzgeb. d. Med. u. Chir.*, 1913, xxvi, 307. [512]

Attempted X-ray treatment of ulcer of the stomach. KODON. *Fortschr. a. d. Geb. d. Röntgenstr.*, Hamburg, 1913, xx, No. 3.

Heredity of round ulcer of the stomach. DAUWE. *Arch. d. mal. de l'appareil digest. et nutr.*, Par., 1913, vii, No. 7.

Large ulcer of the stomach in a tuberculous patient. MATTEI and RABOUL LACHAUX. *Marseille méd.*, 1913, l, No. 14.

A preliminary note on the experimental production of gastric ulcers by the intravenous injection of clumped colon bacilli. E. C. STEINHARTER. *Boston M. & S. J.*, 1913, clxix, 81. [512]

Perforation of an ulcer of the stomach under ordinary strain not a basis for a claim for indemnity. FRANK. *Med. Klin.*, Berl., 1913, ix, No. 27.

Posterior gastrojejunostomy in acute perforative ulcer of the stomach and duodenum. J. B. DEEVER. *J. Am. M. Ass.*, 1913, lxi, 75. [512]

The relations of chronic gastritis and its sequelæ and of chronic gastric ulcer to the development of gastric carcinoma. G. E. KONJETZNY. *Beitr. z. klin. Chir.*, 1913, lxxxv, 455.

Carcinoma of the stomach. C. GRAHAM. *Med. Herald*, 1913, xxxii, 7.

Cancer of the stomach. TRUESDALE. *Boston M. & S. J.*, 1913, clxix, 44. [513]

The early diagnosis of gastric carcinoma by aid of Röntgen ray. W. F. HILGER. *Wis. M. J.*, 1913, xii, 46.

Negative röntgenological diagnosis in clinically diagnosed gastric carcinoma. G. H. STOVE. *Med. Rec.*, 1913, lxxxiv, 66.

The peptide-splitting ferment of the carcinomatous stomach and its value in diagnosis. A. G. BRYCE. *Med. Chron.*, Balt., 1913, xxv, 161.

Perforation in cancer of the stomach. JAISON. *Arch. d. mal. de l'appareil digest. et nutr.*, Par., 1913, vii, No. 7.

Neoplasm of the stomach and of the pancreas. MATTEI and REBOUL-LACHAUX. *Marseille méd.*, 1913, l, No. 14.

Fibromatosis of the stomach and its relationship to ulcer. A. THOMSON and J. M. GRAHAM. *Edinb. M. J.*, 1913, xi, 7. [513]

A voluminous leiomyoma of the gastric wall. G. MOCCIA. *Clin. chir.*, 1913, xxi, 1331.

Gastro-colic resection, a typical operation in certain forms of gastric carcinoma. G. PERTHES. *Zentralbl. f. Chir.*, 1913, xl, 1097.

Extensive resection of the stomach. MARIO. *Clin. chir.*, Milano, 1913, xxi, No. 6.

The relation of gastrostomy to inoperable carcinoma of the oesophagus, with a description of a new method of performing gastrostomy. H. H. JANEWAY. *J. Am. M. Ass.*, 1913, lxi, 93. [514]

The technique of the suture in gastrostomy after the method of Witzel. M. M. KRJUKOW. *Arch. f. klin. Chir.*, 1913, ci, 843.

A procedure of gastric autoplasmic surgery by means of transplantation of a loop of the small intestine; presentation of a specimen from experiments performed on a dog. CHASTENET DE GÉRY. *Gaz. méd. de Nantes*, 1913, xxxi, No. 28.

The use of the rubber dam in gastro- and entero-enterostomy. C. E. RUTH. *Med. Council*, 1913, xviii, 249.

Stenosis of the pylorus in infancy. C. L. SCUDDER. *Illinois M. J.*, 1913, xxiv, 1.

Congenital hypertrophic pyloric stenosis. R. E. McKECHNIE. *Canad. M. Ass. J.*, 1913, iii, 566.

Pyloropexy. A. HOFMANN. *Zentralbl. f. Chir.*, 1913, xl, 1169.

How is exclusion of the pylorus and the duodenum to be obtained? LERICHE. *Lyon chir.*, 1913, x, No. 1.

Indications for the duodenal method of alimentation. EINBORN. *Deutsche med. Wchnschr.*, 1913, xxxix, No. 29.

Permanent alimentation through a duodenal sound. LAZARUS. *Berl. klin. Wchnschr.*, 1913, l, No. 30.

Contusions of the duodenum. FAVREUL. *Arch. prov. de chir.*, Par., 1913, xxii, No. 6.

The positive diagnosis of duodenal ulcer by means of the Röntgen ray. A. W. GEORGE. *Am. Quart. Röntgenol.*, 1913, iv, 187. [514]

The diagnosis and prognosis of duodenal ulcer. J. T. PILCHER. *Med. Rec.*, 1913, lxxxiv, 156.

My duodenal ulcer. X. COMBES. *Med. Press & Circ.*, 1913, xcvi, 58.

X-ray diagnosis of stenoses of the small intestine. H. ASSMANN. *Deutsche Ztschr. f. Nervenhe.*, 1913, xlvii, Festschr. f. von Strümpell, 1.

Traumatic cicatricial stenosis of the intestines while the abdominal walls are intact. P. F. KOLTSCHIN. *Chirurgia*, St. Petersburg., 1913, xxxiii, 672.

Intestinal obstruction. W. E. DICKEN. *J. Okla. St. M. Ass.*, 1913, vi, 68.

Intestinal obstruction due to large gall-stone in ileum. J. B. MURPHY. *Surg. Clin. J. B. Murphy*, 1913, ii, No. 3.

Intestinal obstruction in the rabbit. BUNTING and JONES. *J. Exp. Med.*, 1913, xxviii, 25. [514]

Obstruction of small intestine due to adhesion of stomach to peritoneum in lesser peritoneal cavity; division of adhesion; cure; case report. S. C. NASON. *Am. J. Surg.*, 1913, xxvii, 272.

A rare case of intestinal occlusion. KIRCHENBERGER. *Wien. med. Wchnschr.*, 1913, lxiii, No. 29.

A case of ileus caused by retroversion of the large intestine. T. ROVSING. *Hosp.-Tid, Kjøbenhavn.*, 1913, lvi, 853.

Congenital obliteration of the small intestine. H. VON THUN. *Hosp.-Tid, Kjøbenhavn.*, 1913, lvi, 827.

Incarceration of the intestine. A. P. SEMENOWSKI. *Chirurgia*, St. Petersburg., 1913, xxxiii, 681.

Acute and chronic invaginations. S. B. DE GROOT. *Geneesk. Bladen u. klin. en labor*, 1913, xiii, 1.

Ascarides as the cause of intestinal invagination. HOHMEIER. *Zentralbl. f. Chir.*, 1913, xl, 1178.

Surgical affections caused by ascarides. SCHLOESSMANN. *Zentralbl. f. Chir.*, 1913, xl, 1178.

Volvulus as a cause of melæna neonatorum. L. NÜRNBERGER. *Samml. klin. Vortr.*, 1913, No. 679, 639.

Aseptic enterostomy. A. WOLFF. *Zentralbl. f. Chir.*, 1913, xl, 1170.

Note on a case of incarceration of the cæcum and ascending colon in lesser sac of peritoneum; operation; recovery. I. BACK. *Lancet*, Lond., 1913, clxxxv, 17.

Infectious granuloma of caput coli; resection of cæcum and anastomosis of ileum to ascending colon. J. B. MURPHY. *Surg. Clin. J. B. Murphy*, 1913, ii, No. 3.

Resection of the ileo-cæcal portion of the intestine on account of invagination caused by a submucous lipoma. ANDRÉE. *Beitr. z. klin. Chir.*, 1913, lxxxv, No. 1.

The black (pigmented) appendix. W. BATTLE. *Lancet*, Lond., 1913, clxxxv, 135.

The pathology and diagnosis of appendicitis. F. H. SMITH. *Va. M. Semi-Month.*, 1913, xviii, 188.

Is appendicitis ever catarrhal? F. A. PALMER. *Med. Rec.*, 1913, lxxxiv, 139.

Symptoms and medical treatment of appendicitis. A. B. GRUBB. *Va. M. Semi-Month.*, 1913, xviii, 194.

Diagnosis of paresis of the appendix. STERN. *Deutsche med. Wchnschr.*, 1913, xxxix, No. 27.

Errors of diagnosis in appendicitis. DE QUERVAIN. *Rev. méd. Suisse romande*, 1913, xxxiii, 513. [515]

Diagnosis of appendicitis. DIVARIS. *Grèce med.*, Athenai, 1913, xv, Nos. 11 and 12.

Appendicitis in children. J. G. SHERRILL. *Pediatrics*, 1913, xxv, 433.

Two cases simulating appendicitis. E. S. JACKSON. *Australas. M. Gaz.*, 1913, xxxiv, 4.

Ileus and appendicitis. W. WIEGELS. *München. med. Wchnschr.*, 1913, lx, 1644.

Hydro-appendicitis. DUCOUX. *Rev. de gynec. et de chir. abdom.*, 1913, xx, 143. [515]

Cases of appendicitis, cholelithiasis and pericholecystitis showing the clinical picture of ulcer of the stomach or duodenum. J. PÖLYA. *Budapesti Kir. Orvose. értesítője*, 1913, ii, 377. [515]

The co-relation of appendicitis, mucous colitis and membranous pericolicitis. A. BENJAMIN. *J.-Lancet*, 1913, xxxii, 401.

A case of formation of pseudo-myxoma following appendicitis. PACZEK. *Wien. klin. Rundschau*, 1913, xxvii, Nos. 27 and 28.

Pseudo-myxoma of the appendix. COCHEZ. *Bull. méd. de l'Algérie*, Alger, 1913, xxiv, No. 11.

Gelatinous cysts of the appendix. MÉRÉL and DAUNIC. *Toulouse méd.*, 1913, xv, No. 13.

Congenital absence of the appendix and acute appendicular syndrome. BÉRARD and BUCHE. *Province méd.*, Par., 1913, xxvi, No. 26.

Gastric hyperacidity of appendicular origin. S. SOLIERI. *Rev. osp.*, 1913, iii, No. 10. [515]

Liver, Pancreas and Spleen

The relations of the liver to the thyro-parathyroid apparatus. DELAUNAY. J. sc. et méd. et Poitiers, 1913, v, No. 7.

Tests for hepatic function and disease under experimental conditions. WHIPPLE, MASON and PEIGHTAL. Bull. Johns Hopkins Hosp., 1913, xxiv, 207.

Radioscopic examination of the liver. JAUZEAS. Arch. Röntg. Ray, 1913, xviii, 48. [518]

Transjejunal drainage of the liver. NORDMANN. Arch. f. klin. Chir., 1913, ci, No. 4.

Subcutaneous injuries of the liver. F. A. FÁYKISS. Budapesti Orvosi Ujság, 1913, xi, 53.

Cicatrization of wounds of the liver, the gall-bladder and the kidney. VALIACHKO and LEBEDEFF. Russk. Vrach, St. Petersburg, 1913, xii, No. 28.

Primary chorio-epithelioma of the liver. B. FISCHER. Frankf. Ztschr. f. Pathol., 1913, xii, 462. [518]

Hepatic hydropneumocyst which developed in a large abscess of the liver, following dysentery; radioscopic and radiographic examinations. CLUZET and BAUR. Lyon méd., 1913, cxxi, No. 28.

Some clinical considerations on the diagnosis and treatment of abscess of the liver, based on 200 personal cases. SIERRA. Rev. méd. de Chile, 1913, xli, No. 3.

Abscesses of the liver at the hospital of Haiphong. SAMBUC. Arch. gén. de chir., Par., 1913, vii, No. 6.

Large amoebic abscess of the liver; rapid cure by surgical treatment followed by emetine. A. CHAUFFARD. Bull. et mem. Soc. med. d. hôp. de Par., 1913, No. 10, 630. [518]

Nine cases of dysentery and amoebic abscess of the liver cured by Rogers' method. MOROTTA. Argentina med., Buenos Aires, 1913, ii, No. 27.

Radical operation in alveolar echinococcus of the liver. Comment on the article of the same title by Prof. Mysch. N. ALFUTOFF. Chir. arch. Veliaminova, St. Petersburg, 1913, xxix, 519.

The employment of fascia lata in resections of the liver. CHESSIN. Zentralbl. f. Chir., 1913, xl, No. 30.

Resection of the liver. LINDNER. Zentralbl. f. Chir., 1913, xl, 917.

Resection of the left lobe of the liver because of cavernoma. Z. COLLEONI. Gazz. d. osp. e d. clin., Milano, 1913, xxvix, No. 78.

The gall-bladder and the chemistry of the stomach. MAGNUS. Med. Klin., Berl., 1913, ix, No. 27.

Congenital anomalies of the gall-bladder and the hepatic artery. KEHR. Zentralbl. f. Chir., 1913, xl, 690. [519]

The incidence of stone in Egypt, with remarks on a series of 312 operations. F. C. MADDEN. Lancet, Lond., 1913, clxxxv, 132.

Statistical, clinical and chemical studies on the etiology of gall-stones with special reference to Japanese and German conditions. H. MIYAKE. Arch. f. klin. Chir., 1913, ci, 54. [519]

Gall-stones; a plea for earlier operation. D'ARCY POWER. Brit. J. Surg., 1913, i, 21.

A case of gall-stones with chronic pancreatitis. H. T. MURSELL. South African M. Rec., 1913, xi, 259.

Medical treatment of gall-stones. T. W. GRAYSON. Pittsburgh M. J., 1913, i, 25.

Injury of the gall-bladder by a bullet. G. VIGYÁZÓ. Budapesti Kir. Orvose. értesítője, 1913, xi, 387.

The conditions of acidity of the stomach in affections of the gall-bladder and their value in therapeutics. OHLY. Deutsche med. Wchnschr., 1913, xxxix, No. 29.

Cholecystitis and some of its sequelæ. A. F. SAMPSON. Tex. M. J., 1913, xxix, 1.

Congenital defect of the bile ducts. F. SCHOTTEN. Mitt. a. d. Ham. Staatskrankenanst., 1913, xiv, 1.

Affections of the bile-ducts. PRINGSHEIM. Med. Klin., Berl., 1913, ix, Nos. 29 and 30.

Angiocholitis and biliary lithiasis. DELREZ. Scalpel et Liège méd., 1913, lxv, No. 52.

A case of perforated common bile duct followed by subphrenic abscess, operation and recovery. C. CAMPBELL-HORSFALL. Brit. M. J., 1913, ii, 118.

Cysts of the ductus choledochus. W. M. MINTZ. Verhandl. d. XII. Kong. Russ. Chir., Moscow, 1913, xii, 161.

Operative treatment of chronic occlusion of the choledochus. E. J. KRAMARENKO. Verhandl. d. XII. Kong. Russ. Chir., Moscow, 1913, xii, 157.

Cholecystenterostomy for obstruction of the common bile duct due to multiple hydatid disease. G. H. ABBOTT. Australas. M. Gaz., 1913, xxxiv, 76.

Acute pancreatic syndrome. SFORZA. Riv. osp., Roma, 1913, iii, No. 13.

Clinical and experimental contributions on necrosis of the pancreas. SEIDEL. Beitr. z. klin. Chir., 1913, lxxxv, No. 1.

Three cases of acute affections of the pancreas associated with multiple necroses of the subperitoneal adipose tissue. KOSLOWSKY. Russk. Vrach, St. Petersburg, 1913, xii, 768.

Adenoma of the pancreas. PROSOROWSKY. Frankf. Ztschr. f. Path., Wiesb., 1913, xiii, No. 2.

Traumatic pancreatic pseudo-cyst. MOORHEAD and STONY. Clin. J., 1913, xlii, 209.

Cyst of the pancreas. S. B. MARKS. Ky. M. J., 1913, xi, 551.

Diagnosis and treatment of acute affections of the pancreas. W. VON REYHER. St. Petersburg. med. Ztschr., 1913, xxxviii, 128.

New technique for establishing a permanent pancreatic fistula; presentation of animals and specimens. A. FROUIN. Compt. rend. hebdom. Soc. de Biol., 1913, lxxiv, 1283. [519]

Recent studies on surgery of the pancreas. SEHRT. Med. Klin., Berl., 1913, ix, No. 26.

Lecture on enlargement of the spleen. F. TAYLOR. Clin. J., 1913, xlii, 247.

A case of subcutaneous rupture of the spleen; splenectomy; recovery. MICKHAIOFF. J. d. praticiens, Par., 1913, xxvii, No. 28.

Two cases of primary sarcoma of the spleen. PRINZING. Frankf. Ztschr. f. Path., Wiesb., 1913, xiii, No. 2.

Affections caused by echinococcus; echinococcus of the spleen. W. SCHIPATSCHEFF. Chirurgia, St. Petersburg, 1913, xxxiii, 770.

Banti's disease. GRUTZNER. Beitr. z. klin. Chir., 1913, lxxxv, No. 1.

The operative treatment of Banti's disease. TILLMANN. Zentralbl. f. Chir., 1913, xl, 917.

Paludal spleen in pelvic ectopy; splenectomy. CURTILLET, LOMBARD and PÉLISSIER. Bull. méd. de l'Algérie, Alger, 1913, xxiv, No. 11.

Miscellaneous

The diagnosis of abdominal tumors. SCOBLEW. Frankf. Ztschr. f. Path., Wiesb., 1913, xiii, No. 2.

Gunshot wound of the abdomen, followed by septic venous thrombosis of the femoral vein; operation; recovery. W. GRIESS. Lancet-Clin., 1913, cx, 34.

Some acute abdominal perils. J. W. LEECH. Clin. J., 1913, xlii, 231.

The necessity for accurate pre-operative diagnosis and

the methods to be employed in intra-abdominal lesions. H. E. HAYD. Buffalo M. J., 1913, lxviii, 12.

Comparative studies on the value of unpedunculated flaps of omentum, peritoneum and mesentery for the re-enforcement of sutures. SASAKI. Deutsche Ztschr. f. Chir., 1913, cxxiii, Nos. 1 and 2.

Some surgical diseases of the abdomen in children.

BARRETT. Practitioner, Lond., 1913, xci, 65.

Complications and sequelæ of abdominal surgery.

F. F. LAWRENCE. Ohio St. M. J., 1913, ix, 138.

Interesting cases of abdominal surgery. M. HERCZEL. Budapesti Orvosi Ujsäg, Sebénét, 1913, xi, 13.

SURGERY OF THE EXTREMITIES

Diseases of Bones, Joints, Muscles, Tendons— General Conditions Commonly Found in the Extremities

Negative pressure in the long hollow bones of the dog. A critical and experimental contribution on the article of the same title by Ernst O. P. Schultze and B. J. Behau. M. ROTHMANN. München. med. Wchnschr., 1913, lx, 1664.

Anatomical findings in imperfect osteogenesis. KARDAMATIS. Vichow's Arch. f. path. Anat., etc., Berl., 1913, ccxii, 436.

Processes of calcification in healthy and rachitic cartilage. A. HARTMANN. Sitzungsber. d. k. bayer. Akad. d. Wiss., Math.-physikal. Kl., 1913, 271.

Multiplecartilagenous exostoses. LALLEMANT. Fortschr. a. d. Geb. d. Röntgenstr., Hamburg., 1913, xx, No. 5.

X-ray examinations in a case of imperfect osteogenesis. E. FRÄNKEL. Ztschr. f. Röntgenk., 1913, xv, 179.

A typical injury of the medial condyle of the femur. EWALD. München. med. Wchnschr., 1913, lx, No. 30.

Periostitis due to overstrain and spontaneous fractures in the army. WOLF. Deutsche mil.-ärztl. Ztschr., 1913, xlii, No. 14.

Necrosis of the humerus at the middle third, caused by osteomyelitis; false ankylosis of the elbow. CORMIO. Policlin., Roma, 1913, xx, No. 26.

Acute osteomyelitis of the pubes. THOMSCHKE. Deutsche Ztschr. f. Chir., 1913, cxxiii, Nos. 3-4.

The Osgood-Schlatter disease. W. M. MINTZ. Verhandl. d. XII Russ. Chir. Kong., 1913, xii, 201. [520]

Paget's bone disease. P. MARIE and A. LERI. Handb. d. Neurol., 1913, iv, 471. [520]

Sporotrichosis localized in the bones and the lung and simulating tuberculosis. LAURENT. Loire méd., 1913, xxxii, No. 7.

Tuberculosis of bones and joints. G. L. STARR. Am. Med., 1913, viii, 472.

Surgical tuberculosis in children, with suggestions as to a method of treatment. A. H. TUBBY. Lancet, Lond., 1913, clxxxv, 137.

Conservative treatment of surgical tuberculosis. MENNE. Deutsche Ztschr. f. Chir., 1913, cxxiii, Nos. 3-4.

Heliotherapeutic treatment of surgical tuberculosis and tuberculosis of the bronchial glands by the seaside. R. FELTEN and F. STOLTZENBERG. Berl. klin. Wchnschr., 1913, l, 1062.

The out-door treatment of surgical tuberculosis. LOVETT and FISH. Boston M. & S. J., 1913, clxix, 145.

Osteosarcoma of the superior extremity of the tibia. PATEL. Progrès méd., Par., 1913, xlv, No. 29.

Hydatid cysts of the bones. BARDIN. Gaz. d. hôp., Par., 1913, lxxxvi, Nos. 79-80.

So-called osseous cysts. PEREZ. Policlin., Roma, 1913, xx, No. 7.

Osseous surgery and heliotherapy. AIMES. Progrès méd., Par., 1913, xlv, No. 28.

Familial chondrodystrophy. WAGNER. Arch. f. Gynäk., 1913, c, No. 1.

Pseudo-arthritis of the right fibula; scoliosis caused by inequality of the lower limbs. BROGA. Presse méd., Par., 1913, xxi, No. 54.

Diseases of joints and bone marrow. L. ELY. Am. J. Surg., 1913, xxvii, 247. [520]

The pathology of the knee-joint. BÄHR. Deutsche med. Wchnschr., 1913, xxxix, No. 30.

Injuries of the crucial ligaments of the knee-joint. GOETJES. Deutsche Ztschr. f. Chir., 1913, cxxiii, Nos. 3-4.

The pathology and treatment of hallux valgus. A. S. B. BANKART. Med. Press & Circ., 1913, xcvi, 33. [521]

Establishment of the tuberculous nature of arthritic exudates by the specific cutaneous reaction of a tuberculous guinea-pig. R. HAGEMANN. Med. Klin., Berl., 1913, ix, 947.

The conservative treatment of tuberculosis of joints. W. S. FENWICK. Brit. M. J., 1913, ii, 109. [521]

Some remarks on gout, rheumatism, and rheumatoid arthritis. T. M. ALLISON. Clin. J., 1913, xlii, 255.

Vaso-motor phenomena as a premonitory symptom in rheumatoid arthritis. J. LINDSAY. Clin. J., 1913, xlii, 268.

Arthritis catarrhalis (Volkman) during the development of a case of Barlow's disease. WOLFF. Arch. f. Orthop., Mechanothrap. u. Unfallchir., 1913, xii, 376.

A case of paratyphoid arthritis of the heel. J. TILGREN and A. TRÖLL. Wien. klin. Wchnschr., 1913, xxvi, 886.

Myosteoma developing after a diffuse hæmatoma following an injection of serum. DODIEAU. Bull. méd. de l'Algérie, Alger, 1913, xxiv, No. 11.

Myositis ossificans. S. L. McCURDY. Pittsburgh M. J., 1913, i, 32.

A bone encountered in the vastus externus muscle. PRES DE LIMA. Gaz. d. hosp. do Porto, 1913, vii, No. 14.

The operative paralysis of the triangular muscle. T. WALZBERG. Zentralbl. f. Chir., 1913, xl, 1040.

The etiology of the bursitides. A. SCHWARZ. Wien. med. Wchnschr., 1913, lxiii, 1854. [521]

Ossification of the tendon of Achilles. L. MEYER. Berl. klin. Wchnschr., 1913, l, 1304.

Tenoplasty of flexor tendons of fingers. J. B. MURPHY. Surg. Clin. J. B. Murphy, 1913, ii, No. 3.

The relation between gangrene and accidents. DUREK. Monatschr. f. Unfallh. u. Invalidenwes., 1913, xxx, No. 6.

Gangrene of the extremities and its treatment. H. EHRLICH and M. MARESC. Wien. klin. Wchnschr., 1913, xxvi, 1058. [522]

A case of progressive septic and necrotic phlegmon of the hand (hospital gangrene) treated after the method of Pfannenstiel. C. CRONQUIST. Allm. svep. Läkartidn., Stockholm, 1913, x, 769.

Study of the collateral circulation in some cases of spontaneous gangrene of the foot. J. E. THOMPSON. J. Am. M. Ass., 1913, lxi, 171.

Determination of the nutrition limit in gangrene of the foot. SANDROCK. Zentralbl. f. Chir., 1913, xl, No. 27.

Surgical treatment of gangrene of the lower extremities. LIDSKY. *Vrach. Gaz.*, St. Petersburg, 1913, xx, No. 28.

Fractures and Dislocations

Fractures and their treatment. MÜLLER. *Deutsche mil.-ärztl. Ztschr.*, 1913, xlii, No. 14.

New treatises on the treatment of fractures. BECKER. *Berl. klin. Wchnschr.*, 1913, l, No. 27.

Massage and mobilization in the treatment of fractures. J. J. CLARKE. *Universal Med. Rec.*, 1913, iv, 1.

Fractures and their treatment. J. A. HUTCHINSON. *Canad. M. Ass. J.*, 1913, iii, 555.

Gourdet's plaster of Paris apparatus with a protected loop in the treatment of complicated fractures. GUYOT and JEANNENEY. *J. de méd. de Bordeaux*, 1913, xliii, No. 30.

Extension treatment of fractures of the upper arm. CHRISTEN. *München. med. Wchnschr.*, 1913, lx, No. 28.

The treatment of fractures of the radius. A. TRÖLL. *Arch. f. klin. Chir.*, 1913, ci, 511.

Fractures of the carpal scaphoid in childhood and in adolescence. W. P. COUES. *Boston M. & S. J.*, 1913, clxix, 81.

Fracture and dislocation of scaphoid and semilunar bones. J. B. MURPHY. *Surg. Clin. J. B. Murphy*, 1913, ii, No. 3.

An apparatus for immobilization of the phalanges. LAVERMICOCCA. *Zentralbl. f. chir. u. mechan. Orthop.*, 1913, vii, No. 7.

Fracture of neck of femur; displacement of head on dorsum ilium. MURPHY. *Surg. Clin. J. B. Murphy*, 1913, ii, No. 3.

Separation of the epiphysis from the head of the femur. METZ. *Nederl. Tdschr. v. Geneesk.*, Amst., 1913, xii, No. 26.

Report of eighteen cases of separation of the lower femoral epiphysis at the Boston City Hospital. H. BINNEY. *Boston M. & S. J.*, 1913, clxix, 49. [522]

Diagnosis and treatment of fractures involving the knee-joint. J. B. BLAKE. *Ann. Surg.*, Phila., 1913, lviii, 27.

Rupture of the crucial ligaments of the knee and on fractures of the spine of the tibia. JONES AND SMITH. *Brit. J. Surg.*, 1913, i, 70. [523]

The technique of Steinmann's nail-extension. D. KULENKAMPFF. *Zentralbl. f. Chir.*, 1913, xl, 945.

A new apparatus for fixation and extension. H. WALDENSTRÖM. *Allm. sven. Läkartidn.*, Stockholm, 1913, x, 339.

Spontaneous ruptures of the long extensor tendon of the thumb following typical fractures of the radius; on the so-called drummer's paralysis. HEINECKE. *Deutsche Ztschr. f. Nervenhe.*, 1913, xlvii, Festschr. v. Strümpell, 229.

Subcoracoid dislocation of humerus with separation of tuberosity. J. B. MURPHY. *Surg. Clin. J. B. Murphy*, 1913, ii, No. 3.

A rare case of intercarpal luxation. MAYERSBACH. *Deutsche Ztschr. f. Chir.*, 1913, cxiii, Nos. 1-2.

Central luxation of the femur. HAUDEK. *Wien. klin. Wchnschr.*, 1913, xxvi, No. 30.

Pathological luxation of the hip falsely interpreted as congenital dislocation. FRÖLICH. *Presseméd.*, Par., 1913, xxi, 629.

A rare case of congenital luxation of the knee-joint. WACHTER. *Deutsche Ztschr. f. Chir.*, 1913, cxiii, Nos. 1-2.

Congenital backward luxation of the knee-joint. LAZARRAGA. *Med. Klin.*, Berl., 1913, ix, No. 26.

Dislocation of semilunar cartilage of knee. J. B. MURPHY. *Surg. Clin. J. B. Murphy*, 1913, ii, No. 3.

Fracture dislocation about the ankle-joint. R. E. FARR. *St. Paul M. J.*, 1913, xv, 345.

Surgery of the Bones, Joints, etc.

The operative treatment of fractures. W. BARTLETT. *Cleveland M. J.*, 1913, xii, 465.

The open treatment of fractures in general. G. S. FOSTER. *Med. Times*, 1913, xli, 7.

Irreducible malleolar fractures cured with a good functional result by operation. CHAPUT. *Rev. d'orthop.*, Par., 1913, xxiv, No. 5.

Autoplastic graft of fibula into humerus after resection for chondrosarcoma, with observations on bone-grafting. G. E. GASK. *Brit. J. Surg.*, 1913, i, 39. [523]

Free transplantation of fat into bone sinuses. E. KLOPPER. *Beitr. z. klin. Chir.*, 1913, lxxxiv, 499. [523]

Filling of bone cavities with free transplanted fat. KRABBEL. *Beitr. z. klin. Chir.*, 1913, lxxxv, No. 1.

Implantation of ivory for the repair of bones and joints. KÖNIG. *Beitr. z. klin. Chir.*, 1913, lxxxv, No. 1.

The mobilization of ankylosed joints. R. R. WREDEN. *Verhandl. d. XII Kong. russ. Ärzte, Moscow*, 1913, xii, 196.

Successful plastic operation on the elbow-joint by means of implantation of ivory prothesis. KÖNIG. *München. med. Wchnschr.*, 1913, lx, 1136. [524]

The ulnar longitudinal incision for operations in the region of the volar surface of the wrist-joint and of the hollow of the hand. G. F. VON SAAR and R. SCHWAMBERGER. *Zentralbl. f. Chir.*, 1913, xl, 993. [524]

Arthroplasty of hip; trochanter placed in acetabulum to form new joint. J. B. MURPHY. *Surg. Clin. J. B. Murphy*, 1913, ii, No. 3.

The end results of excision of the knee for tuberculosis with and without the use of bone plates. R. B. OSGOOD. *Boston M. & S. J.*, 1913, clxix, 123. [524]

End results obtained with Lexer's arthrodosis of the ankle-joint. SCHEWANDIN. *Arch. f. klin. Chir.*, 1913, ci, No. 4.

The effect of operations on the bony skeleton of the foot upon the growth and function of the foot. HAHN. *Beitr. z. klin. Chir.*, 1913, lxxxv, No. 2.

The surgical method of correcting contracture of the toes. PUTTI. *Riv. osp.*, Roma, 1913, iii, No. 12.

An analysis and study of 724 major amputations. W. L. ESTES. *Ann. Surg.*, Phila., 1913, lviii, 39.

Amputation of the arm and its shoulder girdle (amputation interscapulo-thoracica) in certain forms and recurrences of carcinoma of the breast. FRANKE. *Deutsche Ztschr. f. Chir.*, 1913, cxiii, Nos. 1-2.

Amputation of thigh in patient 108 years of age, followed by recovery. F. S. CLINTON. *J. Okla. St. M. Ass.*, 1913, vi, 93.

Amputation following traumatic transverse myelitis. O. S. RITCH. *N. Eng. M. Gaz.*, 1913, xlviii, 378.

Repair of finger-joints by implantation of toe-joints. R. GÖBEL. *München. med. Wchnschr.*, 1913, lx, 1598.

Free autoplastic transplantation of a phalanx from the toe to the left ring finger in a case of giant-cell sarcoma of the middle phalanx. STEVERS. *Beitr. z. klin. Chir.*, 1913, lxxxv, No. 1.

Transplantation of tendons into the thumb joint for contracture of the fingers of inflammatory origin. PLATONOFF. *Voienno-med. J.*, St. Petersburg, 1913, ccxxvii, June.

Free transplantation of periosteum. E. SCHEPELMANN. *Arch. f. klin. Chir.*, 1913, ci, 499. [524]

A case of free transplantation of half a joint. PETRASCHESKA. *Verhandl. d. wiss. Ver. d. Ärzte. d. städt. Obuchow-Krankh., St. Petersburg., 1913, xxii, 41.* [525]

Orthopedics in General

Orthopedic surgery. A. H. TUBBY. *Practitioner, Lond., 1913, xci, 88.*

A textbook on operative orthopedics. O. VULPIUS and A. STOFFEL. *Stuttgart: Enke, 1913.*

Practical progress in orthopedic surgery. J. K. YOUNG. *Dela. St. M. J., 1913, iv, 1.* [525]

Orthopedics and its employment, in particular following serious operations. TIMOGIEF. *Voenno-med. J., St. Petersburg., 1913, ccxxxvii, July.*

Congenital osteopsathyrosis. BAMBERG and HULD-SHINSKY. *Jahrb. f. Kinderh., 1913, lxxviii, No. 1.*

The pathology of idiopathic osteopsathyrosis. ZESAS. *Deutsche Ztschr. f. Chir., 1913, cxxii, Nos. 3-4.*

Partial defect of the sacrum, congenital pes varus, talipes equinus and vagus talus, malformation of the anus, paralytic symptoms, bilateral luxation of the coxa, and microcephaly. RENDU and VERRIER. *Rev. d'orthop., Par., 1913, xxiv, No. 5.*

A study of congenital dislocation of the hip with report of six cases. C. L. WASHBURN. *Physician & Surg., 1913, xxxv, 306.* [525]

Multiple congenital osteochondromata with degeneration of cranial nerves and muscular dystrophy; report of case. T. R. BOGGS. *Bull. Johns Hopkins Hosp., 1913, xxiv, 210.*

The familial occurrence of polydactylia and syndactylia. VOGEL. *Fortschr. a. d. Geb. d. Röntgenstr., Hamburg, 1913, xx, No. 5.*

Extrodactylia of the right foot. VEAU and LAMY. *Rev. d'orthop., Par., 1913, xxiv, No. 5.*

Recent studies on flat-foot and pes valgus. PELTESOHN. *Med. Klin., Berl., 1913, ix, No. 29.*

The physiological treatment of flat-foot. J. TESCHNER. *Med. Rec., 1913, lxxxiv, 63.*

Results obtained with Müller's operation for flat-foot. MÜLLER. *Beitr. z. klin. Chir., 1913, lxxv, No. 2.*

An operation for flat-foot. W. P. CARR. *Am. J. Surg., 1913, xxvii, 270.* [525]

A modified combined plaster of Paris and court-plaster dressing for the treatment of club-foot. SPRENGEL. *München. med. Wchnschr., 1913, lx, No. 27.*

Treatment of congenital club-foot. S. L. MCCURDY. *Pittsburgh M. J., 1913, i, 29.*

SURGERY OF THE SPINAL COLUMN AND CORD

The correction of fixed scolioses by Abbott's method. GRISEL. *Rev. d'orthop., Par., 1913, xxiv, No. 5.*

The Abbott treatment of rotary lateral curvature of the spine and details of the technique. KLEINBERG. *Surg., Gynec. & Obst., 1913, xvii, 32.* [526]

Scoliosis and chronic appendicitis. MAYET. *Paris chir., 1913, v, No. 4.*

Ankylosis of the spine. A. MCGLANNAN. *J. Alumni Ass. Coll. Physicians & Surg., Balt., 1913, xvi, 47.* [526]

Post-traumatic spondylitis or Kümmel's disease. CESTAN. *Toulouse méd., 1913, xv, No. 12.*

A clinical contribution on rhizomelic spondylosis. Policlin., *Roma, 1913, xx, No. 7.*

Aspiration of a case of spina bifida. M. E. BOLTON. *Mass. M. J., 1913, No. 6, 211.*

Graft of a part of the tibia upon the dorsal part of the spinal column in the treatment of Pott's disease. ALBEE. *Rev. de chir., Par., 1913, xxxiii, No. 7.*

Bone transplantation as a treatment of Pott's disease. H. C. ALDRICH. *J. Am. Inst. Homœop., 1913, vi, 28.* [526]

Methods of localization of spinal tumors with reference to their medical and surgical treatment. E. CASTELLI. *Med. Rec., 1913, lxxxiv, 1.* [526]

Enchondroma of the vertebral column. VALENTIN. *Beitr. z. klin. Chir., 1913, lxxiv, No. 1.*

Fractures of the fifth lumbar vertebra caused by compression. LEWANDOWSKY. *Med. Klin., Berl., 1913, ix, No. 26.*

Clinical case report of fractured vertebræ. F. C. KINSEY. *J. Mich. St. M. Soc., 1913, xii, 375.*

Spontaneous reduction of a dislocation of a cervical vertebra. W. C. BENTALL. *Brit. M. J., 1913, ii, 69.*

Transperitoneal operation on the vertebræ. W. MÜLLER. *Verhandl. d. Gesellsch. deutscher Naturf. u. Ärzte, 1913, ii, 181.*

The vertebral canal in the lumbar region in man. BAUDOUIN. *Arch. prov. de chir., Par., 1913, xxii, No. 5.*

A case of death following lumbar puncture. REUSCH. *Med. Klin., Berl., 1913, ix, No. 26.*

Tumor of the cauda equina. B. LICHTENBERGER. *Budapesti Orvosi Ujság, 1913, xi, 65.*

SURGERY OF THE NERVOUS SYSTEM

The theory of the chromaffin system. (Adnexa of the sympathetic nerve.) JACHONTOFF. *Russk. Vrach, St. Petersburg., 1913, xii, 527.*

Spastic paralysis of childhood and its treatment. K. BIESALSKI. *Deutsche med. Wchnschr., 1913, xxxix, 699.* [527]

The end results of operative treatment in thirty-three cases of spastic paralysis. H. E. HARRIS. *Boston M. & S. J., 1913, clxix, 82.* [527]

Experiences with the Stöffel operation for spastic paralysis. G. HOHMANN. *München. med. Wchnschr., 1913, lx, 1368.* [527]

Paralysis of the recurrent nerve in mediastinitis.

A. ADAM. *Arch. f. Laryngol. u. Rhinol., 1913, xxvii, 430.*

Traumatic thrombosis of the inferior vena cava with respect to life insurance. WEBER. *München. med. Wchnschr.*, 1913, lx, No. 26.

Post-operative thrombophlebitis. W. D. HAINES. *Lancet-Clin.*, 1913, cx, 87.

Arterial air embolism and the technique of artificial pneumothorax. F. JESSEN. *Deutsche med. Wchnschr.*, 1913, xxxix, 1245.

Fatty embolisms: the fatty embolism of the brain. NAVILLE and FROMBERG. *Arch. de méd. expér. et d'anat. path.*, Par., 1913, xxv, No. 4.

Transfusion of blood. TUFFIER. *J. méd. franc.*, Par., 1913, vii, No. 7.

Direct transfusion of blood. WERNECK. *Brazil med.*, Rio de Janeiro, 1913, xxvii, Nos. 25-26.

Prolonged intravenous infusions. M. FRIEDMAN. *München. med. Wchnschr.*, 1913, lx, 1022. [533]

Severe intestinal hæmorrhage in a case of typhoid fever, controlled by the intravenous injection of fresh human blood. OLIVIER. *Paris méd.*, 1913, No. 32.

Affections of the hæmatopoietic apparatus; also a contribution on tumors of the mediastinum. NICOL. *Beitr. z. path. Anat. u. z. allg. Path.*, Jena, 1913, lvi, No. 3.

Blood and Lymph Vessels

The relations of the inferior vena cava to the organs of the pelvic cavity. BOURCOURT. Paris méd., 1913, No. 34.

Aneurism of the posterior tibial artery, rupture of the sac; operation by the Matas method. PRIMROSE and ARCHIBALD. Canad. M. Ass. J., 1913, iii, 583.

The rôle played by the veins in arterio-venous aneurisms. NEY. Chir. arch. Veliaminova, St. Petersburg, 1913, xxix, No. 3.

The question of the employment of vessel suture in the treatment of aneurisms. TSCHERNIAKOVSKI. Deutsche Ztschr. f. Chir., 1913, cxxiii, Nos. 1-2.

Chronic thoracic aortitis, symmetrical arteritis of the tibial arteries, resulting in gangrene. MATTEI and REBOUL-LACHAUX. Marseille méd., 1913, I, No. 14.

Phlebitis. D. DUCKWORTH. Practitioner, Lond., 1913, xci, 1.

The medical treatment of phlebitis. H. VAQUEZ. Med. Press & Circ., 1913, xcvi, 88.

Treatment of varicose veins of the lower limbs by means of sapheno-femoral anastomosis. LENORMANT. Presse méd., Par., 1913, xxi, No. 54.

Treatment of varices with spiral incision. H. GEINITZ. München. med. Wchnschr., 1913, lx, 1257. [533]

The treatment of wounds of the large arteries, more especially those which are produced by bullets of small caliber. WEISS. Paris méd., 1913, No. 31.

Repair of a portion of the abdominal aorta by the carotid artery of the same animal. E. JEGER and H. JOSEPH. Arch. f. klin. Chir., 1913, ci, 535.

A case of extensive lymphosarcoma cured by operation. I. WILHEIM. Budapesti Orvosi Ujság., Sebészeti, 1913, xi, 22.

Ionization in the treatment of chronic adenitis. BEAUCHAMP and GOLDELWSKI. Sud méd., Marseille, 1913, xlv, No. 1962.

Poisons

The bacteriology of calf lymph. H. TEBBUTT. Australas. M. Gaz., 1913, xxxiv, 77.

A case of streptococcic septicaemia. BALDACCI. Gazz. d. osp. e d. clin., Milano, 1913, xxxiv, No. 81.

A case of septicaemia caused by pyocyaneus. T. INOKUCHI. Nippon-Geka-Gakkai-Zasshi, 1913, xiv, 21.

A case of staphylococcia. SAROLEA. Scalpel et liège méd., 1913, lxxv, No. 52.

Coli sepsis. L. FEJES. Beitr. z. klin. d. Infektionskrankh. u. z. Immunitätsforsch., 1913, i, 575. [534]

Communication of cutaneous germs by the knife. STEINEGGER. Zentralbl. f. Chir., 1913, xl, No. 26.

Surgical Therapeutics

Tetanus and Baccelli's treatment. DI MONTE. Policlin., Roma, 1913, xx, No. 27.

The treatment of tetanus in general and especially after the method of Baccelli. GULAEW. Policlin., Roma, 1913, xx, No. 27.

A case of tetanus cured after the method of Baccelli. RABITTI. Policlin., Roma, 1913, xx, No. 27.

Treatment of a case of tetanus according to the method of Baccelli. LEPORE. Policlin., Roma, 1913, xx, No. 27.

Case of tetanus cured by Baccelli's procedure of subcutaneous injection of phenic acid. PICCALUGA. Policlin., Roma, 1913, xx, No. 27.

Carbolic acid treatment of tetanus. RIGHI. Policlin., Roma, 1913, xx, No. 27.

Salicylic acid and carcinoma. NETOLITZKY. Wien. med. Wchnschr., 1913, lxiii, No. 27.

Experimental researches on the treatment of bacteriæmia by intravenous injection of sublimatin. SCHLOWSKY. Russk. Vrach, St. Petersburg, 1913, xii, 732.

Bolus alba. BURMEISTER. Zentralbl. f. Chir., 1913, xl, No. 29.

Hexamethylenamine in surgery. A. C. BURNHAM. Med. Rec., 1913, lxxxiv, 1. [534]

Hexamethylenamine in the treatment of infection in the bowel and bile tract and to prevent post-operative tympany. P. LA ROQUE. Therap. Gaz., 1913, xxix, 457.

Saturated bismuth injections. RECLUS. J. d. praticiens, Par., 1913, xxvii, No. 30.

The decalcifying action of oxalic acid. T. MILLER. Lancet, Lond., 1913, ii, 220.

The use of opium in gangrene. G. W. GAY. Therap. Gaz., 1913, xxix, 457.

Electrology

Improved X-ray apparatus employing alternating current. (Dessauer's "Reformapparat.") DESSAUER. Zentralbl. f. Röntgenstr., Radium u. verw. Geb., 1913, iv, 233.

Radiography and occupational accidents. DUCHAMP. Loire méd., 1913, xxxii, No. 7.

The X-ray and its possibilities in scientific research. R. H. PEPPER. W. Va. M. J., 1913, viii, 16.

Removal of foreign bodies under the control of radiocopy. MAUCLAIRE. Arch. gén. de chir., Par., 1913, vii, No. 6.

Radio-active substances and their therapeutic employment. WALTER. Fortsch. a. d. Geb. d. Röntgenstr., Hamburg, 1913, xx, No. 3.

Twenty-one new cases of radicular radiotherapy. ZIMMERN, COTTENOT and DARIAUX. Arch. d'électr. méd., expér. et clin., Bordeaux, 1913, xxi, No. 361.

The present status of röntgenotherapy in surgical tuberculosis. M. L. KARLIN. Chirurgia, St. Petersburg, 1913, xxviii, 633.

Conservative surgery from a röntgenologic standpoint. C. JACKSON. Am. Quart. Röntgenol., 1913, iv, 209. [534]

Treatment of cicatricial stenosis by means of electricity. POUCCÉ. Marseille méd., 1913, I, No. 13.

Radiology of carcinoma. LAZARUS. Berl. klin. Wchnschr., 1913, I, No. 28.

Experiences with radium treatment of malignant tumors. EXNER. Wien. med. Wchnschr., 1913, xxvi, No. 29.

The combined chemical and X-ray treatment of malignant tumors. SEELIGMANN. Deutsche med. Wchnschr., 1913, xxxix, No. 27.

Anatomical findings in carcinomata treated by means of mesothorium and Röntgen rays. HÄNDL. Arch. f. Gynäk., 1913, c, No. 1.

The physiological and therapeutic action of the derivatives of thorium. DE NOBELE. Arch. d'électr. méd., expér. et clin., Bordeaux, 1913, xxi, No. 361.

The most important causes of injuries due to electricity. H. ZANGGER. Naturwissenschaften, 1913, i, 375.

The treatment of surgical tuberculosis by means of artificial light. HAGEMANN. Deutsche med. Wchnschr., 1913, xxxix, No. 30.

Marine cure and heliotherapy. CONSTANTIN. Arch. méd.-chir. de Province, Poitiers, 1913, viii, No. 6.

Military and Naval Surgery

Military surgery. G. M. VLECH. Am. J. Surg., 1913, xvii, 259.

Demonstrations in military surgery. WIDERÖE. Norsk Mag. f. Lægevidensk., Christiania, 1913, lxxiv, No. 7.

Modern military surgery. H. KÜTTNER. Post-Graduate, 1913, xxviii, 605.

Some new helpful means in military surgery on the field.
MERMIGAS. Deutsche mil.-ärztl. Ztschr., 1913, xlii, 464.
 Abdominal wounds produced by modern fire-arms.
SALINARI. Clin. chir., Milano, 1913, xxi, No. 6.
 Dressing and transport of the wounded in naval warfare.

BARTHÉLEMY. Arch. de méd. et de pharm. mil., Par., 1913, xcix, June.
 Wounds by fire-arms, especially by the "Nagan" revolver.
ILINSKY. Voïenno-med. J., St. Petersburg, 1913, ccxxxvii, July.

GYNECOLOGY

Uterus

Histological diagnosis of tumors of the uterus. **SCHOTT-LÄNDER.** Arch. f. Gynäk., 1913, c, No. 1.
 Chorio-epithelioma. **C. B. KINYON.** Internat. J. Surg., 1913, xxvi, 237.
 The question of cancer of the uterus. **F. H. MARTIN.** Med. Herald, 1913, xxxii, 7.
 Statistical contribution on the morphology of uterine carcinoma. **J. OBATA.** Arch. f. Gynäk., 1913, xcix, 474. [535]
 The clinical position of carcinoma of the corpus uteri. **WEIBEL.** Arch. f. Gynäk., 1913, c, No. 1.
 The true prophylaxis against uterine carcinoma; a warning to gynecologists. **BOSSI.** Zentralbl. f. Gynäk., 1913, xxxvii, No. 27.
 The treatment of uterine cancer. **GUIERREZ.** Rev. ibero-am. de cienc. med., Madrid, 1913, xxix, No. 106.
 A comparison of the methods of treatment of carcinoma of the cervix. **P. ST. L. MONCURE.** Virginia Med. Semi-Month., 1913, xviii, 195.
 Surgical treatment of cancer of the uterus. **CAN DELA Y PLA.** Prensa med., la Habana, 1913, iv, No. 6.
 Treatment of cancer with mesothorium emanations. **PINKUSS.** Deutsche Gesellsch. f. Gynäk., Halle, 1913, May. [535]
 Giant cystic myomata. **LINGEN.** Zentralbl. f. Gynäk., 1913, xxxvii, No. 30.
 Röntgenotherapy of uterine fibromyomata. **CALATAYUD COSTA.** J. de radiol., Brux., 1913, vii, No. 2.
 A case of post-operative menstrual cystic hæmatoma. **DE ROUBILLE and ARRIVAT.** Arch. mens. d'obst. et de gynec., Par., 1913, ii, No. 6.
 A consideration of cystic tumors of the uterus of congenital origin. **VAUTRIN.** Ann. de gynec. et d'obst., 1913, x, 352. [536]
 A wire loop for the bloodless amputation of the uterus in vaginal operations. **SELLHEIM.** Zentralbl. f. Gynäk., 1913, xxxvii, No. 26.
 Technique of the amputation of the cervix of the uterus. **BONNEY.** Gynecologie, Par., 1913, xvii, May.
 Hysterectomies, cophorectomies and abdominal salpingectomies. **WERNECK.** Arch. brasil. de Med., 1913, iii, No. 4.
 Hæmorrhage into an angiomatous fibromyoma of the uterus and atheroma of the uterine arteries. **FLETCHER W. SHAW.** J. Obst. & Gynec. Brit. Emp., 1913, xxiv, 22.
 Etiology and organo-therapy of uterine hæmorrhages. **KALLEDEY.** Deutsche Gesellsch. f. Gynäk., Halle, 1913, May. [536]
 The treatment of genital hæmorrhages in woman by means of blood sera. **WEIL.** Gynecologie, Par., 1913, xvii, May.
 New views on menstruation and its time relationship to ovulation. **SCHRÖDER.** Monatschr. f. Geburtsh. u. Gynäk., 1913, xxxviii, No. 1.

An obstinate metrorrhagia. **K. F. L. KAISER.** Nederl. Tijdschr. v. Geneesk., Amst., 1913, No. 18, 1227.
 Endometritis. **J. F. MACKEY.** J. Mo. St. Med. Ass., 1913, x, 11.
 Double uterus and vagina. **C. S. LAWRENCE.** Southern M. J., 1913, vi, 477. [536]
 A case of hour-glass contraction of the uterus. **J. J. LEVIN.** S. African Med. Rec., 1913, xi, 259.
 Uterine prolapse. **ROBERT O. EARL.** St. Paul M. J., 1913, xv, 347.
 Congenital total prolapse of the uterus in a new-born affected with spina bifida. **RADWANSKA.** Gynäk. Rundschau, 1913, vii, No. 14.
 Surgical treatment of prolapse of the uterus and the vaginal walls. **PAUCHET.** Clinique, Par., 1913, viii, No. 28.
 An operation for prolapse complicated by hypertrophy of the cervix. **W. E. FOTHERGILL.** J. Obst. & Gynec. Brit. Emp., 1913, xxiv, 19.
 Procidentia of the uterus and rectum at the age of 27 years, with remarks on the treatment. **DOUGLAS DREW.** Lancet, Lond., clxxxv, 136.
 Procidentia uteri; Murphy's method of fixing the uterus. **J. B. MURPHY.** Surg. Clin. J. B. Murphy, 1913, ii, No. 3. [537]
 The etiology of retrodisplacement in virgins and nulliparæ. **PARISSE.** Gynecologie, Par., 1913, xvii, May.
 A new procedure for the relief of the retroverted uterus. **J. F. KUHN.** J. Okla. St. M. Ass., 1913, vi, 79. [537]
 The treatment of uterine retroflexion. **FRANQUE.** Med. Klin., Berl., 1913, ix, No. 28.
 Review of the literature and case reports of ruptured uterus. **CARL G. DAVIS.** Surg., Gynec. & Obst., 1913, xvii, 51. [537]
 The elimination of the danger of peritonitis in rupture and perforating injuries of the uterus. **SIGWART.** Arch. f. Gynäk., 1913, c, No. 1.
 The uterus of woman, its normal function and its rupture incident to labor. **J. WERBOFF.** Berlin: Karger, 1913. [538]
 An unwritten chapter in gynecology, uterine and adnexal syphilis. **CHASE.** Tex. St. J. Med., 1913, ix, 95.

Adnexal and Periuterine Conditions

The clinical significance of ruptures of follicles in the ovary. **FRANZ COHN.** Arch. f. Gynäk., 1913, xcix, 505. [538]
 Cure of an ovarian cancer with metastases by operation and subsequent X-ray treatment. **VON FRANQUÉ.** Deutsche Gesellsch. f. Gynäk., Halle, 1913, May. [539]
 Endothelioma of the ovary — with report of a case of mesothelioma of the ovary. **E. C. STEINHARTER.** Lancet-Clinic, 1913, cx, 84. [539]
 Successful and combined method of biochemic and X-ray treatment of malignant tumors; cure of a recurrent ovarian sarcoma with metastasis in the spinal column. **L. SEELIGMANN.** Deutsche Gesellsch. f. Gynäk., Halle, 1913, May. [539]

Ovarian hæmatoma and ovarian hæmorrhages. K. H. ÖHMANN. *Duodecim*, 1913, xxix, 55. [539]

Experimental researches on the process of cicatrization following ovarian resection. KRAUS. *Clin. chir.*, Milano, 1913, xxi, No. 6.

Pyosalpinx enucleation. FELIX W. GARCIA. *Med. Fortnight.*, 1913, xlv, 251.

Laboratory technique preparatory to pyosalpinx enucleation. ROBRET L. REBER. *Med. Fortnight.*, 1913, xlv, 253.

A method of ventrofixation combined with certain tubal sterilization by means of extra-abdominal displacement. DE WITT STETTEN. *Surg., Gynec. & Obst.*, 1913, xvii, 120. [539]

A new operation for the sterilization of the woman, with a future possibility of restoring the function. BLUMBERG. *Berl. klin. Wchnschr.*, 1913, l, 729. [540]

Treatment of sterility in woman. FUNK-BRENTANO and PLAUCHU. *Riv. internaz. di clin. e terap.*, 1913, viii, 81. [540]

"Pericolic Membrane" of the broad ligament. A. E. HERTZLER. *Surg., Gynec. & Obst.*, 1913, xvii, 60. [540]

The treatment of prolapse of the genitalia caused by anterior dislocation of the uterus by means of suture of the round ligaments to the levatores ani. ABADIA. *Arch. prov. de chir.*, Par., 1913, xxii, No. 5.

Rare distribution of resorbed dermoid contents. A. WOLFF. *Deutsche Gesellsch. f. Gynäk.*, Halle, 1913, May. [541]

External Genitalia

Septate vagina associated with a single uterus. HOLSTE. *Zentralbl. f. Gynäk.*, 1913, xxxvii, No. 26.

Colpotomy preliminary to abdominal operations in cases of hæmatocele. LIZCANO. *Siglo med.*, Madrid, 1913, lx, 3107.

Gonorrhœa of the female. J. S. JOHNSON. *Kentucky M. J.*, 1913, xi, 563.

The transperitoneal-vesicular route for the cure of certain operative vesico-vaginal fistulæ. LEGUEU. *Arch. urol. clin. de Necker.*, 1913, i, 1. [541]

Experiences with the vaccine treatment of gonorrhœa in the female. HEYMANN and MOOS. *Monatschr. f. Geburtsh. u. Gynäk.*, 1913, xxxvii, 623. [541]

Suppuration of the perineum in a subject infected with typhoid bacilli. L. LEVY. *Deutsche med. Wchnschr.*, 1913, xxxix, 1500.

Miscellaneous

X-ray treatment in gynecology. FÜTH. *Deutsche Gesellsch. f. Gynäk.*, Halle, 1913, May. [542]

X-ray treatment in gynecology. E. RUNGE. *Deutsche Gesellsch. f. Gynäk.*, Halle, 1913, May. [542]

X-ray therapy. WEITZEL. *Deutsche Gesellsch. f. Gynäk.*, Halle, 1913, May. [542]

X-ray treatment. HEIMANN. *Deutsche Gesellsch. f. Gynäk.*, Halle, 1913, May. [543]

Radiotherapy in gynecology. D'HALLUIN. *J. d. sc. méd. de Lille*, 1913, xxxvi, No. 26.

The internal secretions as they concern gynecology. S. W. BANDLER. *N. Y. M. J.*, 1913, xcvi, 111.

Tuberculosis of the female genitalia. DI BARTOLO. *Riv. osp.*, Roma, iii, No. 13.

Experimental contribution to the physiology of the female genitalia. O. O. FELLNER. *Deutsche Gesellsch. f. Gynäk.*, Halle, 1913, May. [543]

Imperfect development a factor in genesis of diseases of women. B. S. MOORE. *J.-Rec. Med.*, 1913, lx, 148.

Pelvic pain and backache in women; based on reports of two hundred cases. J. C. SHAW. *Internat. J. Surg.*, 1913, xxvi, 251.

Etiology and treatment of cystitis in women. F. W. GRIFFITH. *Southern M. J.*, 1913, vi, 7.

Cases illustrating certain urinary conditions in women associated with frequent or painful micturition. D. NEWMAN. *Clin. J.*, 1913, xlii, 193. [543]

The atriæ of post-operative infection of the female urinary tract. A. BAUEREISEN. *Ztschr. f. gynäk. Urol.*, Leipz., 1913, iv, 1. [544]

Transverse laparotomy in gynecology. PAUCHET. *Clinique*, Par., 1913, viii, No. 29.

The procedure of imbedding uterus and ovaries in paraffin. LOOPS. *Monatschr. f. Geburtsh. u. Gynäk.*, 1913, xxxviii, No. 2.

The use of serum in obstetrics and gynecology. A. MAYER. *Med. Cor.-Bl. d. württemb. ärztl. Landesver.*, 1913, lxxxiii, 261. [544]

The significance of infantilism in obstetrics and gynecology. A. MAYER. *Deutsche Gesellsch. f. Gynäk.*, Halle, 1913, May. [544]

Conservatism in gynecology. HOWARD CANNING TAYLOR. *Am. J. Obst.*, N. Y., 1913, lxviii, 28.

OBSTETRICS

Pregnancy and Its Complications

The thyroid in pregnancy. MARKOE and WING. *Bull. Lying-in Hosp.*, 1913, ix, 96. [545]

The significance of the ductless glands for the metabolism during pregnancy. E. LANDSBERG. *Deutsche Gesellsch. f. Gynäk.*, Halle, 1913, May. [545]

Abdominal pregnancy with living child. J. S. HORSLEY. *Surg., Gynec. & Obst.*, 1913, xvii, 58. [545]

Bilateral pyosalpinx; ectopic gestation. I. A. ARNOLD. *Internat. J. Surg.*, 1913, xxvi, 249.

Ectopic gestation; report of a case operated upon before rupture. JOHN K. FREEMAN. *Am. J. Surg.*, 1913, xxvii, 266.

Three cases of ectopic pregnancy. LIZCANO. *Siglo med.*, Madrid, 1913, lx, No. 3109.

A case of twin extra-uterine pregnancy. C. H. MULRONEY. *Iowa M. J.*, 1913, xx, 39.

Extra-uterine pregnancy; the importance of violent and repeated crises; supra-uterine hæmatocele. CHAPUT. *Rev. de gynéc. et de chir. abdom.*, Par., 1913, xx, No. 6.

The surgical importance of new formations of blood vessels in extra-uterine pregnancy and in abdominal tumors. A. P. GUBAREFF. *J. akush. i jensk. bolez.*, St. Petersburg, 1913, xxviii, 188.

Cystic kidneys and pregnancy. F. HEINSIUS. *Zeitschr. f. Geburtsh. u. Gynäk.*, 1913, lxxxiii, 429.

The relation of pyelitis due to bacillus coli to fecundity. MAYER. *München. med. Wchnschr.*, 1913, lx, No. 27.

Pregnancy and renal affections. SCHLAYER. *Monatschr. f. Geburtsh. u. Gynäk.*, 1913, xxxviii, No. 1.

Cardiac changes during pregnancy. S. W. SCHEWACHOFF. Arb. a. d. geburtsh.-gynäk. Klin. Prof. Redlich, St. Petersburg, 1913, i, 3. [545]

The relation of cardiac disease to pregnancy, labor, and puerperium. WALTHARD. Deutsche Gesellsch. f. Gynäk., Halle, 1913, May. [546]

Pregnancy and labor in organic heart disease. O. GRÖNÉ. Allm. sven. Läkartidn., Stockholm, 1913, x, 169. [546]

Ano-vulvar growths during pregnancy. RUDUAX. Clinique, Par., 1913, viii, No. 27.

Pregnancy following acromegaly. KALLEDAY. Zentralbl. f. Gynäk., 1913, xxxvii, No. 28.

A case of intestinal occlusion during gestation. LEVY-KLOTZ, CUNÉO and PINARD. Ann. de gynéc. et d'obst., Par., 1913, x, June.

Myoma operation during pregnancy. VAN DER HOEVEN. Nederl. Mandschr. v. verlosk. en Vrouwenz., 1913, ii, 285. [547]

Myoma, retroflexion, and pregnancy. VON DE VELDE. Nederl. Mandschr. v. verlosk. en Vrouwenz., 1913, ii, 295. [547]

The diagnosis and treatment of eclampsia. GEORGE W. KOSMAK. Bull. Lying-in Hosp., 1913, ix, 129. [547]

Clinical lecture on puerperal eclampsia and its treatment. J. VEIT. Med. Press & Circ., 1913, xcvi, 112.

Two cases of eclampsia cured by means of extract of the hypophysis. A. SCHLOSSBERGER. Deutsche med. Wchnschr., 1913, xxxix, 1046. [547]

A short review of our present knowledge concerning the pathology and etiology of eclampsia. ROBERT T. FRANK. Am. Med., 1913, viii, 482.

Observations on the toxæmias of pregnancy. AMAND ROUTH. Lancet, Lond., 1913, clxxv, 63. [547]

Cæsarean section. HUGH HOLMES CARR. W. Va. M. J., 1913, viii, 11. [548]

The uterine scar following the suprasymphyseal extraperitoneal Cæsarean section. KARL HARTMANN and HERMANN LOESCHKE. Gynäk. Rundschau, 1913, vii, 354. [548]

The present status of the Cæsarean section. EDWARD P. DAVIS. Am. J. Obst., N. Y., 1913, lxxviii, 12.

The chances for subsequent pregnancy after the classical Cæsarean section. VAN DER HOEVEN. Nederl. Mandschr. v. verlosk. en Vrouwenz., 1913, ii, 96. [548]

Cæsarean section performed for vaginal stenosis following an operation for vesico-vaginal fistule. W. BECKMAN. Ztschr. f. gynäk. Urol., Leipzig., 1913, iv, 95. [548]

Suprasymphyseal cervical Cæsarean section. LANGE. Monatschr. f. Geburtsh. u. Gynäk., 1913, xxxvii, 681. [548]

Cæsarean section on the dead and dying woman. O. KITNER. J. akush. i jensk. boliez., St. Petersburg., 1913, xxxviii, 539. [549]

Technique of Cæsarean section. J. VERT. Zentralbl. f. Gynäk., 1913, xxxvii, 713. [549]

Results obtained with the Cæsarean section in Russia during the last 25 years. N. POBEDINSKY. Zentralbl. f. Gynäk., 1913, xxxvii, 757. [549]

A case of septic abortion. HAMEL. Arch. med.-chir. de Prov., Poitiers, 1913, viii, No. 6.

An attempted abortion in a case of ectopic pregnancy, together with a contribution on violent ruptures of extra-uterine pregnancies. SINGER. Zentralbl. f. Gynäk., 1913, xxxvii, No. 26.

Quinine in the treatment of incomplete abortion. EDWARD ANDERSON. Maryland M. J., 1913, lvi, 172.

Management of miscarriage. L. A. ARNOLD. Kentucky M. J., 1913, xi, 599.

The conservative treatment of abortion and the results obtained. TRAUOGOTT. Med. Klin., Berl., 1913, ix, No. 27.

Labor and Its Complications

Some aspects of labor mechanism at the pelvic brim. A. K. PAINE. Boston M. & S. J., 1913, clxix, 154. [550]

A study of the induction and augmentations of labor pains. WALTER E. WELZ. Am. J. Obst., N. Y., 1913, lxxviii, 1.

Intervention in cases of narrow pelvic inlet. RIBAS. Bol. de med. y cir., Barcel., 1913, xxvii, No. 5.

The treatment of frontal presentation. LEHLE. Münch. med. Wchnschr., 1913, lx, 860. [550]

Some sequelæ of labor. BETHEL SOLOMONS. J. Obst. & Gynec. Brit. Emp., 1913, xxiv, 12.

Tumors of the ovary in their relation to labor and their secondary symptoms. PUECH. Montpellier méd., 1913, xxxvii, Nos. 28-29.

Acute dilatation of the stomach during labor and immediately thereafter. R. DE BOVIS. Semaine med., 1913, xxxiii, 169. [550]

Operative procedures in congenital high dystocia of the shoulder-blade. KÖNIG. Zentralbl. f. Chir., 1913, xl, 1186.

Uterine dystocia, secondary to mitral stenosis. ANNA RIES-FINLEY. Northwest Med., 1913, v, 196. [551]

Puerperium and Its Complications

A pathological condition which appeared during puerperium under the picture of cerebral tumor and eventuated in recovery. PELZ. Berl. klin. Wchnschr., 1913, l, No. 30.

Incidence of malaria in the puerperium. JAMES FREEMAN. Southern M. J., 1913, vi, 7. [551]

A case of puerperal eclampsia. J. L. FLEMING. Therap. Rec., 1913, viii, 208.

Report of a case of puerperal septicæmia. GERTRUDE M. JOHNSON. J. Mich. St. Med. Soc., 1913, xii, 365.

The passage of streptococci into the blood in the septic puerperium. HUSSY. Gynäk. Rundschau, 1913, vii, No. 14.

Post-abortion and post-partum hæmorrhages. SCHECHNER. Med. Klin., Berl., 1913, ix, No. 30.

Ovarian abscess after labor. ÖHMAN. Finska läk.-sällsk. handl., Helingsfors, 1913, lv, 447. [551]

Miscellaneous

Biological diagnosis of pregnancy. ENGELHORN. Zentralbl. f. Gynäk., 1913, xxxvii, 731. [551]

The sero-diagnosis of pregnancy by the dialyzation method. JELLINGHAUS and LOSEE. Bull. Lying-in Hosp., 1913, ix, 68. [552]

The diagnosis of pregnancy by means of the dialytic and optical methods. E. ABDERHALDEN. Deutsche Gesellsch. f. Gynäk., Halle, 1913, May. [552]

Abderhalden's sero-diagnosis. EVLER. Med. Klin., Berl., 1913, ix, No. 26.

Experiences with the Abderhalden test in the diagnosis of pregnancy. GUTMAN and DRUSKIN. Med. Rec., 1913, lxxxiv, 99.

Abderhalden's pregnancy reaction. A. MAYER. Deutsche Gesellsch. f. Gynäk., Halle, 1913, May. [552]

Abderhalden's reaction. PERDRIZET. Clinique, Par., 1913, viii, No. 30.

Abderhalden's ferment reaction. P. SCHÄFER. Deutsche Gesellsch. f. Gynäk., Halle, 1913, May. [552]

The specificity of the placenta splitting ferments of pregnancy serum. PETRI. Zentralbl. f. Gynäk., 1913, xxxvii, 731. [552]

Biological reactions and their importance for obstetrics and gynecology. PETRI. Monatschr. f. Geburtsh. u. Gynäk., 1913, xxxviii, No. 1.

The fat and cholesterin-content of the blood in pregnancy and the puerperium under normal and pathological conditions. DECIO. *Ann. di ostetr. e ginéc.*, 1913, xxxv, 281. [553]

Internal secretion and pregnancy. FRAENKEL. *Deutsche Gesellsch. f. Gynäk.*, Halle, 1913, May. [553]

The proof of the presence of spermatozoa in the cervical canal in two cases of rape eighteen hours after the perpetration of the crime. C. D. JOSEPHSON. *Allm. sven. Läkartidn.*, Stockholm, 1913, x, 345. [553]

Placental bacteræmia. WARNEKROS. *Deutsche Gesellsch. f. Gynäk.*, Halle, 1913, May. [553]

The location of the placenta. BORDÉ. *Ann. di ostetr. e ginéc.*, 1913, xxxv, 248. [554]

Placenta of giant infants. R. COSTA. *Ann. di ostetr. e ginéc.*, 1913, xxxv, 253. [554]

Intra-uterine sucking. ASCH. *Monatschr. f. Geburtsh. u. Gynäk.*, 1913, xxxvii, 701. [554]

A young human embryo. ZANGEMEISTER. *Deutsche Gesellsch. f. Gynäk.*, Halle, 1913, May. [554]

Origin of the amniotic fluid with pathological, experimental and clinical examinations of the function of the foetal kidneys. Leipzig and Vienna: Deuticke, 1913. [555]

The administration of oxygen to the foetus. GEORGE P. SHEARS. *Med. Rec.*, 1913, lxxxiv, 112.

Marked deformity of the limbs of a new-born in consequence of birth from a uterus bicornis unicollis. KALMONOWITSCH. *Gynäk. Rundschau*, 1913, vii, No. 14.

Blennorrhœa of the new-born and its prevention. L. I. BUBLITSCHENKAO. *Med. Rundschau*, 1913, xl, 549. [555]

Interruption of pregnancy and sterilization at a single séance by the abdominal path of access. SELLHEIM. *Monatschr. f. Geburtsh. u. Gynäk.*, 1913, xxxviii, No. 2.

On dilatation of the Fallopian tubes for sterility. HOPE T. LEWIS. *Brit. M. J.*, 1913, ii, 70.

The treatment of sterility by intra-uterine stems. REGINALD M. RAWLS. *Am. J. Obst., N. Y.*, 1913, lxviii, 35.

Simple surgical treatment of the umbilical stump. B. NÁDODY. *Zentralbl. f. Gynäk.*, 1913, xxxvii, 765. [556]

A new procedure for the enlargement of the pelvis. G. FREUDENTHAL. *Berl. klin. Wchnschr.*, 1913, i, 688. [556]

Pituitrin in obstetrics. D. G. VON HOYTEMA. *Nederl. Mandschr. v. verlosk. en Vrouwenz.*, 1913, ii, 296. [556]

Pituitary extract in obstetrics. J. M. H. ROWLAND. *Maryland M. J.*, 1913, lvi, 172. [556]

Pituitary extract in uterine inertia. J. CLIFTON EDGAR. *Am. J. Obst., N. Y.*, 1913, lxviii, 20.

A contribution to the study of pituitrin. N. SPROAT HEANEY. *Surg., Gynec. & Obst.*, 1913, xvii, 103. [557]

Surgery in obstetrics. BAISCH. *Klin.-therap. Wchnschr.*, 1913, xx, No. 27.

A study of forceps. ALBAN DORAN. *J. Obst. & Gynec. Brit. Emp.*, 1913, xxiv, 1.

Statistics of a Chinese policlinic. VORTISCH-VAN VLOTEN. *Arch. f. Schiffs. u. Tropen-Hyg.*, 1913, xvii, 253. [557]

GENITO-URINARY SURGERY

Kidney and Ureter

Etiology and technique of operation in struma supranalis cystica hæmorrhagica. H. KÜTTNER. *Verhandl. d. Gesellsch. deutscher Naturforsch. u. Ärzte.*, 1913, ii, 159.

The suprarenal capsules in cancer of the kidney. DE BERNE-LAGARDE and DE BEAUFOND. *Arch. urol. clin. de Necker*, 1913, i, 72. [558]

Five cases of calculus of the kidney. NEGRETE. *Rev. ibero-am. de cienc. med.*, Madrid, 1913, xxix, No. 106.

Calcified kidney. S. CLARK STEWART. *Urol. & Cutan. Rev.*, 1913, xvii, No. 7.

Report of five cases of nephrolithiasis with special reference to the symptomatology. M. P. WARMUTH. *Pa. M. J.*, 1913, xvi, 792.

On the differential diagnosis of appendicitis and nephrolithiasis. KROTOSZYNER. *Cal. St. J. M.*, 1913, xi, 287. [558]

Four cases of nephrolithiasis. LE CLERK-DANDROY. *Policlin.*, Brux., 1913, xxii, No. 12.

Kidney stone surgery. HERMAN L. KRETSCHMER. *Urol. & Cutan. Rev.*, 1913, xvii, No. 7.

Rare injuries of the kidneys. A. PLÜCKER. *Verhandl. d. Gesellsch. deutscher Naturforsch. u. Ärzte.*, 1913, ii, 167.

Serious disorganizing injury to the right kidney with very slight primary symptoms. M. H. SEARS. *Denver Med. Times*, 1913, xxxiii, 8.

Congenital defect of the kidney (agenesis renis) associated with uterus bicornis duplex cum vagina septa. GAITSCHMANN. *J. akusch. i jensk. bolez.*, St. Petersburg, 1913, xxviii, 59.

A study of the mechanical obstruction to the circulation of the kidney produced by the experimental acute toxic nephropathy. ALBERT A. GHOREYEE. *J. Exp. Med.*, 1913, xviii, 29. [558]

Unilateral fused kidney. ARTHUR STEIN. *Am. J. Obst., N. Y.*, 1913, lxviii, 43.

An experimental study of unilateral hæmaturia of the so-called essential type. PAYNE and MACNIDER. *Surg., Gynec. & Obst.*, 1913, xvi, 93. [559]

An unusual case of renal hæmaturia; unilateral chronic hæmorrhagic nephritis; decapsulation; apparent cure; recurrence; bilateral involvement; decapsulation of both kidneys six years later. WESLEY GROVE VINCENT. *Med. Rec.*, 1913, lxxxiv, 106.

Renal varix and hyperæmia as causes of symptomless renal hæmaturia. DAVID NEWMAN. *Brit. J. Surg.*, 1913, i, 4. [559]

An interesting case of renal hæmaturia, with three anomalous renal arteries. CHARLES M. HARPSTER. *Urol. & Cutan. Rev.*, 1913, xvii, No. 7.

Embryonal adeno-sarcoma of kidney. JEFFERSON D. BLOOM. *Urol. & Cutan. Rev.*, 1913, xvii, No. 7.

Unilateral polycystic kidney. CHARLES M. BARNETT. *Urol. & Cutan. Rev.*, 1913, xvii, No. 7.

Reconstruction of cystic kidneys, with a contribution on the development of cystic kidneys. FORSMAN. *Beitr. z. path. anat. u. z. allg. Path.*, Jena, 1913, lvi, No. 3.

Further experiences with luetic and post-luetic affections of the kidneys. BAUER. *Wien. klin. Wchnschr.*, 1913, xxvi, No. 27.

The value of pain as a symptom of renal disease. J. SWIFT JOLY. *Clinical J.*, 1913, xlii, 225.

Renal gonorrhoea. CHARLES HARPSTER. *Am. J. Urol.*, 1913, ix, 345.

Pyelitis as a clinical entity. P. I. NIXON. *Southern M. J.*, 1913, vi, 461.

Concerning a form of dull inter-costal neuralgia and its diagnostic value in affections of the renal pelvis. LAPINSKY. *Russk. Vrach.*, St. Petersburg, 1913, xii, No. 23.

Further experiences on the treatment of pyelitis by lavages of the renal pelvis. HOHLWEG. *München. med. Wchnschr.*, 1913, lx, No. 26.

Pyelitis and otitis of the middle ear in nurslings. GLASER and FLIESS. *Deutsche med. Wchnschr.*, 1913, xxxix, No. 30.

Chronic pyelonephritis in an infant. FAIRISE. *Arch. de méd., expér. et d'anat. path.*, Par., 1913, xxv, No. 4.

Pyelotomy. W. ISRAEL. *Ztschr. f. Urol.*, 1913, vii, 524. [559]

Two very painful cases of sclero-adipose perinephritis. NICOLICH. *J. d'urol.*, Par., 1913, iv, No. 1.

Lignous perinephritic phlegmon clinically and etiologically difficult to diagnose. THÈVENOT. *Lyon chir.*, 1913, x, No. 1.

Traumatic nephritis. ZOLLINGER. *Rev. suisse de méd.*, Basle, 1913, xiii, No. 20.

A form of experimental nephritis. J. FRANK CORBETT. *Urol. & Cutan. Rev.*, 1913, xvii, No. 7. [559]

Indications for operation in chronic nephritis. A. POUSSON. *J. d'urol.*, 1913, iii, 717. [560]

The surgical treatment of chronic nephritis. W. M. MYSCH. *Chir. arch. Veliaminova*, 1913, xxix, 419. [560]

The present standpoint in regard to nephritis and nephritis surgery. E. RUGE. *Ergebn. d. Chir. u. Orthop.*, 1913, vi, 565. [561]

Chronic nephritis from the point of view of surgery. J. MURARD. *Thèse de Lyon*, 1913. [561]

The physiology of the kidneys and the functional diagnosis of the kidneys in renal surgery and internal medicine. V. BLUM. *Leipzig and Vienna: Deuticke*, 1913. [562]

The early diagnosis of renal tuberculosis. R. C. BRYAN. *N. Y. M. J.*, 1913, xcvi, 1. [563]

Pathology and therapy of renal tuberculosis. KARO. *Terap. Obozrenié*, Odessa, 1913, v, No. 11.

Locating renal tuberculosis by means of radiography. PAPIN. *Arch. urol. clin. de Necker*, Par., 1913, i, No. 2.

Report of a case of renal tuberculosis. G. S. GORDON. *Am. J. Urol.*, 1913, ix, 340.

Three cases of surgical renal tuberculosis in infancy. ORATSON. *J. d'urol.*, 1913, iv, No. 1.

The effect of intravenous injection of acids on the excretion of staining substances through the kidney. OSWALD SCHWARZ. *Arch. f. d. ges. Physiol.*, 1913, cliii, 87.

Functional diagnosis of the kidney. BROMBERG. *Beitr. z. klin. Chir.*, 1913, lxxxv, No. 1.

Functional tests of the kidneys and their importance for therapy. ROTH. *Med. Klin.*, Berl., 1913, ix, No. 26.

The uræmic constant of Ambard; the coefficient of the secretion of urea for the determination of the functional value of the kidney. BONANOME. *Policin.*, Roma, 1913, xx, No. 30.

On the use of phthalein to determine the renal function prior to prostatectomy. W. D. HAMILTON. *Lancet-Clin.*, 1913, cx, 33.

The determination of the hæmorenal index in tests of the function of the kidney. R. BROMBERG. *Deutsche med. Wchnschr.*, 1913, xxxix, 1358.

The function of the nerves of the kidneys. E. ROHDE and PH. ELLINGER. *Zentralbl. f. Physiol.*, 1913, xxvii, 12.

Surgery of the kidney. W. E. ALTON. *Iowa M. J.*, 1913, xx, 27.

Cystoscopic diagnosis of ureteral calculus and its removal by the vaginal path of access. HEINSIUS. *Ztschr. f. Geburtsh. u. Gynäk.*, 1913, lxxiii, 441.

Prolapse of the ureters through the urethra and notes on the histology of oedema bulbosum. FRANQUE. *Monatsschr. f. Geburtsh. u. Gynäk.*, 1913, xxxviii, Suppl. No.

Some new data on the etiology of hydronephrosis (congenital malformation of the ureter). N. A. MICHAJLOW. *Ztschr. f. Urol.*, 1913, xii, 564.

Contribution to the clinical study of strictures of the ureter; large strictures. DESNOS. *J. d'urol.*, 1913, iii, 739. [563]

Therapeutic catheterization of the ureters. BLUM. *Wien. med. Wchnschr.*, 1913, lxxiii, No. 27.

Cystic dilatation of the vesical end of the ureter. RUMPEL. *Ztschr. f. Urol.*, 1913, vii, 541.

Bladder, Urethra, and Penis

Some remarks on the diagnosis of vesical complications in appendicitis and other lesions of the abdominal viscera. CHARLES CAILLET. *Am. J. Urol.*, 1913, ix, 355.

A case of foreign body in the bladder, removed by suprapubic incision. FÉCHINE. *Vofenno-med. J.*, St. Petersburg, 1913, ccxxxvii, June.

Intraperitoneal rupture of the bladder; laparotomy; recovery. STINCER. *Rev. de med. y cir. de la Habana*, 1913, xviii, No. 12.

Electro-coagulation of tumors of the bladder. LEGUEU. *Arch. urol. clin. de Necker*, Par., 1913, i, No. 2.

A case illustrating the efficiency of the high frequency current in the treatment of tumors of the bladder. J. DELINGER BARNEY. *Boston M. & S. J.*, 1913, clxix, 19. [564]

Cystitis. M. L. WILBANKS. *Tex. Med. News*, 1913, xxii, 1454.

Cystitis: acute and chronic. GEORGE WARFIELD. *Mass. M. J.*, 1913, vii, 253.

A case of cystitis. E. STUVER. *Denver Med. Times*, 1913, xxxiii, 9.

A contribution to the study of ectopia vesicæ. KARL BRANDL. *Am. J. Urol.*, 1913, ix, 333.

A simple procedure for suture of the bladder combined with cystopexy. HACHE. *Arch. méd.-chir. de Prov.*, Poitiers, 1913, viii, No. 6.

Mad's operation in exstrophy of the bladder. KUSTNETZKY. *Pract. Vrach.*, St. Petersburg, 1913, xii, 323.

Applications of chromocystoscopy. PULIDO MARTIN. *Siglo med.*, Madrid, 1913, lx, No. 3110.

Diagnosis and treatment of multiple urethral calculi, with report of unusual case. W. C. STEVENS. *J. Am. M. Ass.*, 1913, lxi, 86. [564]

Stenosis of the urethra and urinary lithiasis. THÈVENOT. *Progrès méd.*, Par., 1913, xlv, No. 26.

Treatment of ruptures of the urethra. WERNECK. *Brazil med.*, Rio de Janeiro, 1913, xxvii, No. 22.

Irreducible traumatic stenosis of the urethra; urethrectomy and urethrorrhaphy; recovery. COCHEZ. *J. d'urol.*, Par., 1913, iv, No. 1.

Treatment of inflammatory stenoses of the urethra by means of electrolytic dilatation. DESMONTS. *Sud méd.*, Marseille, 1913, xlv, No. 1962.

Congenital stricture of the prostatic urethra with bladder hyperplasia, urethral dilatation and multiple abscesses of both kidneys. W. H. JORDAN. *J. Am. M. Ass.*, 1913, lxi, 244. [564]

Lesions of the posterior urethra in urinary neurasthenia. MARSAN. *Arch. urol. clin. de Necker*, Par., 1913, i, No. 2.

Lesions of the posterior urethra during urinary neurasthenia. LEGUEU. *Clinique*, Par., 1913, viii, No. 28.

Gonorrhœal urethritis with complications. J. J. WALKER. N. Mex. M. J., 1913, x, 107.

Abscess of the cavernous part of the urethra. TIMOFEEFF. Chir. arch. Veliaminova, St. Petersburg., 1913, xxix, No. 3.

Internal urethrotomy. FRONSTEIN. Vrach. Gaz., St. Petersburg., 1913, xx, No. 25.

Double epididymic urethras. LEBRUN. J. d'urolog., Par., 1913, iv, No. 1.

Mistaken sex in consequence of penoscrotal hypospadias. ZURHELLE. Deutsche med. Wchnschr., 1913, xxxix, No. 27.

Peritomy. SALZMANN. Wien. med. Wchnschr., 1913, lxxiii, No. 30.

The treatment of acute blennorrhœa. LESHNEV. Terap. Obozrenié, Odessa, 1913, v, No. 11.

Genital Organs

Traumatic total loss of skin of the male sexual organs. K. BELFRAGE. Nord. med. Ark., 1913, xlv, 11. [564]

Gangrene of the scrotum, chancroid and epithelioma of the penis occurring simultaneously in same patient; recovery. W. C. BRYANT. Pittsburgh M. J., 1913, i, 39.

A case of perineo-scrotal dermoid cysts. A. CARLESS. Brit. J. Surg., 1913, i, 39. [564]

Castration and operation for varicocele and hydrocele without wounding the scrotum. C. A. BUCKLIN. Med. Rec., 1913, lxxxiv, 108. [565]

Recurrence of hydrocele after radical treatment. D. TAIT. Calif. St. J. Med., 1913, xi, 258. [565]

The hydrocele operation. MÜLLER. Zentralbl. f. Chir., 1913, xl, No. 29.

Acute orchitis in children. OMBREDANNE. Presse méd., Par., 1913, xxi, No. 59.

Orchidism and prostatitis; the stages of cure. VILLETTE. J. d. sc. méd. de Lille, 1913, xxxvi, No. 26.

Ectopia testis. E. M. ECCLES. Clin. J., 1913, xlii, 241. [565]

Structure and pathogenesis of embryonic teratoma of the testicles. MEYER. Frankf. Ztschr. f. Path., Wiesb., 1913, xiii, No. 2.

Fecundity of patients affected with bilateral tuberculosis of the epididymis. FURBINGER. Deutsche med. Wchnschr., 1913, xxxix, No. 29.

Two cases of spermatic cyst associated with absence of the vas deferens. DE FRANCISCO. Riforma med., 1913, xxix, No. 28.

Operations on the seminal vesicles. VOELCKER. Arch. f. klin. Chir., 1913, ci, No. 4.

Affections of the prostate gland. PORTNER. Med. Klin., Berl., 1913, ix, No. 26.

On the value of cauterization by the high frequency current in certain cases of prostatic obstruction. A. R. STEVENS. N. Y. M. J., 1913, xcvi, 170. [566]

Carcinoma of the prostate. GEBELE. Zentralbl. f. d. Grenzgeb. d. Med. u. Chir., 1913, xvi, 579. [566]

Metastatic carcinoma of the prostate simulating a lymphomatosis. LUNDSGAARD. Virchow's Arch. f. path. Anat., etc., Berl., 1913, ccxiii, No. 1.

Carcinoma of the prostate gland simulating lymphomatosis. LUNDSGAARD. Hosp.-Tid., Kjøbenh., 1913, lvi, No. 27.

Carcinoma of the prostate gland; a study of thirty-three cases. R. J. WILLIAN. Brit. M. J., 1913, ii, 60. [566]

Slight and marked hypertrophies of the prostate. DE GRÄUWE. J. Méd. de Brux., 1913, xviii, No. 26.

Some conditions simulating prostatic hypertrophy. C. WALLACE. Clin. J., 1913, xlii, 209. [567]

The post-operative complications of prostatectomy. HAGNER and FULLER. Surg., Gynec. & Obst., 1913, xvii, 110. [567]

Simplified prostatectomy by the suprapubic way. D. W. BASHAM. Med. Herald, 1913, xxxii, 7.

The technique of suprapubic prostatectomy. BRUNNER. Zentralbl. f. Chir., 1913, xl, No. 28.

Total prostatectomy in the so-called prostatic hypertrophy. GRINENKO. Dissertation, St. Petersburg., 1913. [567]

Prostatectomy in the aged. H. A. MOORE. Interst. M. J., 1913, xx, 648. [568]

Drainage of the bladder in suprapubic prostatectomy. C. MÜLLER. Ztschr. f. urol. Chir., 1913, i, 393.

Miscellaneous

Elimination of errors in the X-ray diagnosis of urinary calculus. H. SHENTON. Lancet, Lond., 1913, clxxxv, 77.

The shortcomings of ordinary clinical data in urological diagnosis. STANTON. Internat. J. Surg., 1913, xxvi, 237.

The presumptive diagnostic value of the specific reaction of the urine in carcinomatosis. BALDONI. Boll. d. sc. med., Bologna, 1913, lxxxiv, No. 6.

Transfusion of blood in profuse urinary hæmorrhages. LEGUEU. J. d'urolog., Par., 1913, iv, No. 1.

Staphylococcal of urinary origin. LEGUEU. Progrès méd., Par., 1913, xlv, No. 30.

The content of colloidal nitrogen in the urine of cancerous subjects. A. P. KONIKOV. Russk. Vrach, St. Petersburg., 1913, xii, 927.

Urolithiasis and bilharziasis. PFISTER. Arch. f. Schiffs- u. Tropen-Hyg., 1913, xvi, 309. [568]

Experiences with arthigon in complications of gonorrhœa. E. FREUND. Wien. med. Wchnschr., 1913, lxxxi, 1550. [569]

The need of the microscope in the treatment of gonorrhœal urethritis and prostatitis. J. BROADMAN. N. Y. M. J., 1913, xcvi, 1.

Serodiagnosis of gonorrhœal affections. J. A. FINKELSTEIN and T. M. GERSCHUN. Russk. J. koshnych i vener. bol'ez., St. Petersburg., 1913, xxv, 272.

A routine method of examination in gonorrhœa in the male as a guide to treatment. F. H. PICKIN. Lancet, Lond., 1913, clxxxv, 76.

The prophylaxis and treatment of gonorrhœa. G. LUND. Med. Fortnight., 1913, xlv, 255.

Urogenital tuberculosis. B. RIHMER. Budapesti Orvosi Ujság., 1913, xi, 119.

Mid-operative diagnosis in urologic operations. G. KOLISCHER. J. Am. M. Ass., 1913, lxi, 174. [569]

Agentialism and hypogenitalism; connective tissue diathesis as a cause of multiglandular disturbances (insuffisance pluriglandulaire). J. WIESEL. Handb. d. Neurol., 1913, iv, 407.

A case of exploded urethrascope lamp; removal of fragment without operation or subsequent symptoms or sequels. V. C. PEDERSON. Med. Rec., 1913, lxxxiv, 158.

SURGERY OF THE EYE AND EAR

Eye

Severe injuries to the eyes and face by so-called water-core and zodiac golfballs. OHLEMANN. *Klin.-therap. Wchnschr.*, 1913, xx, 604. [570]

The importance of accurate diagnosis of affections of the eye. C. KOLLOCK. *J. South Car. M. Ass.*, 1913, ix, 177.

Some remarks upon the diagnosis and treatment of lacrimal affections. S. STEPHENSON. *Clin. J.*, 1913, xlii, 252. [570]

Clinical lecture on the treatment of glaucoma with particular reference to the newer operations. S. STEPHENSON. *Med. Press & Circ.*, 1913, xcvi, 58. [570]

The treatment of tracheoma from a surgical standpoint. DE CARADENC. *J. M. Ass. Ga.*, 1913, iii, 75.

Sarcoma of the iris. J. LOCKHART. *Australas. M. Gaz.*, 1913, xxxiv, 3.

Cylindroma of the lower eyelid, (the nascent type of cylindroma). DUCLOS. *Ann. d'oculist.*, 1913, cxlix, 445.

Capillary angioma of the retina. H. FRENKEL. *J. Ophth., Otol. & Laryngol.*, 1913, xix, 268. [570]

The genesis of orbital cysts and of anomalies of the retina and the choroid which occur in microphthalmus. R. BERGMEISTER. *Arch. f. Ophth.*, 1913, lxxxv, 1.

Some common ocular manifestations secondary to disease of the nose and accessory sinuses. H. H. TURNER. *Pittsburgh M. J.*, 1913, i, 49.

A report of a case of tuberculous ophthalmia. D. V. SMITH. *Physician & Surg.*, 1913, xxxv, 312.

ABSTRACTS OF CURRENT LITERATURE

GENERAL SURGERY

SURGICAL TECHNIQUE

SEPTIC AND ANTISEPTIC SURGERY

Kozlowki, B.: Alcohol Operating Gloves (Alkohol-operationshandschuhe). *Zentralbl. f. Chir.*, 1913, xl, 1038. By *Zentralbl. f. d. ges. Chir. u. i. Grenzgeb.*

In view of the fact that alcohol hardens the skin and fixates cutaneous germs, the author uses in his operations sterile thread gloves soaked in alcohol and put on moist over the disinfected hand. He has never noted any injury to the skin of the hands even after many hours of contact with the alcohol, nor any injury to the tissue in the operative field. The gloves are frequently moistened again with alcohol during the operation or replaced by fresh ones soaked in alcohol.

GENEWEIN.

ANÆSTHETICS

Buxton, W.: A Dosimetric Method of Administering Chloroform. *Tr. Internat. Cong. Med.*, Lond., 1913, Aug. By *Surg., Gynec. & Obst.*

The principles involved in this method are as follows:

1. Chloroform acts upon the tissues in proportion to the strength of its vapor in mixtures with air or liquids.
2. The action of chloroform is progressive, the narcosis becoming deeper when the chloroform is given over a long period in constant dilution.
3. Different body tissues are affected in a similar way though in different degrees. Percentages of vapor below 1 per cent do not produce anæsthesia but interfere with the temperature and metabolism. Higher percentages induce anæsthesia, lower blood pressure, and interfere with respiration.
4. Chloroform is an ultimate protoplasm poison.
5. Chloroform reacts decidedly more vigorously upon pathological tissues and in abnormal conditions such as asphyxia, anæmia, fatty or degenerative changes in tissue cells, etc.

6. A definite percentage of vapor will produce anæsthesia but greater amounts produce deeper narcosis which interferes with vital functions. The amount of chloroform necessary to maintain a steady level of anæsthesia varies inversely with the length of time it is inhaled.

7. The amount of vapor required to induce and maintain anæsthesia is less for individuals of impaired vitality and for children.

The extent to which chloroform passes from the air into the blood stream is impossible to gauge. The anæsthetic in the tissue cells causes a lessening, and ultimately, a cessation of bio-chemical function, this interference being directly proportional to the percentage strength of the chloroform introduced. Waller has shown that nerve tissue first becomes paralyzed, then loses its conductivity, a uniform result following a known percentage strength of vapors. The degree of hæmolysis is difficult to estimate because the influence exerted by many factors in human beings is unknown. Chloroform causes a fall of blood pressure, heart weakness, possibly due partly to dilatation, and a lessening of vasomotor control. These effects can be controlled by lessening the amount of chloroform given *pari passu* with the length of time that it is administered, providing environing conditions remain the same. The effects are influenced profoundly by asphyxia, hæmorrhage, or traumatic shock. Oxygen restrains the effect of chloroform upon the tissues, and normal blood protects them. A percentage of chloroform that will produce a safe anæsthesia in a normal individual may be dangerous for one whose blood is vitiated by disease and especially by anoxæmia.

It is agreed that double the anæsthetic dose constitutes the lethal dose. Chloroform affects tissues in the following order: (1) nerve tissue, the highly differentiated first; (2) heart muscle; (3) striped

voluntary muscle; and (4) involuntary muscle fibre.

Upon this fact anæsthesia depends; otherwise the production of unconsciousness would be impossible. The most highly differentiated portion of the brain is first thrown out of function, then the lower ganglia are affected while blood pressure falls and respiratory functions become more limited. The myocardium is affected rapidly and early and soon loses its power of contracting. The normal reflex mechanism is so affected that abnormally severe inhibitions are elicited and metabolism may be profoundly influenced. From the foregoing the author believes that the effects of chloroform are due to the actual vapor strength rather than to the actual amount of drug used, not considering, of course, the result from toxic quantities. Therefore, the dosimetric system is advocated as a means of limiting the strength of the admixture used, not only in inducing anæsthesia but in maintaining it as the tissues become more and more under the influence of the drug, in order to be sure that its effect is merely anæsthetic in character and not toxæmic.

In the induction of anæsthesia, it has been found that the organism will tolerate a high percentage vapor if the strength is reached gradually, while its sudden use results in collapse and even death. For a normal person it has been found that a strength of about 2 per cent will induce anæsthesia; that less will cause sleep only; and that more will embarrass the respiration and circulation. In spite of these facts, the average administrator experiments upon his patients, and his results depend upon his personal acumen as an experimenter. Failure is often certain because of his inability to estimate subtle tissue changes and to anticipate contingencies of shock and actual tissue injury. These considerations bear equally upon the period of maintenance when an overdose of chloroform may put the patient into a state of toxæmia even though his life has never been in jeopardy during the administration.

There are three dosimetric methods: (1) an open method; (2) the administration of mixtures; (3) the administration by instruments which present atmospheres of known strength or by inhalers which determine an admixture of chloroform and air the strength of which is known and can be varied by the operator with great accuracy. The open method is comparatively accurate, but only in the hands of those with the utmost skill and experience and when disturbing factors such as variations in depth and frequency of respiration, room temperature, and air currents can be eliminated. With mixtures, the same objections hold true, and, in addition, it is impossible to obtain any accurate percentage value for the chloroform which is given off because of the difference in the boiling points of the ingredients.

Many mechanical inhalers are on the market—Bert's, Snow's, Clover's and the Roth Drager apparatus—but all of these allow the 2 per cent

strength to be exceeded. The regulators of Dubois, Waller, and Alcock are exact but bulky. The author has used chiefly the Vernon-Harcourt regulator and his experience has been that 2 per cent need not be exceeded. In very muscular and obese subjects rapid induction with nitrous oxide and ether preceded by gr. 1/100 of atropin has been serviceable. The author uses oxygen in order to maintain the vigor of the tissues and to lessen shock and prevent "weeping" when large areas are incised or denuded. When a deep narcosis is necessary a dosimetric inhaler enables the anæsthetist to better control the higher percentages when he is working in the danger zone. Cyanosis is due not to the inhaler but to preventable complications which may arise with any method of giving chloroform. Nasal and mouth tubes are supplied with the common inhalers and the vapor may be inspired by Crile's method or can be propelled by a foot bellows.

After dosimetric administration the patient has a normal color and there are few after-effects. After the old method, on the other hand, the patient is pale and drawn; he vomits and is in a greater or less degree of collapse.

The controlling principle of this method, which the author considers the only safe means of administering the drug, is to gradually increase the percentage of chloroform vapor, and, as soon as anæsthesia is established, to lower it to the point where the intake equalizes the output from the lungs. No matter what changes may occur in the patient's breathing, a safe strength—2 per cent—should not be exceeded, and even struggling does not call for a restriction of the supply.

E. K. ARMSTRONG.

Descarpentries, M.: General Anæsthesia by Intramuscular Injections of Ether; a New Anæsthesia Apparatus, Particularly for Etherization, Based Upon the Principles Derived from the Latter (*Anesthésie générale par les injections intramusculaires d'éther; Un nouvel appareil à anesthésie, en particulier à étherisation, basé sur les principes qui en découlent*). *Tr. Internat. Cong. Med.*, Lond., 1913, Aug.

By Surg., Gynec. & Obst.

General anæsthesia may be induced without danger by intramuscular injections of ether if it is given in successive small doses (about 5 cc.) and injected slowly into large muscle masses or thick aponeuroses to limit the vaporization and keep the vapor under tension.

The best place is the gluteal muscles. The entire dosage varies, according to the weight of the patient, about a cubic centimeter to a kilogram of weight. There is little danger of giving too much. The first pain is keen, but is very quickly over. After the anæsthesia, the patient complains of a feeling of heaviness in his legs. To avoid the initial pain, the anæsthesia should be begun with a few inhalations of ethyl chloride or chloroform. A few drops of chloroform may be given also without any danger while the patient is anæsthetized. This makes

the narcosis more profound and permits of the use of a smaller quantity of ether.

The method is simple; it greatly facilitates operations about the face and neck, and dispenses with the necessity of having an anæsthetist. It enables a surgeon to operate alone in emergency cases under general anæsthesia. It differs from ordinary etherization in that by it the ether vapor enters the blood without any admixture of carbon dioxide and is warm (42° – 33°) when it enters the alveoli of the lungs.

The anæsthesia apparatus described is constructed to carry out these two principles. It gives a rapid, calm, and regular narcosis without pulmonary complications and contra-indications. It combats anæsthetic shock in that it does not lower the patient's temperature. During the first ten minutes it raises the rectal temperature from two to five tenths of a degree.

The apparatus permits of obtaining the anæsthetic mixture that is most favorable to cure. Some patients abhor the odor of ether; in such cases anæsthesia can be begun with 10 cc. of ethyl chloride. The apparatus does away with the exhalation of ether vapor in the operating and the risk of explosion. The author believes that a surgeon who works daily in ether vapor becomes gradually fatigued and intoxicated with ether.

Gwathmey, J. T.: Oil-Ether: an Attempt to Abolish Inhalation Anæsthetics. *Tr. Internat. Cong. Med.*, Lond., 1913, Aug.

By Surg., Gynec. & Obst.

Experiments on animals, under the direct supervision of Prof. George Wallace, of the Pharmacological Department of Bellevue Medical College, were conducted for the purpose of studying the anæsthetic value of ether when introduced in solution into the rectum. A 5 per cent solution of ether in normal saline solution was used first, about 500 cc. being injected into the colon. In order to reduce the bulk, Gwathmey suggested employing oil instead of saline solution. Experiments under the supervision of Prof. Charles Baskerville, Director of the Department of Chemistry of the College of the City of New York, were then made to determine the relative rapidity with which the ether escaped from the oil in which it was dissolved, the solutions compared being of the same strength and subject to the same temperature. Cod-liver oil, olive oil, neats-foot oil, carron oil, paraffin (Russian mineral oil), milk, and cream were used. It was found that carron oil parted with the ether in nearly one fourth of the time that was required by the other substances.

Ten successful experiments were carried out upon dogs, with complete anæsthesia and no alarming symptoms. The ether was given in solution in cotton-seed oil from 55 to 75 per cent, the amount of ether injected being from 50 to 75 cc. The shortest time required for the establishment of surgical anæsthesia was five minutes; the longest time, fifty

minutes. The duration of the anæsthesia after the ether injection was stopped averaged about one hour. In no case was there evidence of more than a mild irritation of the rectum following the ether injection, and such irritation passed off within twenty-four hours.

In the clinical experiments the oil-ether solutions, varying from 40 to 75 per cent, were employed. It was found that solutions of 75 per cent proved most satisfactory in both animal and human subjects. The most gratifying results were obtained from the use of 200 to 300 cc. of a mixture of 6 oz. of ether and 2 oz. of oil. Anæsthesia thus induced was ideal. Pulse and respiration were normal; there were no mucous râles, and no after-effects such as nausea or diarrhœa.

One of the underlying thoughts in developing oil-ether anæsthesia was to prevent certain dangers that attend intravenous anæsthesia. The fact that the only apparatus needed is a small catheter and a funnel into which to pour the mixture, is a strong argument in favor of this method. To a practitioner compelled to work alone it should be of inestimable benefit. On account of the gradual and rapid evaporation from the lungs it would appear to be at least a comparatively safe method of inducing anæsthesia. Mucus and saliva are absent, and the patient's lungs and stomach are spared.

The preparation of the patient is the same as for ether-vapor anæsthesia per rectum. A cathartic of castor oil is given the night preceding the operation and is followed in the morning by soap-suds enemata, one hour apart, or until the return comes back clear. The patient is then allowed to rest for thirty to sixty minutes, when a suppository containing the following substances is inserted: For adults: $\frac{3}{4}$ gr. powdered opium and 15 gr. chlorotone; for children: $\frac{1}{4}$ gr. powdered opium and 5 gr. chlorotone. One hour after the insertion of this suppository, the oil-ether is introduced. It is injected slowly in order to avoid irritation or other untoward effects.

The author gives the histories of two perfect cases illustrative of the application of the method to the human subject. In each the anæsthesia lasted forty-five minutes.

Both clinical and laboratory experimentation with the method is being continued, and reports will be published later.

Caillaud, E.: Prolonged General Anæsthesia with Ethyl Chloride (*L'anesthésie générale prolongée au chlorure d'éthyle*). *Tr. Internat. Cong. Med.*, Lond., 1913, Aug. By Surg., Gynec. & Obst.

Ethyl chloride is very much superior to chloroform or ether for producing general anæsthesia because it is less toxic.

However, ethyl chloride anæsthesia can be produced only by following certain rules that are given by the author, and by using an apparatus that permits mixing at will a definite dosage of ethyl chloride with another anæsthetic and an abundant

supply of air or oxygen. For a minute or two at the beginning of the anæsthesia a few drops of chloroform should be given with the ethyl chloride. After that the ethyl chloride should be continued alone. The author reports five hundred and sixty-eight cases of anæsthesia given with this apparatus, four hundred and fifty-three of which were prolonged anæsthesias for various major operations (stomach, liver, brain, gynecological, etc.). Not a single accident occurred. Anæsthesia takes place rapidly — in one or two minutes. The results are excellent because the organism is submitted to a minimum of intoxication.

Schlimpert: Sacral Anæsthesia (Sakralanæsthesie).

Deutsche Gesellsch. f. Gynäk., Halle, 1913, May.

By Zentralbl. f. d. ges. Gynäk. u. Geburtsh. s. d. Grenzgeb.

The results from low anæsthesias in 114 cases were perfect in 54.4 per cent. In 21 per cent inhalation narcosis was resorted to on account of the long duration of the operations. In 13.2 per cent a certain amount of ether or chloroform had to be used from the beginning. In 11.4 per cent the anæsthesia was absolutely negative.

In 342 cases of high anæsthesias the results were perfect in 46.5 per cent. Ether or chloroform had to be given on account of prolonged operation in 21.3 per cent. In 25.6 per cent the anæsthesia was incomplete, and in 5.6 per cent, negative. The only disturbing complication was a blanching of the face which lasted two or three hours and was associated with a decrease in the blood pressure. The chief advantage was the absence of late complications, especially headaches.

The indications for the different forms of anæsthesia are as follows: The low form of sacral anæsthesia should be used for low operations; chloroform and ether for high operations of short duration, complicated appendicectomies; lumbar anæsthesia for high operations in women with weak hearts and for very fat women; and high sacral anæsthesia for all other cases.

Tuffier, T.: New Methods in Spinal Analgesia.

Tr. Internat. Cong. Med., Lond., 1913, Aug.

By Surg., Gynec. & Obst.

Extradural anæsthesia, which was given up for a time, has been resumed. Injection is made into the sacro-coccygeal orifice, the needle being introduced parallel with the axis of the canal, which generally makes an angle of 45° with the surface of the body. Stovaine and later novocaine have been used. Schlimpert gives, along with the latter, veronal scopolamine-narcophine, scopolamine-pantopon, or scopolamine-morphine to produce amnesia. The anæsthesia lasts three quarters of an hour with the low injection, and from a half to three quarters of an hour with the high injection. The accidents occurring as a result of its use are not grave. The technique is long and complicated and the results uncertain.

Intradural injections are either inferior sub-

medullary or superior (Jonnesco), between the first and second dorsal, and, though seemingly dangerous, have given satisfactory statistics. At first cocaine was used, then stovaine, then tropacocaine, and finally novocaine. The latter is now used by most operators who practice spinal anæsthesia. All of these anæsthetics are today used in combination with various substances.

Jonnesco uses strychnine with stovaine to avoid the accidents attributed to the latter. The mortality varies in different sets of statistics. The causes of death are often unknown. Spinal anæsthesia is contra-indicated in very emotional subjects, in infants, syphilitics, those suffering from medullary affections, and in operations which extend beyond the umbilicus.

Le Filliatre: General Analgesia by Cocaine Anæsthesia of the Lumbo-Sacral Routes (Analgesia général par rachicocainisation). *Tr. Internat. Cong. Med., Lond., 1913, Aug.*

By Surg., Gynec. & Obst.

Le Filliatre of Paris two years ago succeeded in obtaining a constant analgesia not only of the trunk and the upper limbs but also of the head and neck by giving the injection always at the level of the first sacral vertebra after having first evacuated a sufficient amount of the cephalorhachidian fluid. He injects 2 ccm. of a solution of cocaine sterilized at 150° C., freshly prepared, and under the skin of the patient he injects 2 milligrams of strychnine and 5 centigrams of sparteine. At the end of from ten to fifteen minutes a total anæsthesia of the head and the neck is obtained.

The duration of the anæsthesia varies from a half-hour to an hour for the head and the neck and from a half-hour to three hours for the subumbilical region.

Since 1909 the author has produced two hundred and forty-eight analgesias of the subumbilical region, twenty-eight of which were for surgery of the neck and head.

In thirteen years he has produced two thousand, eight hundred and thirty-seven subumbilical or superumbilical analgesias many of which were on the same subject, and he has never noted the least accident either immediate or late.

Lumbar puncture made at the end of twenty-four hours shows that the cephalorhachidian liquid is normal.

Brunner, F.: Paralysis of the Phrenic Nerve after Plexus Anæsthesia (Zur Frage der Phrenicuslähmung nach Plexusanæsthesie). *Zentralbl. f. Chir., 1913, xl, 1104.* By Zentralbl. f. d. ges. Chir. u. i. Grenzgeb.

The author reports two cases with a picture similar to that recently observed in plexus anæsthesia, but without a preceding plexus anæsthesia. In both cases a goiter operation was performed.

The first case was that of a 21-year-old man whose appendix and left lobe of the thyroid were resected simultaneously under chloroform narcosis. Several

hours after the operation the patient complained of severe dyspnoea "as if there were a spasm of the diaphragm." The pulse was 128. There was polypnoea and pain in the abdominal wound. When the dressings were changed no hæmorrhage was found in the wound of the neck. In the morning normal breathing was resumed again.

The second case was a bilateral resection performed for Basedow's disease, with bilateral anæsthesia according to Braun. Four hours after the operation the patient complained of difficulty in breathing and pain in the left chest. Two nights later there was orthopnoea, jerky, cog-wheel expiration, and pain below the left shoulder blade. On the fourth day the X-ray showed a high-standing diaphragm on the right side (2 cm. higher) and free motion on both sides. On the sixth day the respiratory difficulty and pain had disappeared.

The author is of the opinion that an injury irritation of the pleura was present, caused possibly by a hæmorrhage extending along the pleura. This explains the free interval. He has never before observed this in 900 goiter operations. Paralysis of the phrenic nerve, or irritation, seems to him improbable for many reasons. Sauerbruch does not report any such phenomena in repeated phrenicotomies; according to Kulenkampff the phrenic nerve does not carry any fibers sensitive to pain; Oehlecker believes that the pain must have some other source; according to Hirschler, long-continuing paralysis and pains are due to nerve injuries, and not to the effect of the novocaine suprarenin solutions.

KULENKAMPFF.

Gembicki: "Narcosia," a New Hamamelis Local Anæsthetic ("Narcosia," ein neues Hamamel-Lokal-Anæstheticum). *Deutsche zahnärztl. Wchnschr.*, 1913, xvi, 521.

By Zentralbl. f. d. ges. Chir. u. i. Grenzgeb.

The author has attempted to reduce the toxicity of cocaine by adding hamamelis extract. In this way he has succeeded in diminishing the cocaine content to 0.75 per cent and obtaining the same effect as that given by a 1 per cent cocaine solution.

The mixture he calls "narcosia." In contrast to suprarenal preparations, the hamamelis extract has an anæsthetizing power, is not a toxic body, and does not produce muscular contraction. It has a tonic action on the heart and accelerates the healing of wounds. The author has used this mixture in about 1,000 cases with good results.

HERDA.

SURGICAL INSTRUMENTS AND APPARATUS

Connell, K: An Apparatus—Anæsthetometer—for Measuring and Mixing Anæsthetics and Other Vapors and Gases. *Surg., Gynec. & Obst.*, 1913, xvii, 245
By Surg., Gynec. & Obst.

The author describes an apparatus developed from a commercial gas meter which measures and records the passage of air and other gases, mixes two or more gases automatically in the desired proportion, and also feeds air and volatile liquid automatically into a common mixing chamber.

Delivery of these accurate mixtures to the patient may be effected by a closed face mask. After surgical anæsthesia has been once established, however, the author prefers to deliver by insufflation. He describes his method of pharyngeal insufflation, which consists of insufflation into the lower pharynx per moment of the entire bulk needed for inspiration of an accurately prepared anæsthetic mixture. For routine delivery this method is preferred to intratracheal insufflation.

The percentages of ether vapor in air required by man have been established by this apparatus as follows: The most advantageous delivery curve rises during primary anæsthesia to 35 or 45 per cent by weight of ether vapor to air at sea level. With the beginning of relaxation the curve falls to 26 per cent, and within a few minutes to 21 per cent at which level it remains for five or ten minutes. The percentage is then gradually lowered to 15 per cent by the end of 40 minutes. This percentage has been found to establish the proper anæsthetic tension for the indefinite continuance of full surgical anæsthesia. Lower percentages are used only where light anæsthesia is desired. The one variable factor is the length of time and the difficulty in saturating a particular individual to this uniform anæsthetic tension of 48 millimeters, an equivalent of 15 per cent ether vapor pressure in the alveolar air. The time varies from 5 minutes, in an infant, up to 40 minutes, in a robust alcoholic.

The author discusses the utility of heating anæsthetic mixtures, and concludes that artificial heat is of importance only to effect accurate vaporization, since the actual loss of body heat through warming respired gases is negligible.

Accuracy of dosage and automatic delivery have increased the safety and efficiency of ether administration, and decreased the shock of operative procedure and the sequelæ of ether anæsthesia.

SURGERY OF THE HEAD AND NECK

HEAD

Kahn, L. M.: Congenital Bilateral Fistula of the Lower Lip. *Am. J. M. Sc.*, 1913, cxlvi, 223.

By Surg., Gynec. & Obst.

The author reports twenty-two cases from the literature and one of his own. The latter is a patient

three years of age who shows no other facial or congenital deformity and is perfectly healthy. The family history is negative. The fistulæ open on either side of the median line of the lip. The slightly oval opening admits a small probe which may be passed downward and inward toward the median line and inserted into fluid pockets just

beneath the mucous membrane on the inner surface of the lip. The fistulae are about 1.5 cm. in length. They do not communicate with each other but are separated by a thin fibrous partition. The openings are filled with a glairy transparent secretion.

In reviewing the cases reported, Kahn finds that the condition is usually accompanied by other congenital deformities such as cleft palate and hare-lip; also that it frequently occurs in two or more members of the same family. Huber offers the following explanation: "On either side the well-known median notch seen to persist sometime during intra-uterine life after fusion of the two halves of the lower lip has been completed, it is not unusual to detect a slight secondary notching on either side. This becomes deeper, its deepest portion becoming gradually buried until a short tubular tract lined with mucosa is formed." The treatment indicated is excision.

H. A. PORTS.

Coleman, F.: The Treatment of Fractures of the Mandible. *Tr. Internat. Cong. Med.*, Lond., 1913, Aug. By Surg., Gynec. & Obst.

Before considering the treatment of fractures of the mandible, a few remarks on their etiology, position, and character will serve as an aid in determining the method of treatment to employ.

Fractures of the mandible are almost invariably the result of direct violence. The seat of the fracture, however, is not infrequently on the side opposite to that which sustained the injury.

Fracture of the mandible occurs rarely when the teeth are in occlusion, as under these circumstances the maxilla and mandible become for all practical purposes one bone, so that the brunt of the blow is transmitted through the condyle of the jaw to the glenoid fossa, producing concussion of the brain and in some cases a fracture of the base of the skull.

The signs and symptoms of fracture of the jaw do not fall within the scope of this paper, but the author wishes to mention a sign that has so far escaped attention or has not been appreciated.

The sign in question is produced by an effusion of blood into the tissues of the floor of the mouth, and gives rise to a very characteristic appearance of its mucous membrane, which becomes raised, forming a bluish, tense swelling under the front part of the tongue. The sublingual fold lying between the tongue and the mandible is chiefly involved in this effusion, as the mucous membrane elsewhere is too firmly bound down to bulge in this manner.

This sign alone will serve to differentiate an external bruise from an injury that has produced in addition a disunion of the jaw, for it is difficult to understand, from an anatomical point of view, how an effusion of blood can take place into this space bounded externally by the deep cervical fascia and the body of the mandible unless a lesion of one of these structures has occurred. We can disregard the deep cervical fascia, which is not a structure readily torn, and, therefore, surmise that the breach has involved the body of the mandible.

The author has found this sign to be present almost invariably and to form as conclusive evidence of a fracture of the mandible as an effusion of blood into the orbital cellular tissue is evidence of a fractured base.

In young children it is sometimes impossible to make a diagnosis immediately after the injury, except by the use of skiagraphy or by the aid of an anæsthetic, nor is it strictly necessary. The parts are so much inflamed and swollen with effused blood that even if a fracture were detected, it would be harmful as well as painful to apply pressure in any form over the swollen tissues. After a few days most of the blood and exuded lymph will have become absorbed, the inflammation will have subsided, so that the mouth can be opened to a greater extent and a more thorough examination can be made with a view to diagnosis and subsequent treatment. Even if wiring of the bony fragments be contemplated, this operation will be rendered far easier and less risk of sepsis will be incurred if it be delayed until absorption of some of the inflammatory exudation has taken place.

Fractures in children can usually be treated satisfactorily with metal, gutta-percha, or poroplastic splints moulded to the outside of the jaw. In adults if there be but little tendency to displacement of the fragments, the same methods will suffice.

Out of some 50 cases of fracture of the jaw that have passed through the author's hands for treatment, he has only once been obliged to apply an internal splint for a child.

An external splint will allow slight movement at the condyle of the jaw, but if the splint be carefully moulded, very little movement will take place in its continuity.

The chief value of external splints is to keep the jaw at rest when there is not much tendency to displacement, and to act as a danger signal in protecting the patient from further injury. The four-tailed bandage serves practically only the latter function.

Wiring the teeth together, although a method that dates back to the time of Hippocrates, should rarely be used for retaining complete fractures of the mandible in position, and never if other methods be available. The teeth on either side of a fracture, if not already loose and tender, will rapidly become so when this unnatural strain is put upon them.

The principle of all mechanical appliances in the treatment of fractures of the jaw is to retain the fragments in position with a minimum of discomfort to the patient and with the least interference to the function of the part.

The internal splints employed for fracture of the mandible conform largely to three types; viz.,

1. Those which utilize the teeth as their abutments in controlling the fragments; e.g., Hammond splint, Tomes splint.

2. Those which utilize the teeth and body of the jaw as their abutments in controlling the fragments; e.g., Kingsley splint, Ackland splint.

3. Those which utilize the teeth of the opposite jaw (i.e., maxilla) as their abutments in controlling the fragments; e.g., Gunning splint, Hern splint.

Some of the splints used combine two or more of these principles or are reinforced by other means.

Before any form of splint is adapted to the jaw, some attempt should be made to get the mouth into a clean condition.

Even if the mouth be clean and healthy at the time of the fracture, it rarely remains so subsequently, owing to the impairment of mastication and deglutition that result. Apart from this, there is a natural disinclination on the part of the patient to carry out the ordinary routine of cleanliness on account of the discomfort it entails, nor can this be performed satisfactorily by the nurse or surgeon in charge.

Moulds of the jaws are obtained from wax, gutta-percha, or plaster pressed over the teeth, the material used being retained in a cup or tray. A counterpart in plaster of Paris is made from the mould. There is no need to reduce the fragments while taking the impression, but the jaw should be carefully steadied. The plaster model is sawn through in the line of fracture, should there be any displacement, and the splint fitted to the corrected model. Models of both jaws must be obtained when the splint is to take its bearings on both these parts, or if the articulation of the broken jaw requires some rectification.

If a metal plate or frame is to be fitted to the teeth, dies must be obtained.

Splints made to fit the teeth, gums, or both of these parts, should be made slightly loose when there is difficulty in reducing the fragments, for, although the deformity may be readily corrected on a model, it may be far less easily rectified in the mouth, so that allowance must be made for the difficulties that may be encountered in restoring the parts to their correct alignment.

When the splint is ready for insertion, the fragments are reduced; an anæsthetic is sometimes useful at this stage.

Splints are usually retained in the mouth for six to eight weeks. Even if the fragments have not come into accurate apposition, and a slight gap exists between opposing teeth in the region of the fracture, this will be almost entirely effaced within six months to a year, owing to the elongating of the teeth until resistance from occlusion is offered.

Some two or three years ago the author devised a jaw-clamp that he hoped might be of great service in fixing the fragments of a broken jaw, and obviate the necessity of making a special splint for each patient.

The principle of the clamp consisted of a strong steel spring, which could be opened to enclose the alveolus, and when released embedded itself in the bone by means of its projecting claws.

The splint was applied as follows:

The patient was placed under an anæsthetic, the fragments of the jaw were reduced, the clamp was

opened (with a special instrument) and forced over the jaw in the region of the fracture and then released; thus the clamp was left embedded on each side of the fracture.

The sharp projections or claws at the extremities of the limbs of the clamp readily penetrated the mucous membrane, but did not sufficiently penetrate the bone to fix the fragments securely. The ease with which the clamp could be inserted and removed, its cleanliness, and the ready access to the site of the fracture that it allowed, were advantages which appealed strongly in its favor. Moreover, the clamp was adaptable whether teeth were present or not, and could be used over and over again.

The author has employed the clamp only in one case, and although the result was excellent, he is unable to say how much this result was due to the use of the clamp, as in most cases of fracture of the jaw the result is satisfactory provided there is no great tendency to displacement of the fragments.

The clamp was left on for six weeks or more, during which time the patient experienced but little discomfort.

The principle of the clamp seems worthy of attention, and if only some means can be devised by which the hard tissues can be penetrated as well as the soft, the clamp would form a useful means of retaining fragments of the jaw in apposition.

Wiring the fragments together is not a method of treatment often required for fractures of the mandible.

If a Hammond or a metal-cap splint has been utilized, semi-solid food may be given within a day or two, and after two or three weeks this may be gradually replaced by, or incorporated with, finely divided solid food.

Those splints that fix the jaws to each other, necessitate the maintenance of a fluid diet until the splint is removed. The spout of the feeding cup should be fitted with an India rubber tube which can be passed into the space afforded by the splint.

The opening of an abscess may be required during the treatment of a fractured jaw. This is usually only a temporary expedient, as the abscess is usually due to necrosed bone, and until this is removed or has become exfoliated, the cause of the abscess remains. Sequestra of the body of the mandible are very slow in separating, and a sinus may persist for a year or more.

In neglected cases the tissues around the jaw may be riddled with abscesses discharging through puckered sinuses.

Ankylosis of the temporo-mandibular joint is a frequent sequel of fracture of the condyle.

Failure of bony union is uncommon. Gurlt met with only two instances of failure of union in his 143 recorded cases, and both of these were subsequently cured by operation.

The chief causes of failure to unite are want of rest of the fragments and necrosis, especially if the latter be extensive so that the ends of the living bone are widely separated.

Von Láng, K.: Suppurations of the Frontal Sinuses (Über abscedierende Stirnhöhleenerungen).
Beitr. z. klin. Chir., 1913, lxxxiv, 226.

By Zentralbl. f. d. ges. Chir. u. i. Grenzgeb.

Suppurations in the frontal sinuses originate exclusively in the nose. The most frequent cause is coryza and influenza. Much more rarely the inflammation is due to neighboring syphilitic or tuberculosis processes or trauma. Both acute and chronic disease is a source of constant danger because the infection may spread through congenital clefts in the bone or by way of the veins and lymph vessels, but principally through necrosis of the bone. The intactness of the bony wall is chiefly responsible for the local character of the affection. The thin lower wall is most frequently destroyed. The consequences are abscesses in the orbit, which in the most favorable cases perforate the upper eyelid, but frequently produce extensive orbital phlegmons. Necrosis of the anterior wall of the frontal sinus is less dangerous, as the pus can be easily reached under the skin of the forehead. Most rarely does the disease affect the posterior wall, in which case it leads as a rule to intra-cranial complications. In one or two days, the bone may be destroyed by an acute virulent inflammation and fatal meningitis may develop. Extradural as well as brain abscesses have also been observed. Meningitis serosa is rare and more favorable for the prognosis.

Diagnosis of frontal sinus suppurations with abscess formations is usually easy, especially if the presence of pus can be determined in the middle nasal passage. While uncomplicated frontal sinus suppurations with abscess formations are successfully treated endonasally, the abscess-producing forms are naturally attacked from the outside. Besides the incision of the abscess the frontal sinus must be opened widely. Kuhnt, Killian, and Riedel have pointed out the most useful methods. Their choice depends upon which of the walls is diseased. If the cranial contents are affected, purely surgical principles of treatment are employed. Onodi gives suitable directions for puncturing the frontal lobes. Thrombosis of the longitudinal sinus also must not be overlooked.

PAETZOLD.

Nimier, H., and Nimier, A.: On the Treatment of Fractures of the Petrous Portion of the Temporal Bone (Sur le traitement des fractures du rocher). *Rev. de chir.*, 1913, xlviii, 22.

By Journal de Chirurgie.

Admitting that non-infection of the tympanic cavity is of great importance in a majority of fractures of the petrous portion of the temporal bone, the authors, on the basis of the statistics of Phelps and Valentin, do not advise surgical interference in these fractures. In most cases drying of the auditory canal and the application of an absorbant dressing to the external ear is sufficient. When there is suppuration in the middle ear, either before or after the fracture, Nimier and Nimier believe that it should be the rule not to operate. Neither otor-

rhagia or escape of cerebro-spinal fluid are, according to the authors, *per se*, indications for operation. On the other hand, if an infection is present as confirmed by spinal puncture, then a decompression with permanent drainage is indicated. The subtemporal trephining is preferred to other craniectomies.

Decompression is indicated in cases of extradural hæmatoma in these fractures, especially if the mastoid ecchymosis comes at the location of the fissure. The authors prefer to the submastoid route, the transmastoid with exposure of the lateral sinus. If the hæmatoma is intradural (supposing that the localization can be made clinically) the submastoid route is preferred.

In case there is a bone disease, the authors, without admitting the absolute necessity of operation, recommend enlarging the opening in the tympanum. If there are concomitant encephalic troubles, they advise an operation with respect to the site of the bone disease rather than a preventive operation.

If the infection leads to a serous meningitis or a meningism, operation on the ear generally suffices, as is the case in more severe infections, where, however, a more radical operation including the cerebellar fossa and the submastoid region is necessary.

J. OKINCZYC.

Manges, W. F.: Findings in Obscure Head Lesions. *Tr. Am. Röntg. Ray Soc.*, Boston, 1913, Oct.

By Surg., Gynec. & Obst.

The subject is treated under two heads: (1) The findings in the skull bones; (2) the findings in the brain and its processes. The findings in diseases of the accessory sinuses and mastoids, and diseases and irregularity of the teeth and facial bones are not included.

Various subjects discussed are the findings in the skull bones due to external and internal influences, the immediate results of injury; the nature and extent of fracture, etc.; remote results; overlooked fractures; the organization of blood clots; osteomyelitis; periostitis; and factors tending toward malignancy, gumma, etc. Abscess of the brain is most frequently due to infection from skull bones or their processes; hence roentgenographs will be of decided value in showing the source of infection and help to differentiate it from other conditions. Even the more superficial abscesses may be localized by this means. Atrophy of the inner table of the skull due to pressure seems to show on the roentgenographs the location of tumors, cysts, etc., when they are superficial. General thinning of the skull bones with depressions corresponding to the brain convolutions occurs when there is internal hydrocephalus from any cause. In external hydrocephalus the bones may be thin but the convolution depressions are absent. The skull sutures are apt to be separated in both. A certain number of brain tumors are dense enough to cast diagnostic shadows. Nearly all tumors at the base of the brain will produce internal hydrocephalus. Reference is made

to the article by Bailey and Jelliffe on pineal tumors, and to abstracts of all reported cases (*Arch. Int. Med.*, 1911, viii, 851). Internal hydrocephalus was noted in nearly every case. This is clearly shown on roentgenographs.

The numerous investigations made of pituitary conditions are referred to only briefly. In twenty such recent cases with obscure head symptoms the author has found shadows of calcareous bodies in the region of the pineal gland. One case was an acromegalic, two had exophthalmic goiter, and several were epileptics. Nearly all had severe headache at times, and practically all had some irregularity of the sella turcica or clinoids.

Rasumowsky, W. J.: The Question of Surgical Treatment of Cortical, Traumatic or Non-Traumatic, Epilepsy (Zur Frage der chirurgischen Behandlung der corticalen, traumatischen und nicht traumatischen, Epilepsie). *Arch. f. klin. Chir.*, 1913, ci, 1075. By Zentralbl. f. d. ges. Chir. u. i. Grenzgeb.

According to the latest theories in regard to the nature of epilepsy, a strict differentiation between organic and genuine epilepsy is not permissible. In the majority of all of the cases of genuine epilepsy examined systematically, local affections have been found. Other forms begin as Jackson's spasms and assume the genuine character gradually. Local affections lead in time to permanent changes of a diffuse character.

Of the local diseases, the cortical and subcortical affections are especially adapted to surgical treatment. In some cases, however, the excision of the epileptogenous cortical centers has resulted in cure when the local organic changes were remote. In traumatic epilepsy changes caused by the trauma are found in the brain or in the covering layers. In traumatic Jacksonian epilepsy also without visible changes the removal of the centers is indicated. If general epilepsy without localized symptoms occurs after trauma the formation of a valve is indicated.

The author has operated on fourteen cases of non-traumatic Jacksonian epilepsy. One of these patients died at the end of nine months from purulent ependymitis of the ventricles of the brain. In more than half of the cases of epilepsy the results were good and only three or four were negative. In nearly every case bipolar stimulation was used to find the epileptogenous centers. In some cases this caused a pronounced epileptic spasm; in some, only the beginning of a spasm; and in others, only simple physiological contractions. After the center was found, the cortex was amputated in layers from seven to ten millimeters in thickness with a sharp knife or spoon until the irritation caused no or only slight epileptic contractions. The center was extirpated also in cases where no epileptic cramps could be elicited. Sometimes paralysis occurred but in every case it soon disappeared. A disturbance of the stereognostic sense lasts longer, but anaesthesia disappears quickly. In three cases of Koshewnikow's epilepsy an operation was per-

formed with good results, the arm center being excised in each instance. WORTMANN.

Rehn, E.: Autoplastic Fat Transplantation for Defects in the Dura and the Brain (Die Verwendung der autoplastischen Fetttransplantationen bei Dura- und Hirndefekten). *Arch. f. klin. Chir.*, 1913, ci, 962.

By Zentralbl. f. d. ges. Chir. u. i. Grenzgeb.

With the introduction of dura plasty, the treatment of traumatic epilepsy has reached a new and successful stage. The result obtained by the author with autoplastic fat transplantation has been very favorable. In order to judge the method, a careful selection of suitable cases of purely typical partial and general traumatic epilepsy is necessary. A case can be pronounced cured only on the basis of an observation made from three to five years after the operation.

The results of dura plasty with transplantation of periosteum, peritoneum, and fascia also are discussed. The observed change of the transplanted fascia and pieces of peritoneum into fatty tissue the author considers a very useful sign of adaptation and an essential factor for the cure of traumatic epilepsy. In experiments with autoplastic transplantation of fat in dogs, he obtained a reactionless cure without the least disturbance of the central nervous system. The greater portion of the fatty tissue preserved all of its constituents unchanged and became the permanent possession of the part of the body into which it was put. The histological changes were illustrated with drawings. The transplantation formed a basal plate of connective tissue which completely covered the defect in the dura. Becoming more and more tense, though retaining its fine character, it formed a full substitute for the dura. Adhesions to the soft cerebral membrane could not be avoided, but as they formed only delicate connective-tissue strands they could always be easily loosened. On the basis of a successful case, the author recommends the transplantation of fat also for the purpose of plugging a defect in the ventricle. DE AHNA.

Luckett W. H.: Air in the Ventricles of the Brain Following a Fracture of the Skull; Report of a Case. *Surg., Gynec. & Obst.*, 1913, xvii, 237.

By Surg., Gynec. & Obst.

The author reports a case of a machinist who was struck by a trolley car, sustaining a fracture of the frontal bone and skull. Twelve days later he was apparently normal as far as his mental state was concerned. A week after this, he had periods of mental confusion and melancholy; otherwise he was normal except for increased knee jerks. The leucocyte count was 15,900. The eye grounds showed a bilateral optic neuritis. The condition was diagnosed as due to intracranial pressure caused probably by an abscess.

A series of X-ray plates showed that the ventricles were enormously dilated with either air or gas. The

ventricle was punctured through a right-sided subtemporal opening. On exposure, the dura did not bulge and was not particularly tense. No fluid escaped when the dura and pia were incised. A slight meningitis was noted. A needle was passed into the anterior horn of the lateral ventricle, and the removal of the trocar was followed by spurts of air. Eight cubic centimeters of clear cerebrospinal fluid also escaped. Owing to the presence of the air in the ventricles, a small piece of twisted rubber tissue was inserted into the cisterna magna through a suboccipital opening. Considerable clear fluid mixed with air passed from here also. The patient did well until the fourth day after operation when his temperature suddenly rose to 107° and he died.

At autopsy, air was found in the ventricles. There was a lacerated wound of the base of the right frontal lobe beneath the anterior horn and over the fracture in the orbital plate which communicated with the frontal sinus. It was subsequently learned that the air was probably forced up into the ventricles through the fracture in the frontal sinus during an attack of sneezing.

EDWARD L. CORNELL.

Bruns: The Treatment of Tumors of the Brain and the Indications for Operation (Behandlung der Gehirntumoren und die Indikationen für deren Operation). *Tr. Internat. Cong. Med.*, Lond., 1913, Aug.

By Surg., Gynec. & Obst.

Operative treatment of tumors of the brain are of two kinds: radical operations with extirpation of the tumors, and palliative operations for the relief of the brain. The latter are usually primary, but if for any reason the radical operation is not successful, they may be secondary. The indications for the radical operation and the prognosis of this operation depend upon three things:

1. The nature of the tumor. The most favorable are the sharply circumscribed tumors and especially those that are extracerebral. Unfortunately, clinical differentiation between the common infiltrating gliomata and the sharply circumscribed sarcomata, etc., is still very difficult.

2. The possibility of making a positive general and local diagnosis. The general diagnosis may be difficult on account of abscess, hydrocephalus, and the so-called pseudo-tumors. Local diagnosis is often impossible in cases of tumors in the right temporal and frontal lobes, and is difficult in cases of tumors in the semioval centrum and the corpus callosum.

3. The accessibility of the tumors. Tumors of the brain in the third ventricle are inaccessible to operative treatment as are also many of those in the medulla of the hemispheres. All others are accessible to surgical treatment with varying degrees of danger attending the operation. Primary palliative operations are indicated in cases in which, though there is no local diagnosis, the general diagnosis is positive and the general symptoms are very severe. They are indicated especially if the vision becomes so impaired that blindness is threatened.

Leri, A.: Acromegaly (Akromegalie). *Handb. d. Neurol.*, 1913, iv, 283.

By Zentralbl. f. d. ges. Chir. u. i. Grenzgeb.

The symptoms and course of the disease are described in detail. The diagnosis, which in outspoken cases rests on the characteristic physical findings, is fully discussed. In cases which are not so evident the X-ray may be used to confirm the diagnosis. The sella turcica is markedly enlarged, the skull is not of uniform thickness, and the various sinuses are distinctly widened. The eminences posterior to the lambdoid suture are much more prominent than normal. X-ray pictures are especially useful in the beginning of the disease to prevent confusing it with those conditions which do not, as a rule, involve the bones of the skull as well as those of the trunk and the extremities, but are confined either to one or the other; i.e., Paget's disease, rachitis, myxœdema, leontiasis ossea of Virchow, oxycephaly, and the hypertrophic pneumatic osteoarthropathy of Marie. The clinical picture of these various diseases is outlined sufficiently to bring out the differential diagnosis quite clearly. The objectively demonstrated changes in the hypophysis as an etiological factor conclude the first part. In the chapter on the pathogenesis and pathological physiology the author discusses various hypotheses. He is of the opinion that the cause of acromegaly is to be found in a lesion of the pituitary gland, and that back of it lies a dystrophic condition of the gland. The fact that tumors of the hypophysis occur without producing acromegaly does not affect this theory, since it has been shown experimentally that microscopically small portions of glandular tissue are sufficient for physiological function.

Whether the symptoms are produced by a hyper- or a hypo-secretion is hard to determine as the arguments for and against are not at all conclusive. Of therapeutic measures which are applicable, hypophyseal organotherapy is suggested if it can be proved that a hyposecretion is the cause of the disturbance. The results with this method have been unsatisfactory. Radiotherapy is capable of destroying hypophyseal tumors and seems to give the best results if applied in the form of the "crossed rays." Bécclère applies the rays to the hypophysis through the mouth and over the forehead and parietal regions. The earliest possible treatment is credited with the best results. If both of these lines of treatment prove unsuccessful, surgical procedures are indicated. Hirsch operates through the nasal cavity. After resecting the septum and the upper muscles he enters the sphenoid fossa. Of twenty-six patients operated upon by this method, three died and fifteen showed decided improvement. Von Schloffer and von Eiselsberg used the nasal route, the former by separating the nose from above downward, and the latter by making the flap from within outwards. By this method the ethmoidal cells are removed, the sphenoidal fossa opened; and its posterior wall removed. The results were gratifying. The severe headache subsided, the

visual disturbances were benefited, and the osseous deformities were checked. Three cases that prior to operation had acute coryza died of meningitis. Acute nasal inflammations, therefore, are a contra-indication to operation.

COSTE.

Stendell, W.: *The Comparative Anatomy and Histology of the Hypophysis Cerebri* (Zur vergleichenden Anatomie und Histologie der Hypophysis cerebri) *Arch. f. microscop. Anat.*, 1913, lxxxiii, 289.

By Zentralbl. f. d. ges. Chir. u. i. Grenzgeb.

The author has examined twelve species of Selachii, and the camel and the elephant and has studied the functional relations of the parts of the hypophysis in the production of its secretion. In spite of their common origin from the epithelium of the primitive buccal cavity, the anterior lobe and the pars intermedia must be regarded as two different ductless glands. The pars intermedia, which is poor in blood vessels, is closely connected in all animals with the posterior lobe, which is abundantly provided with blood and lymph vessels, and which, on account of its purely neuroglial structure, must be regarded as a conductor for the secretion of the pars intermedia rather than a secreting gland.

In some species of animals definite "pathways" from the secreting glands of the pars intermedia to the posterior lobe can be demonstrated. Since colloid is found only in old individuals in both the anterior lobe and the pars intermedia, it must be regarded not as a normal secretion but as an evidence of degenerative processes. However, it may be taken as an indicator of the course followed by the normal secretion which cannot be demonstrated. While the pars intermedia is most highly developed in the lower mammals, and steadily decreases in size as we rise in the scale, in man the prehypophysis is most highly developed. Throughout the whole animal kingdom it is connected only slightly with the pars intermedia and the posterior lobe, frequently by a connective tissue septum or a small pedicle (Sauropsida). In the amphibians the two parts lie side by side without any organic connection, and in mammals they are separated by the hypophyseal recess. Therefore it is probable that the secretion of the anterior lobe is not conducted through the posterior lobe but is discharged directly into the blood.

The glandular cells are located on the epithelium of the blood vessels; in the vessels a coagulated secretion can often be demonstrated. The author agrees with Benda and Creutzfeld as to the identity of the three kinds of cells of the anterior lobe, in that he regards them as only different stages in the development of one kind of cell. In the lower animal orders there are frequently masses of secretion lying between the vessel walls and cells.

As the result of his experiments the author concludes that the theory that the parts of the hypophysis have different internal secretions, is confirmed by their morphological character.

Austoni, A.: *Experimental Compression of the Hypophysis* (Sulla compressione artificiale del l'ipofisi). *Polichin.*, Roma, sez. chir., 1913, xx, 159.

By Zentralbl. f. d. ges. Chir. u. i. Grenzgeb.

The author claims priority over Chiasserini in experimental investigations on the hypophysis in situ, since in his article on hypophysectomy (Padova, Edit. Soc. Coop. Tip., 1912) he gave a new method for studying the function of the gland. In order to overcome the severe traumatism which occurs during the removal of a gland for the purpose of eliminating its function, the author introduced a laminaria bougie close to the hypophysis for the purpose of slowly compressing it in situ. By means of this artificial tumor he wished to determine conclusively whether the explanation of the hypophysis symptoms (acromegaly, dystrophia, adiposogenitalis, glycosuria, somnolence, cachexia, hypophyseopriva) on the basis of the mechanical action of the tumor is correct. The object was not so much to clear up the syndrome of acromegaly as to decide whether it was the pressure on the pituitary body or upon the neighboring parts of the base of the brain that called forth the dystrophia hypophysialis.

Dogs were used for the experiments, but monkeys are better adapted. All of the animals were young and fully developed. The control dog was of the same sex, race, and age as the other. In the one the dry, sterilized laminaria bougie was introduced between the hypophysis and the base of the brain, while in the control the parts were exposed in the same way but the bougie was not introduced. In looking for the hypophysis the author used a new procedure for craniectomy temporosphenoidalis similar to the Hartley-Krause method for resecting the gasserian ganglion. On the right side of the head a horseshoe-shaped flap, including skin, temporal muscle, and periosteum, was made. This was turned upwards. By opening the mouth the coronoid process was drawn downward, the upper part of the pterygoid muscle was freed, and in this way the anterior inferior part of the parietal, the squamous portion of the temporal, and the greater wing of the sphenoid bones were laid bare. All of these parts were removed to the crista sphenotemporalis, and thus the brain could be raised so as to expose the hypophysis. The author recommends the same procedure for the operation on the human being. The method is preferable to Paulesco's, for in laying the scalp flap downward one has less room below and must do more trephining, besides being obliged to raise the brain much higher. It is also better than the modification of Chiasserini in which the flap is not resected and the temporal muscle is cut across.

STREITZLER.

Preysing: *A New Method of Operating upon the Hypophysis* (Beiträge zur Operation der Hypophyse). *Internat. Zentralbl. f. Laryngol., Rhinol. u. verw. Wiss.*, 1913, xxix, 401.

By Zentralbl. f. d. ges. Chir. u. i. Grenzgeb.

Preysing recommends operating on tumors of the hypophysis by resecting the hard palate. This

method is especially valuable for very large tumors, for which the author has used it in four cases. He believes it offers a closer approach to, and a better view of, the field of operation than any procedure that has been used previously.

DENK.

Holmgren, G.: Operations on the Hypophysis by the Nasal Route (Über transnasale Hypophysisoperationen). *Hygiea*, 1913, lxxv, 481.

By Zentralbl. f. d. ges. Chir. u. i. Grenzgeb.

The author gives a very detailed description of a case of tumor of the hypophysis which he observed and operated upon. The patient was a man thirty-four years of age, who had always been well previously. For two years he had had periodical headaches which varied in intensity and were more severe on the right than on the left side. Visual disturbances were first noticed in the left eye and then in the right. After a year there was only partial perception of light on the temporal side of the right eye, and the visual acuity of the left eye had decreased to 2/60. On admission to the hospital the patient could count fingers with the left eye only when they were held immediately in front of the eye. There was temporal hemianopia and the visual field was very much decreased concentrically. The right eye had not changed since the previous examination. On both sides there was marked optic nerve atrophy. Polyuria was marked. Great changes in the X-ray picture. Hirsch's operation was performed. Technically it was easy until the point of incising the dura was reached. The entire roof and posterior wall of the sphenoidal sinuses was simply a mass of soft, red, pulsating tissue pushing forward into the sinuses. The operator could not find any definite tumor so he merely punctured the dura and curetted. The operation lasted for one and one half hours. Iodoform gauze tampons were placed in the nasal cavities. There was no drainage of the sphenoid sinuses. The operation was followed by a transitory rise of temperature and complete blindness for a few days. This the author attributed to the fact that the sphenoid sinuses and the cavities in the tumor had filled up with blood that was not entirely sterile. After a month the patient could count fingers at a distance of one meter from the left eye. The visual field increased on the nasal side. The pupils were not so pale as before the operation. Three weeks later the patient was well, could read the time on his watch, and was able partially to carry on his work of farming.

GIERTZ.

Johnston, G. C.: The Radiology of the Pituitary Body in Epilepsy and Pituitary Disorders. *Tr. Am. Röntg. Ray Soc.*, Boston, 1913, Oct.

By Surg., Gynec. & Obst.

Johnston has made X-ray studies of the pituitary fossa in some eighty cases of epilepsy, which included principally patients who developed epilepsy between the fifteen and thirty-fifth year and did not include patients who showed epileptic attacks as a

part of the symptom-complex attendant upon pituitary struma. He has been struck by the practically constant occurrence in such cases of a marked hypertrophy or hyperostosis of the posterior clinoidal processes which results in an apparent roofing of the fossa with consequent encroachment upon and interference with the posterior lobe of the pituitary.

Attention is called to the work of Cushing, who has shown that posterior lobe hypo-pituitarism will produce epilepsy and believes that this is the probable explanation of the cause of the attacks in the class of patients described. He shows repeated examples of this type of anatomical deviation in this class of cases and states that the feeding of posterior lobe extract to such patients is followed by interesting results.

The author makes no attempt to explain the occurrence of the hyperostosis beyond the statement that syphilis seems to play no part and that in some of the cases the process is apparently active. He makes a plea for the examination of a large number of this class of patients in order that the true percentage showing this condition may be determined. He believes that in some of the cases reported, the gland is so interfered with that its functional activity is hampered and in two of the cases calcareous degeneration of the gland was apparently going on. In many of the cases shown, the shadows of the anterior and clinoidal processes not only meet but decidedly overlap. In his own series of cases this condition was found to be present to a greater or less degree almost invariably.

In order to be of value the examination must be made with strict attention to the planes of the skull so that distortion may be avoided. In the cases shown and described, pituitary tumors were excluded although a number of such cases showing epilepsy as one of the symptoms were classified and described separately.

The epileptics examined were selected by the neurologists, McKennan, Henninger, and Mayer. Cerebropathy, cerebral syphilis, etc., were excluded.

NECK

Nicoll, J. H.: The Avoidance of Unsightly Scar Deformities in the Operative Treatment of Cervical Lymphadenitis. *Glasgow M. J.*, 1913, lxxx, 81.

By Surg., Gynec. & Obst.

Reference is made by the author to the changed attitude that the profession has taken toward the treatment of tuberculous joints. A few years ago the attempt was made to remove all of the tuberculous tissue in connection with a tuberculous joint. Nowadays much more conservative measures are followed and more dependence is placed upon the patient's ability to overcome the infection when a slight stimulus is given either through the removal of part of the tuberculous material, the injection of some stimulating drug into the region, or a combination of both measures. The same change toward

conservatism has been noticed in the treatment of tuberculous lymphadenitis, especially that of the cervical region. The radical operation for the clean removal of all of the diseased glands has, in part at least, given way to a more conservative and less disfiguring measure.

The operations which the author emphasizes especially are Treves' operation and Dollinger's operation.

The Treves operation is performed as follows: A small incision is made, usually in the region of, and parallel to, the clavicle. Through this incision the enlarged glands are tunneled out by the dissecting finger. A small gauze wick is placed in the opening for drainage.

The Dollinger operation is very similar but is intended primarily for operations upon glands in the occipital region. The incision is made in the hair line and the lower flap is turned down so as to expose the underlying glands. The latter are then removed *en masse* as far as possible and the wound closed with a small gauze drain.

J. H. SKILES.

Morestin, M. H.: The Excision of the Groups of Cervical Lymph Glands in Cancers of the Mouth and of the Pharynx (L'évidement des gîtes ganglionnaires cervicaux dans les cancers de la bouche et du pharynx). *J. de chir.*, 1913, x, 657.

By Surg., Gynec. & Obst.

Morestin contends that the doubtful prognosis in cancer of the mouth has been due to the delay in surgical treatment and to too-restricted operations. Cancers of the mouth and pharynx remain strictly local for only a very short time; they extend very rapidly into the lymphatics. On the other hand, they very rarely form distant metastases, and thus can be considered quite favorable for complete eradication of the disease provided the surgeon regards not only the initial lesion, but also the entire lymphatic apparatus which drains the region as a cancer that should be removed.

All cancers of the buccal mucous membrane, the lip, the cheek, the floor of the mouth, the tongue, the pharynx, the nasal fossæ, and the jaws, all cancers originating in the skin which have infiltrated the depths, and all cancers of the parotid demand absolutely the extirpation of the corresponding groups of cervical glands. This extirpation may be uni- or bilateral; it can be done at one sitting with extirpation of the primary growth, or may precede or follow the latter. The operative technique varies somewhat according to the site of the primary lesion, the degree of involvement of the gland, whether they be movable or fixed to surrounding tissues, and the degree of the resistance of the patient.

In the cases in which the cervical nodes are not palpably involved, but are to be removed as part of the treatment of the disease, Morestin proceeds as follows: The head is turned slightly away from the field of operation. The incision comprises a star with three branches, the center being at the superior border of the thyroid cartilage, a little

anterior to the sterno-cleido-mastoid muscle. From this center, one incision is carried forward to the symphysis of the chin, the second goes to the anterior border of the mastoid process, and the third travels downward and backward to the clavicle at the posterior border of the sterno-cleido-mastoid. In some cases it is necessary to make a fourth complementary incision extending backward from the inferior end of the third incision along the superior border of the clavicle. The three flaps just outlined are dissected, the upper to above the inferior border of the mandible, the anterior as far as the median line, and the posterior, freed from the aponeurosis of the sternomastoid, well posterior to this muscle. The external jugular vein will be encountered in this dissection with one, two, or three lymph-nodes at its upper extremity. It is ligated above and below and cut at once (Fig. 1). Beginning at the top, the entire inferior border of the mandible is laid bare. The facial artery and veins are cut between clamps in front of the masseter muscle, and the inferior end turned down toward the submaxillary region together with a paramaxillary premasseteric node which generally accompanies them. The submaxillary gland with the nodes found at intervals on its external superior surface is freed from the bone, and the parotid is separated from the anterior border of the sternomastoid as far as the mastoid process. Many veins from the parotid to the external and internal jugulars and to the facial are cut in this dissection. The posterior belly of the digastric is uncovered. Next, going forward, it is necessary to bare the anterior belly of the digastric, to scoop out the interdigastric space, carefully detaching the two or three nodes found there with all the cellular tissue, and to bare the fibres of the mylohyoid to their median raphe. The glands enveloped in cellular tissue are turned back toward the submaxillary region. In the angle formed by the digastric with the inferior border of the jaw, is the submental artery. This is clamped and cut. The submaxillary gland is then easily drawn back, freed from the mylohyoid, and entirely detached by cutting Wharton's duct. After clamping the facial artery as it passes within the digastric and stylohyoid, the emptying of the submaxillary space is completed by laying bare the tendon of the digastric.

In attacking the carotid region, the subhyoid and particularly the anterior belly of the omohyoid are first detached. Then the superficial cervical fascia is incised along the posterior border of the sternomastoid and dissected from behind forward to the anterior border of this muscle, including the external jugular vein with its accompanying lymph-glands. Having freed the anterior surface of the sternomastoid, its inner border is very carefully dissected in its entire length and the carotid region is thus widely opened. The spinal accessory nerve is isolated from the point where it first enters this space until it enters the muscle. Behind this nerve is an important group of glands often buried in a mass of fat. The glands and fat are dissected *en bloc*, the

Fig. 1. Showing the reflection of the skin flaps and exposure of external jugular vein.

Fig. 2. Dissection from above downward of the lymphatic chain along posterior border of internal jugular vein.

dissection being carried to the deep muscles of the neck if necessary. The freed mass is passed under the spinal accessory and is drawn anteriorly. It is then possible to dissect from above downward the entire chain of lymphatics and cellular tissue along the posterior border of the internal jugular vein (Fig. 2). The jugular vein is carefully cleaned from behind forward, and when the thyro-linguo facial trunk is met it is cut at its junction with the jugular; the emptying of the region is completed by liberating the anterior part of all glands and cellular tissue that it contains and the small amount of cellular tissue around the greater cornu of the hyoid (Fig. 3).

The supraclavicular triangle, the cleaning of which is a precautionary measure that it is well to take, can be emptied either before or after the completion of the preceding step without much loss of time. After the anterior border of the sternomastoid has been freed, the posterior border is exposed in its entire length, the superior border of the clavicle is freed, then the posterior belly of the omohyoid, and then the anterior border of the trapezius, and the entire packet of fat and glands in the supraclavicular triangle dissected up from below. Although this tissue is usually easily separated from surrounding organs, close attention must be given to the jugular vein, the brachial plexus, the phrenic nerve, the transverse cervical artery, and one or two large veins from the trapezius to the subclavian.

When the operation is terminated (Fig. 4) all of the gland-bearing tissue of one side of the neck, except the negligible subhyoid, has been raised in one block and not a single gland has been sought, or cut, or pinched with the forceps. In case the sternomastoid muscle is adherent to the fixed and enlarged glandular masses in the anterior or superior carotid regions, the operator can be sure that the internal jugular vein is involved and that both muscle and vein must be sacrificed. As soon as the "star" skin flaps are raised, the skin still being intact, the sternomastoid is cut close to its attachments to the clavicle and mastoid. The jugular vein is bared beneath the omohyoid, divided between clamps, and separated from below upward from the carotid and pneumogastric. The supraclavicular triangle can then be easily cleaned. The common carotid, the internal carotid, and the pneumogastric can usually be spared. As the anterior-superior carotid region is most involved, it is not attacked until the submaxillary, and then the inferior carotid, supraclavicular, and posterior carotid regions are finished. The order of attack may be varied, but should always converge upon the region most involved which is left to the last. Resection of the sternomastoid often shortens the time of operation.

The technique varies a little if the supraclavicular or submaxillary groups are adherent. This last complication is met with frequently and is handled by beginning the operation by cleaning the supraclavicular and carotid regions and ending by the ablation *en bloc* of the submaxillary region with a part of the mandible.

If the glands at the base of the neck are large and adherent, the author advises resection of a half or even the inner two thirds of the clavicle to facilitate the dissection of the region. No bad functional results follow this procedure.

The technique used and the decision as to whether a one- or a several-stage operation should be performed depends upon the location of the tumor and the condition of the patient. The one-stage operation is the operation of choice.

In cancers of the floor of the mouth, Morestin considers it essential to remove all of the lymphatics of both sides of the neck. This operation he performs in three stages: first, total excision of the glands of one side; second, the total excision of the glands of the other side; and third, the excision of the structures of the floor of the mouth with resection of the mandible, usually at the level of the second molar. This procedure is adopted in order to avoid infecting the deep structures of the neck when opening into the mouth cavity. One, or at most, two weeks, are allowed to intervene between the steps.

In cancer of the tongue, the operation is performed preferably in one stage owing to the distortion of tissues which renders a two-stage operation exceedingly difficult. If the tumor is confined to one lateral side of the tongue, the suprahyoid, the anterior and posterior carotid, and the supraclavicular groups of the affected side, and the suprahyoid, the anterior and posterior carotid groups to the anterior belly of the omohyoid of the sound side, are excised. The dissection is commenced from below, always working from below upward and from behind forward. Before opening the buccal cavity, the anterior border of the sternomastoid is sutured to the subhyoid and digastric muscle and to the pharyngeal wall in order to protect the carotid region from infection. The tongue is divided exactly in the midline from tip to base. All remaining tissues are utilized as well as possible to close the defect and the wound packed tightly with iodoform gauze. The only other drainage is one rubber tube placed inferiorly in the line of incision, and another through a stab in the posterior flap. This technique is varied somewhat according to the seat and size of the tumor. Minute details of technique for each case are carefully described.

In cancer of the cheek and of the labial commissure it is necessary to excise all the glands of the affected side with resection of the mandible between the tumor and the submaxillary gland, and all the suprahyoid glands of the opposite side. This operation is performed preferably in two stages, the first being the excision of the tumor with all the suprahyoid glands of both sides; the second, the extensive dissection of all the glands, including the supraclavicular gland, of the affected side.

For ordinary cancers of the lip a one-stage operation is performed. The glandular dissection is not carried beyond the anterior carotid group. The only precaution is to close the incision for the glandular dissection before attacking the tumor.

Fig. 3. Appearance of neck after complete gland resection of one side.

Fig. 4. Showing method of ligating the facial thyrolingual trunk of the internal jugular vein.

In tumors of the pharynx or pharyngo-larynx, the primary tumor is often continuous with the metastatic glandular involvement, and the intervention is exceedingly grave owing to infection. However, if the tonsil is the seat of the primary growth, it can be excised from within the buccal cavity, splitting the cheek if necessary, and the glandular dissection can be carried out at the same, or at a subsequent sitting, with no danger of buccal contamination.

In a chapter devoted to the accidents of operation and sacrifices imposed by the extent of the lesions, the author reaches these conclusions: The sternocleidomastoid muscle may be completely excised without causing any noticeable functional disability to the patient. The internal jugular vein of one side may be readily sacrificed without fear of cerebral stasis. Ligation of both veins is fatal; sometimes part of the wall alone is involved in the growth, and longitudinal section with suturing of the cut edges is possible. Transplantation of the external jugular to take the place of the excised portion of the internal jugular is not difficult, but it is hard to keep the patient alive during the procedure. If symptoms due to venous stasis from ligation or diminution of the internal jugular vein occur, the author recommends compression or ligation of the common carotid. The external carotid may be ligated without fear. Ligation of even one common or internal carotid almost uniformly causes hemiplegia with rapid death. An arterial graft, theoretically indicated, is never successful. Usually the carotid, though completely surrounded by the tumor, is itself free, and an attempt should always be made to separate it from the surrounding tissues. Section of one vagus nerve is never fatal, and hardly ever gives any symptoms. Section of the spinal accessory and hypoglossal nerves leads to loss of function of the muscles supplied by these nerves; otherwise their section is harmless. Wounding of the thoracic duct is not serious, because the ligation of this duct is not followed by any untoward effects. Thus it is seen that the carotid artery alone must be scrupulously guarded. All other structures may be safely divided.

The post-operative complications of this extensive dissection of the neck are few. Bronchopneumonia, as in all surgical treatments of the mouth and pharynx, is frequent. The conditions are peculiarly favorable for extensive infection of the wound — the most common serious complication. As almost all cellular and connective tissue is removed at the time of operation, the inflammation tends to spread along muscles and the walls of blood vessels. As soon as it is seen that the infection is spreading in spite of good drainage, the wound should be widely opened and treated with a powerful antiseptic — tincture of iodine. Ulceration of the internal jugular vein may accompany infection of the wound and is best treated by a tamponade of iodoform gauze which should be gradually and carefully removed several days later. Arterial ulceration, less common,

is almost always fatal. The first sign is an insignificant hæmorrhage, which, stopping spontaneously, is inevitably followed by a larger hæmorrhage unless the bleeding points be effectively cut off. This is almost impossible as the seat of the hæmorrhage is usually at the origin of the external carotid. The author recommends suturing the opening in the bleeding artery and burying it as deeply as possible in the tissues. Œdema of the glottis is usually an immediate complication occurring the day of operation. It is noted only in those cases in which the neighborhood of the glottis and aryteno-epiglottidean folds has been involved. Spasm of the glottis, which may be fatal, is observed at the time of the anæsthesia, the dissection of the second half of the neck, or the ablation of the tumor when this is practiced as a third-stage operation. The operator should always have at hand instruments for a tracheotomy.

The results of the operation depend principally upon whether or not the buccopharyngeal cavity has been entered. If it has not, the mortality is practically nil. Otherwise, a large percentage of cases die of bronchopneumonia. The mortality from this cause and from sepsis, however, can be materially diminished if the carotid space be effectively walled off by sewing the anterior border of the sternomastoid to the subhyoid, the digastric, and the stylopharyngeal muscles. It may be diminished also by performing the operation in several stages. Functional disturbances due to extensive destruction of tissue are remarkably few. The only disturbances are those due to cicatrization, which leaves the tissues thick and hard. Recurrences in early cases are very rare. When the growth does recur it is usually at the original site and is due to a too-limited excision, "rests," the fact that the infiltration was so extensive that it could not be removed completely, or the limiting of the operation by the precarious condition of the patient. The enduring "cured" cases are due first to the broad excision of the primary tumor, but above all to an eradication of the lymphatics, minutely and anatomically conducted.

The author concludes finally that in buccopharyngeal cancers it is absolutely necessary to join excision of the corresponding cervical ganglia to ablation of the tumor if we would entertain the hope of cure; that the extirpation of the ganglia should be systematically performed as a necessary adjunct to any operation looking toward cure and is often more important than the ablation of the tumor itself; that the excision of the cervical ganglia should be made *en bloc*, all the cellular-adipose tissue being removed with the lymphatics, all the important organs of the carotid and supraclavicular regions being bared, and the submaxillary space being completely emptied. It is desirable to complete the operation in one step, particularly in cancer of the tongue or pharynx, and the ideal is to remove all of the tissues, including the tumor, in one mass. Sometimes it is necessary to divide the operation

Fig. 5. The suturing of the anterior border of the sterno-cleido-mastoid to the stylohyoid, subhyoid, and muscles of pharyngeal wall.

Fig. 6. The completed operation with gauze packing and drains in place.

into two or three stages in order to render it supportable. In these cases, ligation, or better, excision of the external carotid with its branches, is a wise precaution. If the buccopharyngeal cavity is opened at the same stage that the carotid region is exposed, the latter should be sealed off from the former by suturing the sternomastoid muscle to the subhyoid, the digastric, and the pharyngeal wall. If the lymphatics are adherent, the sternomastoid, the internal jugular, and pneumogastric of one side may be sacrificed without fear. The internal and common carotid must be preserved at all cost and can almost always be separated from the agglutinated glands which surround them. Resection of the clavicle permits a more extensive operation and the removal of apparently firmly adherent lymphatics. The prognosis is best when the lesions are least advanced, the ganglia most movable, and the subject most resistant. It is the more satisfactory as to distant results the more the eradication is completely, minutely, methodically, and anatomically conducted. All in all, a good technique allows us to face this surgery with confidence, and proves that the radical cure of these cancers can be regularly obtained if the patients are operated upon as here advised and at an opportune time.

ELLIS FISCHEL.

Graham, A.: Tumors of the Carotid Body; with a Report of Two Cases. *Cleveland M. J.*, 1913, xii, 537.
By Surg., Gynec. & Obst.

The author gives a brief resumé of the difficulties that were encountered in classifying the tumors of the carotid body until Stillings classified the carotid gland with the sympathetic nervous system, basing his classification on the large amount of nerve tissue that the gland contains and the close relation that it bears to the sympathetic nervous system.

The only lesion of the carotid body so far described is a characteristic tumor, and the descriptions of all of the new growths have been quite similar. Up to 1913, thirty-five cases have been reported.

The author gives two additional case histories with descriptions of the operations. The operations were performed by Crile. A very complete description of both the gross and the microscopical structure of these tumors forms the larger part of the article. There are nine illustrations of the specimens and microscopical sections. The tumors described correspond very closely clinically, anatomically, and histologically to the other tumors of the carotid gland reported. Graham does not attempt to classify the tumors specifically, as the embryological origin of the gland has not been definitely settled.

In thirty-six cases of which complete case reports are given, the tumors occurred in 19 males and 17 females. The average age at which they were found was 36 years; the youngest patient was 7 years of age, and the oldest, 63. In twenty-two cases all three carotids were ligated, and in five, the external carotid alone. In seven cases the tumor was re-

moved without injury to the vessels. In six cases there was injury to the vagus nerve; in eight, to the hypoglossal; and in four, to the sympathetic. Hemiplegia occurred four times. Four of these patients lived and one died. In one case the patient suffered cerebral hemorrhage but recovered. In four cases there were recurrences: in three, after ligation of the carotid with removal of the tumor, and in one, after the removal of the tumor only. Two cases recurred within a year, one in four months, and the other in two months. The results in two cases operated upon are not stated. In two cases death resulted from pneumonia; in three, from hemorrhage and shock; and in one, from hemiplegia. In one case death occurred from cerebral hemorrhage nine months after the patient left the hospital, and in another, from recurrence at the end of a year. A complete bibliography is appended.

DONALD GORDON.

Guibal, P.: A Contribution to the Surgery of the Neck. Is Unilateral Resection of the Internal Jugular and Pneumogastric Harmless? (Contribution à la chirurgie du cou. La résection unilatérale de la jugulaire interne et du pneumogastric, est-elle inoffensive?) *Rev. de chir.*, 1913, xlviii, 96.
By Journal de Chirurgie.

Unilateral resection of the internal jugular and pneumogastric is generally considered harmless. The following cases added to several others already published tend to disprove this.

A man of fifty-five was suffering from a pavement cell epithelioma of the right vocal cord and there were scarcely perceptible lymph nodes along the course of the left carotid.

At the first operation the ganglions, the left internal jugular, and the pneumogastric were resected with no immediate trouble. Later a tracheotomy was performed. At five in the evening the patient was semi-comatose, respiration 40, pulse 118, temperature 38° C. On auscultation there was a splenopneumonia of the left side and a paresis of the right. The next day complete coma and right hemiplegia, respiration 40, pulse 130, temperature 38° C., and a double pneumonia. Death occurred forty-eight hours after operation.

Guibal believed that the rapid oncoming of pulmonary lesions could be ascribed only to the section of the pneumogastric, although such trouble after surgical section of the vagus is rare. The cerebral symptoms could be ascribed only to the ligation of the jugular vein. There were no symptoms or signs of trouble in the carotids. Autopsy was not possible.

In this case the symptoms were similar to those reported by Luise, Kummer, and von Bruns, which were controlled by autopsy. The cerebral symptoms were due to venous hypertension of the brain, giving symptoms on both sides, but especially on the side of the ligation. In general, these symptoms are due to insufficiency of the remaining jugular. Exploration of the jugular before operation would be of no

avail, however, as aphasia of the sinus portion would not be noted.

J. OKINCZYC.

Edmunds, W.: Thyroid. *J. Pathol. & Bacteriol.*, 1913, xviii, No. 1.
By Surg., Gynec. & Obst.

This paper is the ninth of a series by the author and deals largely with the metabolism of sugars in dogs who have undergone total thyro-parathyroidectomy and have survived on a milk diet supplemented at times by additional calcium lactate. The author reports the cases of dogs living and in good condition eight and fifteen months after total thyro-parathyroidectomy, having been kept on a milk diet during that time. He adds the interesting observation that animals will survive total thyro-parathyroidectomy if they are fed large quantities of milk but that they will not survive if the milk is obtained from thyroidectomized animals. This would indicate that the comparatively larger amount of calcium salts ingested in the milk does not alone account for the survival. Comparing the results of urinalysis after feeding glucose and lactose to both normal and thyro-parathyroidectomized dogs, the author concludes from a small number of observations that in dogs the thyroid gland hinders the assimilation of sugar, while the parathyroid gland favors the assimilation, and that the parathyroid action favoring assimilation is greater than the thyroid action hindering it.

H. B. LODER.

Busch: Pathological Changes of the Thyroid Gland in Syphilis (Zur Frage der Schilddrüsenveränderungen bei Syphilis). Dissertation, St. Peterb., 1913.
By Zentralbl. f. d. ges. Chir. u. i. Grenzgeb.

The author investigated the morphological changes of the thyroid gland in congenital and acquired syphilis. To differentiate syphilitic changes, the influence of other factors, especially of infectious diseases, must be excluded. In the first chapter the "iron-hard strumitis" first described by Riedel is mentioned and is considered probably not a clinical entity but as due to syphilis or tuberculosis.

In the second chapter Busch gives a short review of the investigations of thirty-six cases of syphilitic thyroids reported in the literature. Of these, fifteen were carefully examined. He concludes that there are two syphilitic processes that can occur in the thyroid gland: the interstitial and the gummatous. In the remaining twenty-one cases the diagnosis was made *ex juvantibus*. Of special interest are seven cases of definite Basedow's disease to which the author adds two more. In all of these potassium iodide was administered in large doses. It was well tolerated and caused permanent improvement notwithstanding symptoms of hyperthyroidism and Kocher's warning not to employ iodine in goiter cases.

The author's conclusions tabulated in chapter four are as follows: The average weight of the thyroid gland of premature syphilitic fetuses was 32 per cent greater than those of the control cases; in full-term syphilitic children, however, the weight

was 36.6 per cent less. In premature syphilitic children the inter- and intralobular connective tissue was a little stronger. In adults with acquired syphilis the interlobular connective tissue was more developed. The average size of the gland lobules and follicles was larger in all syphilitic cases than that of the controls. In the premature cases the dark, firm colloid made its appearance earlier and was more frequent. Vacuolization was marked whereas in the controls it was entirely absent. In full-term syphilitic children and in adults the dark colloid also occurred. Vacuolization, however, was less marked than in the control cases. Cellular desquamation appeared more marked only in the premature syphilitic children. No appreciable difference was found in the size and form of the nuclei of the follicular epithelium. The number of fat droplets in the follicle cells was greater in syphilitic than in normal thyroids. The quantity of blood in the syphilitic gland was greater. The condition of the vessels was surprising. The changes which in other organs are considered as pathognomonic for syphilis occurred in the thyroid only exceptionally and then only to a slight degree. In all of the cases there were noted conglomerations of nuclei which must be considered as the antecedent stage of a follicle. They are, therefore, more common in young than in old glands.

From all of these findings the conclusion must be drawn that changes of the thyroid gland in congenital, as well as in acquired, syphilis are not in any way specific. They are more quantitative than qualitative in nature. In congenital syphilis the gland develops earlier, colloid appears earlier in its follicles, and fat appears in the follicle epithelium earlier and in larger quantity than in the controls. The functional changes of syphilitic glands naturally must be quantitative in nature. In view of the microscopical findings, the function must begin very early. Later it must be inferior to that of normal glands. Extensive chemical and hematological investigations must decide this. Six microphotographs and twelve large tables accompany the monograph.

STROMBERG.

Krecke, A.: The Effect of Thyroidectomy on Thyroid Affections (Der Einfluss der Strumektomie auf die Thyreosen). *Deutsche Ztschr. f. Nervenhe.*, 1913, xlvii-xlviii, Festschr. v. Strümpell, 337.
By Zentralbl. f. d. ges. Chir. u. i. Grenzgeb.

Krecke asserts that from 50 to 60 per cent of his goiter patients have general disorders either of the nervous system, the circulatory system, or of metabolism. These disturbances he designates as "thyreoses" and divides into three grades. Of the first grade are general disorders of metabolism accompanied by merely a subjective feeling of palpitation. The second grade includes those cases with tachycardia and a pulse beat up to 120 per minute, but without exophthalmos. The third grade includes cases that show the typical picture of Basedow's disease.

The author calls attention to the occult thyroid disorders which are difficult to diagnose. For confirmation of the diagnosis he recommends the administration of iodine or thyroid gland tablets which increase the thyroid symptoms. Kocher's blood picture and the ineffectiveness of digitalis on the pulse also help to confirm the diagnosis.

Of 87 patients operated upon for goiter, 54 had thyroid symptoms. In 32 of these cases the symptoms were of the first degree, in 17, of the second degree, and in 5, of the third degree. Later reports from 44 of these patients showed that 50 per cent recovered and 30 per cent had improved. A small number were not helped at all, or helped only slightly. It is probable that these had nervous disturbances of some other origin, or that other ductless glands were involved.

ERNST SCHULTZE.

Wilson, L. B.: Notes on the Pathology of Simple and Exophthalmic Goiter. *Med. Rec.*, 1913, lxxxiv, 373. By Surg., Gynec. & Obst.

This paper is a review of the pathology of the thyroid glands removed from 1,208 patients in the Mayo clinic who presented symptoms that would ordinarily be diagnosed as exophthalmic goiter. For purposes of control, the pathology of 585 thyroids removed from patients whose condition would ordinarily be diagnosed as simple goiter are also given.

The following classification of the histological conditions has been followed in these studies:

- I. Embryonic (undeveloped) thyroid.
- II. Normal (resting) thyroid.
- III. Vascular changes.
 1. Hyperæmia.
 2. Hæmorrhage (including resulting cyst formation).
- IV. Inflammations.
- V. Progressive changes.
 1. Hypertrophy (functional, with hyperæmia).
 2. Hyperplasia ("exophthalmic" goiter).
 3. Adenomatosis (multiplication of acini without encapsulation).
 4. Regeneration (of previously atrophic parenchyma).
- VI. Retrogressive changes.
 1. Retention of secretion (colloid goiter).
 2. Atrophy (of parenchyma).
 3. Degenerations.
 - a. Colloid (of parenchyma and stroma).
 - b. Hyaline.
 - c. Amyloid.
 - d. Calcareous.
 - e. Cystic.
- VII. Tumors.
 1. Benign.
 - a. Foetal adenomata (encapsulated).
 - b. Adult adenomata (encapsulated).
 2. Malignant.
 - a. Mesotheliomata.
 - b. Carcinomata.
 - c. Sarcomata.

Much of the trouble in interpreting the pathology of the thyroid gland has come from the associated difficulty of definitely grouping the clinical symptoms. Recently, however, Plummer has sharply differentiated the toxic symptoms of goiter into two clinical groups: (1) toxic exophthalmic; and (2) toxic non-exophthalmic. Plummer points out that beside sooner or later exhibiting the symptom of exophthalmos, the cases of the first group are acute and in many respects resemble the symptoms of acute alcoholism, while those of the second group are chronic and in many respects parallel the symptoms associated with arteriosclerosis from chronic alcoholism. In this latter group are many cases so mildly or so aberrantly toxic that clinicians in the past have frequently listed them as simple goiters. Plummer suggests that this latter term should be abandoned by the clinician and the term "non-toxic" substituted for it.

The author's conclusions were as follows:

1. A detailed pathological study of fixed tissue preparations of the thyroids removed from adults and the finding thereby of marked primary parenchymatous hypertrophy and hyperplasia permits the pathologist to diagnose exophthalmic goiter with above ninety-five per cent accuracy. At the same time, a consideration of the data above mentioned will permit him to estimate the stage of the disease in about eighty per cent of the cases, and the severity of the disease in about seventy-five per cent of the cases.

2. A similar study of thyroids from adult patients and the finding thereby of no marked hypertrophy, hyperplasia, or regeneration of parenchyma will permit the pathologist to diagnose non-toxic goiter with about seventy-five per cent accuracy.

3. The most difficult cases to diagnose pathologically are those of the clinical toxic non-exophthalmic type. While these are not hyperplastic, they may fall into any of the other above-mentioned groups. Our knowledge of these cases is still too incomplete to permit us to draw conclusions concerning the details of their pathology.

4. On the whole, it would appear that the pathologist has quite as much data for the estimation of the clinical symptoms of exophthalmic goiter from the pathological data that can be obtained from a study of the thyroid as he has to estimate the clinical symptoms of Bright's disease from the pathological data that can be obtained from the study of the kidney.

Roussy, G., and Clunet, J.: Lesions of the Thyroid in Basedow's Disease (*Lésions du corps thyroïde dans la maladie de Basedow*). *Rev. Neurol.*, 1913, xxi, 1. By Journal de Chirurgie.

It is generally agreed that Basedow's disease is due to a disturbance of the thyroid, and treatment is directed to the thyroid. There has been great difference of opinion, however, as to just what condition of the thyroid it is that causes the disease.

Roussy and Clunet report an histological study of ten thyroids from patients who presented a Basedow syndrome. Three of these patients had true Basedow's disease; three, goiter with secondary Basedowian changes; and two, thyroid cancer presenting the Basedow syndrome.

In the five cases of true Basedow's disease in young subjects in whom exophthalmos, tachycardia, and trembling appeared at the same time as diffuse hypertrophy of the thyroid, the structure of the gland was found to be homogeneous throughout and to present the following characteristics: (1) Hypertrophy and proliferation of cells which showed a tendency to become cylindrical and to form intra-acinous vegetations; (2) the lumens of the acini were very small, filled with chromophobic colloid, and slightly or not at all retractile; (3) atrophy of the stroma; and (4) in three cases out of five there were true lymphoid follicles in the stroma, some of which presented a clear center.

In the three cases of goiter, there were found different types of the structure of simple goiters in different areas (cysto-adenoma, simple colloid goiter, foetal goiter and goiter with small acini; beginning, advanced, and calcified sclerosis, and myxoid and colloid degeneration of the stroma). On examining a

large number of sections, however, the authors found in all three cases small areas which presented the histological picture of true Basedow's disease.

In the two cases of cancer with the Basedow syndrome the cancer cell was a cylindrical thyroid cell, secreting a ductile chromophobic colloid.

The authors therefore regard the thyroid picture in Basedow's disease as characterized by proliferation of cells, cylindro-cubical in form, and a ductile and chromophobic state of the colloid. The presence of true lymphoid follicles in the stroma is frequent but not specific.

In true Basedow's disease these lesions extend throughout the gland: in the goiter with secondary Basedowian changes, they exist in islands; and in thyroid cancer presenting Basedow's syndrome they characterize the neoplastic changes.

The Basedowian structure may be observed not only in this disease, but in cases of intense thyroid hyperplasia, or rapid development, such as occurs in animals where compensatory hypertrophy has followed removal of nine-tenths of the thyroid tissue.

These conclusions agree with those of Rubens Deval (4 cases) in France; of Wilson (294 cases) in the United States; of Zander (14 cases) in Germany; and of Kocher in Switzerland. JEAN CLUNET.

SURGERY OF THE CHEST

CHEST WALL AND BREAST

Pfahler, G. E.: The Treatment of Recurrence and Metastases from Carcinoma of the Breast. *Tr. Internat. Cong. Med.*, Lond., 1913, Aug. By Surg., Gynec. & Obst.

This report is based upon a study of fifteen cases which have yielded good results from treatment with X-rays. The patients have remained well from one to nine years.

In addition to the use of the X-rays, thyroid extract was prescribed in small doses, beginning with one half grain, and being gradually increased to one and a half grains, three times a day. The addition of thyroid extract was based upon two theories: first, that as a result of the X-ray treatment, the thyroid secretions are progressively diminished; and second, that at the age when carcinoma develops, the thyroid secretion naturally tends to diminish.

The treatment described has seemed to increase the nutritive powers of the body, and to give better results than were obtained without thyroid extract.

The object of the article is to prove that even advanced carcinoma can be influenced by X-ray therapy, and that there should be no hesitation in ordering X-ray treatment immediately after any operation for the removal of carcinoma of the breast, or at the latest, when recurrence is noted.

The X-ray treatment must be thorough; the

disease must be attacked from as many different directions as possible, and the skin must be protected by filtration. Following these directions we may hope for better results in the future.

Guleke: Penetrating Injuries of the Chest and Abdomen (Über penetrierende Brustbauchverletzungen). *Arch. f. klin. Chir.*, 1913, ci, 1030. By Zentralbl. f. d. ges. Chir. u. i. Grenzgeb.

In penetrating wounds of the thorax there are great diagnostic difficulties in determining whether an intra-abdominal injury also is present. The usual symptoms in such an injury are ambiguous. Muscular rigidity, for example, is found in the beginning of most injuries affecting the lower thoracic region and the diaphragm. In a wound of the diaphragm that did not penetrate the peritoneum Guleke noted a diffuse muscular defense. The retrogression or increase in these phenomena is more valuable in cases which can be observed for a longer period of time. The pulse fails as a diagnostic sign in thoraco-abdominal injuries, because injuries to the pleura often produce a vagus pulse (Sauerbruch, Walther). There is no certain pathognomonic sign of a simultaneous abdominal injury in penetrating wounds of the thorax. The diagnosis may be only very probable from the character and nature of the injury. Observation of from three to four hours is of some assistance.

In regard to the question as to whether a trans-

pleural operation or a laparotomy should be performed in such cases, Guleke believes on the basis of his experience that in large wounds the operation should be transpleural. After the opening in the diaphragm is enlarged, the injured abdominal viscera can be taken care of and the diaphragm sutured. If injury to deeper or retroperitoneal organs is suspected, a laparotomy also should be performed. In narrow and small wound channels produced by a bullet or a fine instrument only a laparotomy should be considered. Suturing the diaphragm is not necessary in such cases.

Five case reports given were as follows: (1) Incised wound of thorax and abdomen with prolapse of the intestine; laparotomy; cure. (2) Thoraco-abdominal puncture, injury to omentum; transpleural operation plus laparotomy, suture of diaphragm, later rib resection and pneumofixation because of pneumothorax; peritonitis; exitus. (3) Percutaneous diaphragmatic puncture; thoracotomy; healing; the puncture ran tangentially to the diaphragm at the rib insertion without injury to the peritoneum. (4) Puncture of chest and abdomen, stomach punctured; laparotomy; peritonitis; exitus. (5) Gunshot wound of thorax and abdomen wound of spleen; laparotomy; healing.

SCHUMACHER.

Kaefer, N.: The Treatment of Fractures of the Clavicle (Zur Behandlung des Schlüsselbeinbruchs). *München. med. Wchnschr.*, 1913, lx, 1599.
By Zentralbl. f. d. ges. Chir. u. i. Grenzgeb.

For fractures of the clavicle Kaefer recommends a bandage which is applied as follows: The affected shoulder is firmly pulled backward by one assistant, and the elbow lifted upward by another. A cotton pad is then inserted in the axilla. The arm is pressed against the thorax, and held in this position firmly. The fragment pieces must be well adapted to each other. The point of dislocation is covered with mastisol. Upon this a gauze pad is laid. A strip of gauze is then stretched over the pad. A shoulder piece of plaster of Paris, 20 cm. long, is then modelled around the shoulder and a Desault bandage placed over the moist plaster cast. The twists of the bandage are kept from unwinding by mastisol spread upon the skin. The plaster of Paris cast allows the Desault bandage to be applied very firmly and thus the whole dressing is given great stability. The sound shoulder remains free. In the third week the bandage is taken off and massage and exercise are begun.

HESSE.

Dräseke: Scaphoid Scapula (Zur Kenntnis der Scapula scaphoidea). *Ztschr. f. d. Erforsch. u. Behandl. d. jugendl. Schwachsinn.*, 1913, vi, 468.

By Zentralbl. f. d. ges. Chir. u. i. Grenzgeb.

The deformity of the shoulder-blade described frequently under the name of scaphoid scapula has been found by Dräseke in 10 to 20 per cent of the cases of Hamburg school children and in 30 per cent of cases of children in the reform school. Kellner found it even more frequently in idiots, so that it is

doubtless a sign of degeneracy. Congenital syphilis is not the sole factor (Graves). Other etiological factors are alcoholism, tuberculosis, severe nervous disease of ancestors, and rickets.

DUNCKER.

Boissonnas: A Contribution to the Symptomatology and Therapy of Thymus Hypertrophy (Ein Beitrag zur Symptomatologie und Therapie der Thymus-Hypertrophie). *Ztschr. f. Kinderheilk.*, 1913, vii, 472.

By Zentralbl. f. d. ges. Chir. u. i. Grenzgeb.

CASE 1. A two-months-old girl of healthy parentage. For three weeks noisy respiration, vomiting, cyanosis, inspiratory stridor; a rounded tumor in the jugulum; voice free; dullness under the manubrium with corresponding X-ray shadow. Diagnosis: Thymus hypertrophy with compression of the trachea. Operation: Complete thymectomy. Weight of thymus gland 20 g. Course: Injury of softened trachea by glass drain followed by severe bronchitis and tracheotomy. Eighteen days after the operation, death from bronchopneumonia.

CASE 2. A boy, one and a quarter months old, of sound parentage. Since birth, daily attacks of suffocation. Cyanosis; inspiratory and expiratory stridor; dullness over the thymus. Diagnosis: Thymus hypertrophy. Operation: Resection of the thymus gland. Patient well after three to four months, with slight signs of rickets.

CASE 3. A girl, four and one half years old, of healthy family. Since second week of life audible respirations, attacks of dyspnoea and difficulty in taking nutrition. Cyanosis, inspiratory and expiratory stridor. X-ray treatment. In nine weeks seven X-ray exposures with 2 H.

Of the physical methods, radioscopy and radiography are the most certain for demonstrating thymus hyperplasia. Stridor vestibularis, congenital stenosis of the trachea, mediastinal abscesses, and enlarged bronchial glands must be excluded. In case of severe symptoms with asphyxia an immediate partial thymectomy should be performed, possibly with resection of the sternum. In some cases healing is very gradual because the tracheal rings are soft. Tracheotomy should always be avoided. Intubation gives only temporary relief. In the intermittent forms of thymus hyperplasia, X-ray treatments can be used, but only under clinical observation. At first the condition may become worse. In thymus hyperplasia on a syphilitic basis, specific treatment should be combined with brine baths, which give favorable results.

KLOSE.

TRACHEA AND LUNGS

Mouret, J.: A New Position for Bronchoscopy and Œsophagoscopy and Its Advantages over the Classic Position (Une nouvelle position pour bronchoscopie et œsophagoscopie et son avantage sur la position classique). *Tr. Internat. Cong. Med.*, Lond., 1913, Augus. By Surg., Gynec. & Obst.

As a position for bronchoscopy and œsophagoscopy Mouret prefers to have the trunk and pelvis

bent far forward, and the head extended. If the bronchoscopy or œsophagoscopy is to be done under local anæsthesia, the patient is seated astride a chair; if under general anæsthesia, he lies in a crouching position on his side.

While in the classic position (Killian, Brünings) the bucco-pharyngeal angle is opened from above, the head being lifted and placed in forced flexion, by Mouret's method it is entered from below and the bucco-œsophageal angle is opened "at the side toward the vertebral column." The pelvis is carried far backward and the shoulders far forward.

The position with the trunk and pelvis inclined forward offers several advantages: (1) The patient is in a much less painful position. (2) The operator is always in front of the patient. (3) The introduction of the tube is easier, because the operator is in a more favorable position for introducing it and because the vertebral column, being stretched, rather than packed down as in the ordinary position, does not offer any obstacle to its passage.

The author has performed numerous bronchoscopies and œsophagoscopies by this method for tumors and foreign bodies. For several months he treated an epithelioma of the lower third of the trachea that had been causing terrible crises of asphyxia. He has removed foreign bodies from the bronchi of children of eight or nine years of age under cocaine anæsthesia. Five photographs and thirteen diagrammatic figures representing the different steps in the operation are given.

Lorenz, H. E.: Bronchiogenic Carcinoma (Das bronchiogene Carcinom). *Beitr. z. klin. Chir.*, 1913, lxxxv, 599.

By Zentralbl. f. d. ges. Chir. u. i. Grenzgeb.

After an embryological survey, the various theories as to the mode of development of lateral cervical fistulæ and cysts are discussed. The author concludes that the second bronchial cleft is responsible for the formation of a series of lateral fistulæ and that therefore these should continue to be called the bronchiogenic fistulæ. Not all lateral fistulæ, however, are derived from the second cleft. A number, according to the author's view, originate from the thymo-pharyngeal duct. However, as this latter is also a bronchiogenic formation, it is not necessary to give these varieties of fistulæ a separate name. Bronchiogenic carcinomas give a typical clinical picture: as a rule a small nodule first appears in the neck below the jaw. In this condition an incorrect diagnosis is the rule and the possibility of a bronchiogenic carcinoma is only rarely thought of.

Usually an incision is made. This does not heal, and the patient rapidly advances to incurability. The tumor begins to grow rapidly and infiltrates the underlying tissues; neuralgic pains radiating in all directions are felt; the regional lymph glands become involved and hard nodes may form on the opposite side of the neck. At the operation even in early stages there are found quite regularly adhesions with the sterno-cleido-mastoid muscle and also with the

exterior carotid and its branches which naturally must be resected. Ligation of the interior carotid often cannot be avoided. At times resection of the vagus is expedient. Microscopically the tumor looks like a carcinoma of the skin or pharyngeal mucous membrane.

The diagnosis must be made by exclusion on the basis of the absence of primary carcinomas in other places. The differential diagnosis from carcinoma of the parotid or submaxillary gland is very difficult. It is especially difficult in the latter case because here an inflammatory tumor occasionally simulates a neoplasm. The diagnosis from carcinoma or struma of an aberrant thyroid may also be very difficult. The treatment of this extremely malignant neoplasm consists only of radical extirpation of the tumor. Even with extensive operative procedures the prognosis is unfavorable. Statistics comprising sixty-four cases are appended.

COLLEY.

Citelli, S.: Pituitrin in Operative and Spontaneous Hæmorrhage of the Respiratory Passages (La pituitrine dans les hémorragies opératoires et spontanées des voies respiratoires). *Tr. Internat. Cong. Med.*, Lond., 1913, Aug.

By Surg., Gynec. & Obst.

The aqueous extract of the pituitary gland has recently been shown to be very useful in prolonged labor caused by atony of the uterus and in hæmorrhage of the uterus because it causes progressive and prolonged contraction of the uterine muscle fibers. From these facts Citelli concluded that perhaps it would give good results in spontaneous and operative hæmorrhage of the respiratory passages, especially in resection of the inferior turbinates. He experimented with an aqueous extract of the posterior lobe of the hypophysis in various conditions.

The author used the extract for spontaneous hæmorrhage in epistaxis, hæmorrhage from the mouth and nose in hæmorrhagic diathesis, and in bronchorrhagia. In operative cases he used it for resection of the turbinates, submucous resection of the septum in nasal polyps, operations on the nasal sinuses, tonsillectomies, etc. In almost all of these the results were excellent. He injected a cubic centimeter of pituitrin beneath the skin or into the muscles about a quarter of an hour before the operation. During and after the operation the hæmorrhage was very slight and he was spared much sponging and tamponing of the nose. If necessary, one or two injections may be made after the operation.

HEART AND VASCULAR SYSTEM

Leporsky: A Case of Prolonged Cessation of Heart Action Resulting from a Needle Injury to the Heart (Ein Fall von langdauernden Herzstillstand infolge einer Nadelverletzung des Herzens). *Russk. Vrach.*, 1913, xii, 118.

By Zentralbl. f. d. ges. Chir. u. i. Grenzgeb.

The author describes the case of a man 26 years of age who fell down six steps on his breast and ran a

needle into the left half of the thorax. The patient was brought to the clinic at once. At that time he was pale and every movement of the hands caused pain. The needle could be felt in the second intercostal space. It moved up and down synchronously with the pulse. Auscultation and percussion revealed nothing abnormal. The pulse was regular but somewhat rapid.

The needle was removed under local anæsthesia. The instant it was removed the patient ceased breathing and immediately afterward the pulse stopped. All possible restorative measures were undertaken, and at the end of twenty minutes the pulse could be felt again. In five minutes it stopped a second time but reappeared again in a little while. This was repeated twice.

The author believes that the phenomena noted were caused, not by a needle prick of the heart itself, but by a needle scratch of the epicardium when the needle was withdrawn that stimulated the inhibitory apparatus of the heart. The same result he has produced experimentally. JOFFE.

Dean, G., and Falconer, A. W.: Primary Tumors of Valves of the Heart. *J. Pathol. & Bacteriol.*, 1913, xviii, No. 1. By Surg., Gynec. & Obst.

The authors report a case of tumor of the pulmonary valve, discovered at autopsy in a male, fifty-three years of age, who died of rupture of a sacculated aneurysm of the aorta. During life, there had been no clinical signs to suggest pulmonary valve disturbance. The tumor, pedunculated, the size of a raspberry, arose from the ventricular cusp of the pulmonary valve, which was otherwise entirely normal. Microscopically, the tumor consisted in part of myxomatous tissue and in part of hyaline connective tissue. It was covered by endothelium and was without vessels. The authors collected from the literature thirteen cases of heart valve tumor of similar structure, three pulmonary, three aortic, five tricuspid, and two mitral. They discuss at some length the pathology of the growths and the varying views that have been expressed as to their nature. H. B. LODER.

Delagenière, H.: Pericardiolysis in a Certain Disease of the Heart, or Supercardiac Thoracotomy (De la péricardiolyse dans une certaine affection cardiaque, ou de la thoracotomie supéricardique). *Arch. prov. de Chir.*, 1913, xxii, 317. By Journal de Chirurgie.

Delagenière describes an operation that he calls "pericardiolysis," and which consists in freeing the anterior surface of the pericardium by resecting the part of the thoracic wall that covers the pericardium. This enables the heart to contract with its normal

rhythm and sweep, even if there are adhesions between the heart and the pericardium. Heretofore, only limited resections had been performed, involving portions of the third, fourth, fifth, and even the sixth ribs where they came into relation with the pericardium. Only once had a transverse section of the sternum been removed (Thornburn).

Among thirty-eight cases published there had been only one death from operation, thirty-one successful cases, and six failures. In all of the unsuccessful cases there were valvular lesions. The lack of success may have been due to the fact that the operation was not extensive enough and did not alter the cardiac action sufficiently.

Delagenière describes his own case, that of a woman twenty-eight years of age with a severe cardiac lesion involving the right side of the heart as shown by cyanosis of the lower limbs and a true venous pulse.

Under chloroform anæsthesia a skin incision was made outlining a flap which covered the whole precardiac region. A hole was bored in the lower end of the sternum and the skin incision followed. The sternum, the cartilages, and left ribs, the sternum again above, and the false ribs on the right were resected in succession. The flap was raised and detached from the pericardium and pleura. As soon as the flap was removed the heart bounded into the field of operation, and, striking on the upper intracavicular notch of the sternum, caused asphyxiation. Three more centimeters were removed. The heart then seemed to beat with less difficulty and respiration was normal. The patient was able to get up on the fifteenth day. Before the operation she could do nothing. She now does her daily work as a charwoman and has no cyanosis or œdema. On inspection the rise and fall of the heart on pulsation can be easily seen. The pulse is 78 and regular. Arterial tension is normal.

The author believes that all cases of adherent mediastino-pericarditis should be treated surgically. Often they follow purulent pleurisy and sometimes tubercular pleurisy. In these cases simple resection of from six to nine centimeters of the fourth, fifth, and sixth ribs may suffice. In adherent pericarditis following acute pericarditis with or without valvular lesions, however, only the extensive operation described by Delagenière frees the heart and great vessels completely. This operation is indicated also in ill-defined cardiac disease with or without valvular lesions when there are signs of stasis, as in involvement of the right heart.

The case described belongs in this category and two years after the operation the patient expresses herself as delighted with the result.

GEORGE LABEY.

SURGERY OF THE ABDOMEN

ABDOMINAL WALL AND PERITONEUM

Petroff, N. N.: Experimental Contributions on the Subject of Abdominal Drainage (Experimentelle Beiträge zur Frage der Bauchhöhlendrainage). *Chir. arch. Veliaminova*, 1913, xxix, 195
By Zentralbl. f. d. ges. Chir. u. i. Grenzgeb.

The author has dealt with the question as to whether a drainage tube or tampon introduced into the abdominal cavity is capable of guaranteeing good drainage, or whether the drain is at once encapsulated and separated from the free abdominal cavity by adhesions. His method of determining this was as follows: A tampon or drainage tube was placed in the artificially infected peritoneal cavity of rabbits. After one to two days, Berlin blue was injected into the abdominal cavity at a point as far as possible from the site of drainage. The tube or tampon were carefully watched. If the coloring matter did not appear in the course of an hour, the animal was killed and an autopsy was performed. The following results were obtained from thirty-six animal experiments: Tampons placed in the aseptic abdominal cavity showed diminished capillarity from the free peritoneal cavity after from five to six hours, and none after from fifteen to twenty-four hours. This depends on the formation of adhesions and the loss of the hygroscopic properties of the gauze. Tampons introduced into the infected peritoneal cavity were adhered to the intestinal loops but were less isolated than in the aseptic cavity. The loss of the hygroscopic properties of the gauze is just as apparent as in the aseptic abdominal cavity. With great regularity it was noticed that the coloring fluid flowed out of the wound next to the tampon, and that the gauze itself did not drain off the fluid. Hence only that part of the tampon which was adjacent to the margin of the wound was of value for drainage. The deeper parts of the tampon were surrounded by adhesions and lay amid the abdominal organs as mucous foreign bodies. The conclusion for practical surgery is that tamponade is well suited to stop hæmorrhage and to isolate a certain region of the peritoneum, but is not suitable for purposes of drainage. For the latter it is sufficient to introduce very short tampons into the peritoneal cavity. Rubber drainage tubes formed fewer adhesions, but the fenestra were frequently occluded by the intestines. In the presence of an exudate the dye drained off even after fifteen hours. In the case of glass drains no isolating adhesions were noticed up to the forty-eighth hour. Petroff discovered that surrounding the drainage tube with gauze, as practiced by many surgeons, paralyzes the suction power of the drain. On the other hand, the introduction of gauze into the lumen of the tube, if the gauze is frequently changed, is designated as rational, because it increases the suction. On the basis of these experiments the author concludes that

drainage of the free peritoneal cavity is possible, at least in the first forty-eight hours. The best drainage material is glass drains.
HESSE.

Allen, L. W.: Ileo-Appendicular Hernia of the Appendix. *Surg., Gynec. & Obst.*, 1913, xvii, 191.
By Surg., Gynec. & Obst.

The author reviews the history and development of the pericæcal folds and fossæ in general and the anatomy and pathology of the ileo-appendicular fossa in particular, with special reference to hernias of the appendix into the latter. To the two cases found in the literature he adds a third.

Moynihan's classification of the pericæcal folds and fossæ clears up the confusion of the past. The primary folds are: (1) the ileocolic or anterior vascular folds; (2) the accessory ileocolic fold; (3) the ileo-appendicular fold; and (4) the meso-appendix or posterior vascular fold. The fossæ formed by these are: (1) the ileocolic fossa; (2) the accessory ileocolic fossa; and (3) the ileo-appendicular fossa. Secondary fossæ are dependent upon secondary physiological adhesions.

In describing the ileo-appendicular fold, Allen states that it contains muscle fibers. To these Luschke ascribes its origin. Moynihan, on the other hand, considers the ileo-appendicular fold to be both muscular and vascular, and bases his views upon the embryological development.

The ileo-appendicular fossa is subject to two pathological conditions, cysts and hernias. The hernias are dependent upon the size of the opening, the firmness of the edge, and the condition of the intestines, plus abdominal pressure.

Von Wistinghausen: Retrograde Incarceration of the Intestine in Hernias (Über retrograde Darmeinklemmung bei Brüchen). *Deutsche Ztschr. f. Chir.*, 1913, cxvii, 212.

By Zentralbl. f. d. ges. Chir. u. i. Grenzgeb.

In 1895 Maydl declared that a retrograde incarceration was possible only in organs that end blindly, such, for example, as the appendix, and that there is no possibility of retrograde dislocation of the intestinal coil, as the vessels of the mesentery pursue a course perpendicular to the long axis of the bowel and do not pass the hernial sac. This has been shown to be erroneous. In retrograde incarceration, as is well known, the outgoing and incoming loops of bowel are caught in the hernial sac, while the portion of intestine that connects the two loops, the so-called middle piece, lies free in the abdominal cavity. There are three possibilities for the development of retrograde incarceration: The retromigration of the middle piece, as it is forced back in the reposition, or the entrance of two or more intestinal loops into the hernial sac either simultaneously or successively, whereby the middle piece remains in the abdomen. There are cases in

which the coils lying in the hernial sac are healthy and without constrictions, while the middle piece is gangrenous. In other cases the hernial loops may be slightly or severely injured, with moderate to severe damage to the middle loop. Finally, there may be gangrene of all of the loops or marked alterations in the hernial loops, with slight or no injury of the mid-piece. The mesentery of the mid-piece may not be incarcerated, while the latter is completely gangrenous, or the mesentery may show visible alteration, even though it lies quietly in the abdominal cavity. Experiments on the cadaver have shown that in such incarcerations the mid-piece, if distended with gas, becomes sharply kinked, whereby a constricting ring forms in the mesentery (Zugarkade). In this sharp angle the vessels become kinked and nutritional disturbances to the intestine result. The author, however, was not able to make the same findings. Experiments on the intestine of dogs showed that gangrene occurred only when the mesentery of the middle part was drawn into the hernial opening. In spite of the objection that it cannot be assumed that there is enough space in the hernial opening for the intestine to push into the abdominal cavity alongside of an incarcerated loop, etc., the author believes that a knuckle of bowel, even though very small, forces its way amid the loops through the hernial opening as a result of peristalsis. The resulting distension produces traction, which continually draws new intestine into the abdominal cavity, whereby the mesentery remains at first in the hernial sac, and only the parts that are next to the intestine enter the abdominal cavity. At times as a result of high grade tympanites the whole mesentery may be pulled out of the hernial opening. The author does not consider as a retrograde incarceration the prolapse of two intestinal loops in which the connecting loop is not injured materially. In cases in which a retrograde incarceration or hernia duplex is suspected, he warns against attempts at reposition.

RUPP.

Laplace, E.: Thrombosis of the Mesentery. *Tr. Internat. Cong. Med.*, Lond., 1913.

By Surg., Gynec. & Obst.

Thrombosis of the mesentery with its uncertain clinical symptoms is due to an infection which results in a thickening of the mesentery and its blood vessels followed by thrombosis and gangrene of the gut. The infection may be local or may have spread from a neighboring focus.

Infection of the febrile or afebrile type is also accountable for the various forms of phlebitis which occur about the external iliac vein and result in the well-known post-operative oedema of the extremities. The infection is uniform on the right and left sides but will manifest itself at first on the left side on account of the fact that the left iliac artery overrides and compresses the left iliac vein.

The afebrile type of infection may likewise be responsible for such thrombosis which, when finally

loosened, results eventually in pulmonary embolism. In order to guard against this subtle form of infection in post-operative treatment of all abdominal cases, a 1-500 solution of citric acid in water should be administered by the Murphy rectal drip method as a prophylactic.

GASTRO-INTESTINAL TRACT

Holland, C. T.: A Method of Obtaining a Radiograph of the Stomach at Any Particular Phase of Its Contraction. *Arch. Röntg. Ray*, 1913, xviii, 98.
By Surg., Gynec. & Obst.

In a single paragraph is described a practical method of obtaining a radiograph of the stomach at any desired phase of its cycle. The phase desired is found by fluoroscopic observation. By this method also is obtained the number of seconds required for the stomach to complete its cycle, which is usually twenty. By observing a stop-watch that is started at any phase we may determine exactly just when the radiograph of that phase should be taken, as it will return at any multiple of twenty seconds.

HOLLIS E. POTTER.

George, A. W.: The Positive Value of the Röntgen Method in the Diagnosis of Gastric and Duodenal Lesions. *Tr. Am. Röntg. Ray Soc.*, Boston, 1913, Oct.
By Surg., Gynec. & Obst.

1. The "positive" or "exact" method of röntgen diagnosis of duodenal ulcer depends upon the adequate demonstration on plates of the anatomical condition of the duodenum. This is opposed to the method of diagnosis by "symptom-complexes" of increased gastric peristalsis, hypermotility, gastric stasis, relaxed pylorus, etc. These complexes are only inferential in their evidence, and never positive.

2. Ninety-five per cent of duodenal ulcers occur in the first portion of the duodenum.

3. The first portion of the duodenum is anatomically a constant entity. Germain examined the duodenums of four hundred cadavers, and found the first portion always constant in shape, contour, and general characteristics, unless actually diseased.

4. If the first portion of the duodenum is normal it can be demonstrated by the bismuth method upon a plate. It will be seen as a cap with a characteristic shape and smooth outline. In every normal case it can always be demonstrated upon plates by using some one of the three positions — prone, standing, or lateral. There is no exception to this rule. Apparent exceptions are due to improper technique, and especially to too much reliance upon the fluoroscopic examination.

5. The constant presence upon a series of plates of a constant defect or abnormality in the cap means positively a pathological condition in the duodenum. This may be due to indurated ulcer, adhesions, gall-bladder disease, spasm, etc., which require a differential diagnosis.

6. Every duodenal ulcer which is more than a simple mucous membrane erosion will deform the contour of the bismuth mass in the cap. This deformity is due not to the minute mucosal defect, but to the much larger callus which involves the submucosal and muscular coats.

7. The demonstration of a normal duodenal cap upon a plate definitely rules out the possibility of indurated or surgical duodenal ulcer.

Outland, J. H., Skinner, E. H., and Clendening, L.: A Study of the Mechanism of the Stomach after Gastro-Enterostomy by Means of the X-Ray. *Surg., Gynec. & Obst.*, 1913, xvii, 175.
By Surg., Gynec. & Obst.

The authors studied the physiology and mechanism of digestion by means of the fluoroscope and the X-ray in six patients upon whom gastro-enterostomy had been performed. They attempted to determine in particular whether, after gastro-enterostomy, the food leaves the stomach by way of the pylorus or the stoma, and the rate at which the stomach is emptied. The examinations were made from three weeks to three years after the operation had been performed.

In all cases it was found that the stomach was drained by the gastro-enterostomy stoma. In four, the food left by the gastro-enterostomy opening exclusively, and in two, by both the stoma and the pylorus. The rate of emptying was reduced.

The conclusions drawn from this study are as follows: (1) Gastro-enterostomy, performed properly, is a drainage operation. (2) After gastro-enterostomy, if the stoma is at the lowest part of the stomach in the erect position, the food leaves the stomach almost exclusively by the gastro-enterostomy opening. (3) Under these conditions the stomach is emptied very rapidly. (4) Gastro-enterostomy should be performed only in cases of pyloric stenosis or pyloric spasm due to duodenal or gastric ulcer. (5) The gastro-enterostomy opening should be large and placed as close as possible to the pyloric antrum. (6) When the gastro-enterostomy opening does not quite drain the stomach, the food leaves by way of both the stoma and the pylorus. Even in these cases, however, the stomach empties itself more rapidly than the normal stomach. (7) Clinical failures after gastro-enterostomy are due probably to faulty implantation of the stoma.

Cole, L. G.: Diagnosis and Differential Diagnosis of Gastro-Duodenal Lesions. *Tr. Am. Röntg. Ray Soc.*, Boston, 1913, Oct.

By Surg., Gynec. & Obst.

Cole claimed that by making several series of röntgenograms of the stomach with the patient in the prone, erect, and lateral positions at various intervals after the ingestion of bismuth and butter-milk, he can make a positive or negative diagnosis of gastric ulcer, indurated ulcer of the stomach, or duodenal ulcer; and that where cholecystitis is associated with adhesions, he can detect the evidences of the adhesions.

His remarks were largely extracts from previous communications based on personal experience in 526 cases. He demonstrated the appearance of the normal "cap" (pilleus ventriculi) and described the physiology of the pylorus as observed röntgenologically and used these normal cases as controls to show the difference between extensive malignant and non-malignant lesions of the stomach.

He recognized his inability to differentiate between early carcinoma and indurated gastric ulcer, but stated that in these cases surgical procedure is indicated regardless of whether the clinical history corroborated the röntgenological findings, and that the lesion should be considered malignant until proven otherwise by microscopical examination of the specimen after its removal. In such a case the surgeon does not know whether he has cured an early carcinoma or prevented one, until he receives the pathological report.

Carcinomas too extensive for removal are readily recognized, and unnecessary surgical procedure may be prevented. Such cases do not require a long series of röntgenograms.

This communication centered around the negative and positive diagnosis of duodenal ulcer or, as the author preferred to call it, post-pyloric ulcer. Cole stated that if a single röntgenogram out of 40 showed a symmetrical "cap" corresponding in contour with the pars pylorica, and if the pyloric sphincter was clear-cut and functionated in a normal manner (previously described), we are justified in making a negative diagnosis of duodenal ulcer of the "cap," 95 per cent of which occur in this portion of the tract.

The positive diagnosis of duodenal ulcer or extensive adhesions from cholecystitis may be made with remarkable accuracy. Ulcers with cicatricial contractions may not always be differentiated from the extensive adhesions usually accompanying cholecystitis. This differentiation, however, is of more scientific interest than practical value because in either condition surgery is indicated if the symptoms are sufficiently characteristic.

The author recognized spasmodic contraction of the "cap" and pylorus caused by lesions at other points in the abdomen, particularly those at or near the cæcum (kinks in the ileum, appendicitis, mobile cæcum, etc.), and stated that care should be exercised to avoid mistaking these spasmodic contractions for organic lesions. Sometimes a confirmatory series of röntgenograms after the administration of belladonna is necessary to differentiate between spasmodic and organic lesions of the "cap" or pylorus.

In conclusion Cole stated that by studying individually and collectively a large series of röntgenograms and matching them over each other, one can make a diagnosis of early carcinoma of the pars pylorica, indurated ulcer of the stomach, and duodenal ulcer with a degree of certainty equal to that with which one recognizes renal calculi by röntgenograms.

The discussion centered around the expense necessitated by serial röntgenography and the relative value of röntgenoscopy and serial röntgenography. The way in which serial röntgenography can be employed among the masses is the same in which surgery is employed, each patient paying according to his means.

The consensus of opinion was that use should be made of both; that where a positive diagnosis (usually of extensive lesion) can be made by röntgenoscopy, serial röntgenography is unnecessary; but that in all doubtful cases serial röntgenography is absolutely essential before one is justified in making a negative diagnosis of gastric or duodenal ulcer or carcinoma.

Pirie, A. H.: Indications Afforded by X-Rays for and against Operations in Diseases of the Stomach and the Results of Such Operations.
Tr. Am. Röntg. Ray. Soc., Boston, 1913, Oct.

By Surg., Gynec. & Obst.

The author gave his experience of cases in which a diagnosis had been established or confirmed by röntgen rays in diseases of the stomach, and cited the results obtained by surgical and medical treatment. He reviewed the following subjects:

1. Chronic gastric ulcer. Slides were shown illustrating the ulcer filled with barium sulphite and with the bubble of gas above the ulcer. Two slides showed the ulcer filled with barium when the rest of the stomach had been emptied. Pirie advocated shutting off the ulcer by tying a band of fascia tightly around the stomach above the ulcer and anastomosing the jejunum to the lowest part of the cardiac end of the stomach.

2. Acute gastric ulcer, indicated by spasm opposite the ulcer and gastric stasis. Operation was not resorted to in such cases.

3. Early carcinoma. The author described cases in which carcinoma had not been suspected on clinical grounds but unremovable carcinomas were found by röntgenograms.

4. Late carcinoma, shown by X-rays to be irremovable.

5. Cardiac stenosis, mistaken for pyloric stenosis prior to X-ray examination.

6. Pyloric stenosis, when due to duodenal ulcer, does not show finger-like indentations such as are present when it is due to carcinoma.

7. Gastropotosis. The patient's symptoms were not relieved by operation and elevation of the stomach. The author advocated gastro-enterostomy, as in all cases in which the food escaped quickly from the stomach he found that the stomach was small and high.

8. Tumors pressing upon the stomach. Slides were shown of distortions of the stomach by pancreatic cyst and enlarged spleen.

9. Adhesions about the stomach and pressure by gas surrounding organs.

10. Normal stomachs, pronounced normal by X-ray examination and found so at operation.

Pirie believes that the röntgenologist should advise the patient not only for or against operation but also in regard to diet and times for eating.

Henle, A.: Experiences in the Surgical Treatment of Benign Affections of the Stomach and Duodenum (Erfahrungen bei chirurgischer Behandlung gutartiger Affektionen des Magens und Duodenums). *Verhandl. d. Gesellsch. deutscher Naturf. u. Ärzte*, 1913, ii, 144.

By Zentralbl. f. d. ges. Chir. u. i. Grenzgeb.

Two cases of tuberculous duodenal stenosis were healed by gastro-enterostomy with Kelling's closure of the pylorus. In both cases the röntgen examination failed inasmuch as it showed in the one case only a pyloric stenosis and in the other a pyloric and a high-grade duodenal stenosis. In ten cases of typical ulcers of the duodenum, pyloric exclusion with separation of the stomach was performed with eight cures. In two cases, ulcer symptoms, i. e., hæmorrhages, reappeared after the operation. In the one these were transitory; in the other a second laparotomy had to be performed five and a half years later. A kink and stenosis of the small intestine by adhesions were found 25 cm. below the gastro-enterostomy, and an ulcer in the latter, which required resection and a new gastro-enterostomy. Exitus. The post-mortem examination showed complete cicatrization of the old ulcer and an atrophy of the various typical gastric glands in the excluded portion of the stomach removed by the resection.

In pyloric exclusion the stomach may be severed in the prepyloric part. In this region the operation can be performed much more easily and without fear that the isolated portion of the stomach will continue to produce hydrochloric acid which would keep the duodenal ulcer open. Possibly recurrences observed soon after operation are due to a temporary continuation of the hydrochloric acid secretion.

Henle has occasionally attempted exclusion also in painful ulcers of the pylorus. This he has done in twenty-four cases, in which there were only four deaths. Two of the deaths, however, were not ascribable to the operation. Simple gastro-enterostomy he has performed in benign gastric affections fifty times with only three deaths. Among these were five gastro-duodenostomies, which Henle would prefer if they were not so difficult to perform through a median incision. In all but two cases a posterior retrocolic gastro-enterostomy was performed. In only two cases this led to the development of a peptic ulcer. Peptic ulcer occurred also in one of the two cases of anterior gastro-enterostomy and required repeated operations for a cure. The author has never attempted a transverse resection in benign gastric affections, but has made wedge-shaped resections and typical pyloric resections in five cases each. Two of the former patients died and all of the latter were cured.

The author concludes that in gastric diseases that are undoubtedly benign the operations should be those that give the most favorable prognosis.

In the discussion following Henle's paper, Schmieden stated that simple ligation with additional sutures over the pylorus lead again later to permeability; that the radiological diagnosis of duodenal ulcer is difficult; and that peptic ulcer occurs almost exclusively in anterior gastro-enterostomy. In hour-glass stomach a transverse resection is indicated. In solitary ulcers far from the pylorus a simple gastro-enterostomy is insufficient. Roepke recommended in pyloric exclusion, the separation of the stomach rather far proximally. He prefers a transverse rather than a partial resection. In post-operative hæmorrhage he has employed successfully the injection of 20 ccm. of diphtheria serum with the addition of one injection of secacornin. Dreesmann has determined experimentally that a thread tightly knotted around the pylorus gives a permanent closure. Excised ulcers of the lesser curvature he sutures in a longitudinal direction, thereby avoiding a kinking of the stomach.

BRENTANO.

Einhorn, M.: Indications for Duodenal Alimentation (Indikationen für die Duodenalernährungs-methode). *Deutsche med. Wchnschr.*, 1913, xxxix, 1404. By Zentralbl. f. d. ges. Chir. u. i. Grenzgeb.

By duodenal feeding is understood the nutrition of a patient while the stomach remains empty. This is made possible by introducing into the stomach a small rubber tube, which then enters the duodenum. In a normal person it requires from two to three hours for the beginning of the sound to reach the duodenum. In patients with pylorospasm a longer time is necessary. Thirty-six hours is the longest time observed by Einhorn. Nourishment is given every two hours (8 times a day) and consists chiefly of milk, eggs, and one teaspoonful of lactose. One to two teaspoonsful of butter may be added to every second meal.

The author at first used an irrigator to inject the nutritive fluid, but now uses a syringe with a triple stopcock. As a test to determine whether the sound has reached the duodenum, the fluid is sucked up out of the sound. If the fluid comes from the stomach it is acid, if from the duodenum it is alkaline. A colored fluid may be given by mouth to find out if it can be aspirated through the sound. The nutritive fluid should always be at body temperature. As the sound must remain in place a long time, it is important to clean it after every feeding with water and air to prevent obstruction. In addition to the food, Einhorn introduces about one liter of physiological salt solution daily.

In the last three and a half years the author has used duodenal alimentation in eighty-four patients, in each on an average of from ten to fifteen days. The indications for this method of treatment are: (1) Ulceration of the stomach and duodenum; (2) gastric dilatation without organic obstruction, marked atony with and without pylorospasm; (3) nervous vomiting and the vomiting of pregnancy; (4) diseases of the liver, to limit the blood supply to the

portal vein; and (5) inoperable carcinoma of the stomach and cardia without stenosis. KOLB.

Paterson, H. J.: The Physiology of Gastro-Jejunostomy. *Tr. Internat. Cong. Med.*, Lond., 1913, Aug. By Surg., Gynec. & Obst.

The prevailing view is that gastro-jejunostomy is a drainage operation. Paterson gives reasons why it should be regarded as a physiological operation.

Bile and pancreatic juice are present in the stomach almost invariably after gastro-jejunostomy.

The evidence of this is, that there is an almost constant increase in the mineral chlorides of the gastric contents after gastro-jejunostomy (99 per cent of the author's cases).

This occurs although there is, as a rule (75 per cent of the author's cases), a diminution of the total chlorides.

After undoing a gastro-jejunostomy this increase in the mineral chlorides disappears again.

Illustrative case No. 1, gastric analysis.

Before gastro-jejunostomy.

Total chlorides.....	0.420
Free HCl.....	0.051
Protein HCl.....	0.289
Mineral chlorides.....	0.080

After gastro-jejunostomy.

Total chlorides.....	0.365
Free HCl.....	0.000
Protein HCl.....	0.153
Mineral chlorides.....	0.211

After the gastro-jejunostomy was undone.

Total chlorides.....	0.343
Free HCl.....	0.018
Protein HCl.....	0.270
Mineral chlorides.....	0.055

If an entero-anastomosis is performed as well as gastro-jejunostomy, this increase in the mineral chlorides is not observed.

Illustrative case No. 2, gastric analysis.

Before gastro-jejunostomy.

Total chlorides.....	0.335
Free HCl.....	0.003
Protein HCl.....	0.175
Mineral chlorides.....	0.156

After gastro-jejunostomy and entero-anastomosis.

Total chlorides.....	0.350
Free HCl.....	0.000
Protein HCl.....	0.226
Mineral chlorides.....	0.124

This increase in the mineral chlorides does not occur as a rule after other operations, *e. g.*, after appendectomy. Therefore the inference is that it is due to the entrance of bile and pancreatic juice into the stomach through the anastomotic opening.

The average increase in the mineral chlorides in the author's cases is 0.077 per cent.

Bile and pancreatic juice contain about 0.4 per cent of sodium chloride; therefore, after gastro-jejunostomy the gastric contents contain less than 10 per cent of bile and pancreatic juice, the amount of bile being less than 5 per cent.

Effect of gastro-jejunostomy on gastric secretion: The total acidity is lowered, the average diminution being 30 per cent. This is due partly to neutralisation by bile and pancreatic juice and partly to diminished secretion.

Effect of gastro-jejunostomy on the motility of the stomach: In the absence of pyloric stenosis, gastro-jejunostomy slightly hastens evacuation of the stomach, but the acceleration is not sufficient to account for the beneficial effects of the operation. This is against the view that gastro-jejunostomy is a drainage operation.

Effect of gastro-jejunostomy on gastric digestion: Gastric digestion is impaired but not lost after gastro-jejunostomy. The impairment seems to be due to loss of free hydrochloric acid.

A report is given of observations made upon patients that were placed upon Schmidt's diet after gastro-jejunostomy, and of observations obtained with the red carmine fibrin test.

Effect of gastro-jejunostomy on metabolism of human body: Gastro-jejunostomy has no material effect on the metabolism of the human body. The investigations of Harley and Goodbody on the metabolism of healthy individuals gave the following results:

	Per Cent of Intake
Highest absorption of nitrogen.....	97.0
Lowest absorption of nitrogen.....	90.1
Average (75 cases).....	93.46
Highest absorption of fat.....	98.5
Lowest absorption of fat.....	90.1
Average (79 cases).....	95.05

In twelve patients on whom gastro-jejunostomy had been performed, the author found that in every instance the amounts of nitrogen and fat absorbed were within these limits.

Conclusions:

1. A certain amount (less than 10 per cent) of bile and pancreatic juice enters the stomach after gastro-jejunostomy.

2. The total acidity of the gastric contents is diminished, on an average, by 30 per cent. This is due partly to neutralisation of free hydrochloric acid by bile and pancreatic juice, and partly to earlier stimulation of the pancreatic secretion and compensatory earlier lessening of the gastric secretion.

3. Gastric digestion is impaired, but not lost, after gastro-jejunostomy.

4. The motility of the stomach, if there be no pyloric stenosis, is for practical purposes unaffected by gastro-jejunostomy.

5. Gastro-jejunostomy has no material effect on the absorption of nitrogen and fat. This chemico-pathological evidence is supported by the evidence of clinical experience.

The author concludes that gastro-jejunostomy is a physiological, and not a mechanical operation. Probably the most important result of this operation is that bile and pancreatic juice in small quantity gain entrance to the stomach.

Practical lessons:

1. Occlusion of the pylorus is an unnecessary complication of gastro-jejunostomy.

2. Excision of simple ulcers is unnecessary if gastro-jejunostomy be a physiological operation.

The view that malignant degeneration of gastric ulcers is frequent after gastro-jejunostomy, is contrary to clinical experience.

Eastman, J. R.: Foetal Peritoneal Folds and Their Relation to Postnatal Chronic and Acute Occlusions of the Large and Small Intestine.
J. Am. M. Ass., 1913, lxi, 635.

By Surg., Gynec. & Obst.

The author describes several peritoneal foetal folds of fairly constant form and distribution and shows their latent possibilities in regard to occlusions of the large and small intestine.

The position and attachments of certain of these folds suggest that they may be causative factors in gravitations and angulations of the terminal ileum. The genito-mesenteric fold of Reid, which passes from the mesentery of the terminal ileum down into the pelvis to the genital gland, for example, bears an interesting resemblance to the ileopelvic band in the adult which Lane believes is one of the chief causes of a downward kink in the ileum.

As Reid's fold is continuous above with the duodenorenal ligament, it is possible that, by contracting, it may cause an upward kinking of the terminal ileum. This may be true also of the rather constant ileocolic folds and the so-called root folds.

The author found Reid's fold in fourteen of thirty-two foetuses and also in the adult. He suggests that Lane's ileopelvic band and Reid's fold are identical and that it may have been formed by the dragging down of the dorsal peritoneum in the descent of the right ovary or testis.

In regard to the bloodless fold of Treves, Eastman states that there is considerable evidence to show that this fold begins as an adhesion between the cæcal head and the mural peritoneum, and that at the time of cæcal torsion the serosa of the peritoneum of the lateral abdominal wall is drawn over the caput to form a pocket-like fossa containing the caput and the appendix. The pericolic fold is formed by a similar fusion and torsion at a higher level of the ascending colon.

Another rather common fold that may bind down the cæcum and the appendix is described as being of a skirt-like form. It passes from the terminal ileum above, downwards around the basal half of the appendix, and then upwards to inblend with the serosa of the caput.

The adhesions of the colon to the peritoneum of its own mesentery also are believed to be persistent foetal adhesions.

The article is closed with the report of the author's case in which an extensive formation of pericæcal membrane led to an acute and complete obstruction of the ascending colon. The division of the membrane resulted in recovery. PHILLIPS M. CHASE.

Summers, J. E.: Surgical Aspects of Intestinal Stasis from an Anatomic Point of View. *J. Am. M. Ass.*, 1913, lxi, 639.

By Surg., Gynec. & Obst.

The author concludes from his experience, that the membranes of the pericolic type of Jackson may be found in every abdomen either on the right side or in the lower left quadrant; that the symptoms, as a rule, are produced in adults, and appear usually after the fiftieth year of age; and that as up to the time of the beginning of the symptoms, there is never any sign of anything wrong that can be attributed to the membranes, the latter should be regarded, on the whole, as purposive and not offensive. He further states that while these membranes may become offensive early, they should be considered as congenital defects the same as a cleft palate or extra toes. They may also become restrictive instead of conservative, owing to continued abuse of the cæcum and colon with resulting loss of tone. When subsequent symptoms cannot be relieved by treatment, the case should become surgical.

The operation of Monprofit and its recommendation are discussed, with reference to eight cases operated upon by the author. Summers recommends also in the ptoses of the transverse colon the technique of Coffey.

He advises releasing these congenital membranes when they are restrictive. As a rule this should be done at their loosest line of attachment. In other cases that require greater mobility of the colon, however, it should be done at the line of attachment of the pericolic membrane and parietal peritoneum which invariably appears as a white line when tension is made on the viscus in the direction of the fibres and blood vessels.

PHILLIPS M. CHASE.

Tichomiroff, I. A.: Inflammatory Diverticula of the Appendix (Zur Frage der entzündlichen Divertikel des Wurmfortsatzes). *Vrach. Gaz.*, 1913, xx, 613. By Zentralbl. f. d. ges. Chir. u. i. Grenzgeb.

The author reports cases in which, during appendectomy, there were found typical diverticula of the appendix, formed from the mucous membrane that bulged through a defect in the muscularis. In one case the site of the perforation of the diverticulum could be demonstrated; in the other the mucosa was markedly atrophic and thin. The wall of the appendix showed very marked inflammatory changes. In both cases an increased intra-appendicular pressure was indicated; in one case the lumen instead of being slit-like was plainly dilated and the whole mucosa was thinned; in another case there was extensive atrophy of the mucosa. After a searching examination of the literature and on the basis of his own observations the author assumes that the diverticula in the given cases developed from an inflammatory basis as the result of a circumscribed lesion of the muscular wall and additional increased pressure in the appendix. He regards diverticula as of considerable clinical significance because there can readily be retained in them mucus and bacteria

which may cause a recurrent acute inflammatory process, and further, because diverticula tend to perforation. Finally, the author points out the fact that pseudomyxoma of the peritoneum may be caused not only by rupture of ovarian cysts, as formerly supposed, but also by rupture of cysts and diverticula of the appendix.

VON HOLST.

Körte, W.: The Operative Treatment of Malignant Diseases of the Large Intestine, Excluding the Rectum (Die operative Behandlung der malignen Dickdarmgeschwülste, ausschliesslich des Rectums). *Tr. Internat. Cong. Med.*, Lond., 1913, Aug.

By Surg., Gynec. & Obst.

The author based his paper upon his own material, 254 cases in all, and the reports that have been published in the literature since 1900.

The mortality of the radical operation is still quite considerable, amounting to 757 cases in the literature, or 32.2 per cent. The 83 radical operations performed by Körte since 1900 yielded a mortality of 28.9 per cent. The mortality figures of the last decade show somewhat better results.

The particular dangers arise from collapse and peritonitis, and at times are caused by the peculiar anatomical conditions of the large intestine and the difficulties that arise from the intestinal contents.

Acute occlusion of the intestine is a very frequent complication of tumor of the large intestine, occurring in about 38 per cent of the cases. In this condition the attempt must first be made to evacuate the intestine (cæcostomy or colostomy). The radical operation should be secondary (a several-stage operation).

Given sufficient evacuation of the bowels, good blood supply of the extremities of the intestine, and the possibility of approximating them without stretching them, reposition and suture in one stage is the best procedure.

The various anatomical conditions of the different parts of the large intestine demand correspondingly different methods of operation. The prognosis for permanent cure in cases of carcinoma of the large intestine is relatively favorable. Körte reports cures lasting from three years to twenty-one years in 27.7 per cent of the cases of radical operations, or in 39 per cent of the survivors.

Of the palliative operations, antero-anastomosis is the best method in the absence of intestinal occlusion. Cæcostomy or colostomy is the first method for cases of intestinal obstruction. Radical operations (colectomy or entero-anastomosis) must be secondary and should be performed only after the intestine has been evacuated.

Case, J. T.: X-Ray Observations on Colonic Peristalsis and Antiperistalsis with Special Reference to the Ileocolic Valve. *Tr. Internat. Cong. Med.*, Lond., 1913, Aug.

By Surg., Gynec. & Obst.

The author bases his study on the examination of 1500 cases following the ingestion of a bismuth meal.

Antiperistalsis was observed in thirty-seven. In most instances, anti-peristaltic waves originate in the transverse colon near the hepatic flexure, proceed toward the cæcum, and disappear usually at a point that corresponds approximately to the ileocolic junction. Antiperistalsis has been seen also in the descending colon, especially in cases of chronic and acute obstruction of the bowel.

The author's observations have convinced him of the presence of a tonic contraction ring in the right half of the transverse colon, as claimed by Cannon on the basis of results obtained in experiments on animals. The exact location of this tonic ring varies with the tonicity of the proximal colon, but it is usually at a point near the middle of the right half of the transverse colon.

The writer again calls attention to a phenomenon that has been previously described by him as a sign of serious bowel obstruction, viz., *exaggerated antiperistalsis*. He has noted exaggerated antiperistalsis in every case of carcinoma of the colon that he has studied. In such instances it occurred in all parts of the colon. It has been recognized besides in spastic constipation and benign obstructions of the bowel. Also, in every case studied by the author in which ileosigmoidostomy had been performed, retrograde peristalsis was observed in the left half of the colon after the operation.

Case studied also mass peristalsis waves. These were first described by Holzknecht who reported two observations. During the last sixteen months the author has noted movements of this type in thirty-seven patients. The bowel contents suddenly lost their haustral markings and were formed into an ovoid, sausage-shaped mass which had perfectly smooth edges and was rounded at the ends. This mass traveled slowly at about twice the rate of the peristaltic waves in the stomach. The distance traversed varied from three or four inches to several feet. After coming to rest, the mass regained its haustral markings. The time for their reappearance depended upon the consistency of the bowel contents, being brief if the contents were semi-fluid and longer if they were of a firmer consistency.

The effects of massage, mechanical vibration, and electrical stimulation on the peristalsis of the colon were also studied in a number of cases. The immediate effects observed were a deepening of the haustral contractions and sometimes the appearance of antiperistaltic waves. The author concludes that the well-recognized favorable influence of massage and mechanical vibration upon the motility of the bowel must be produced indirectly by increasing the tone of the bowel muscle rather than by any actual mechanical pressure of the bowel contents onward. In order to produce any true electrical stimulation of the bowel wall, a bipolar electrode must be employed.

Special attention was given to the study of the function of the ileocolic valve on the theory that our present knowledge of the antiperistaltic function of the colon demands all the more a recognition of the

normal competency of the ileocolic valve. In the 1500 cases above referred to, incompetency of the ileocolic valve was noted in nearly 250 instances, or once in six. Such a large proportion of incompetent ileocolic valves is explained by the fact that the 1500 cases were gastro-intestinal cases submitted for bismuth-meal study.

The author states that the old idea that insufficiency of the ileocolic valve causes diarrhoea is erroneous. In most cases of insufficiency of the valve the opposite condition, i. e., constipation, prevailed. The fact that ileal stasis and constipation rather than hypermotility is noted when reflux from the colon into the ileum is no longer prevented by a competent ileocolic valve, is explained by our knowledge of antiperistaltic phenomena in the colon.

While it is generally recognized that rectal alimentionation is, on the whole, unsatisfactory, there are enough cases in which it has been successful to warrant the continuance of it.

Körbl, H.: Continence of the Bowel after Radical Operation for Carcinoma of the Rectum (Die Kontinenzverhältnisse nach den radikalen Operationen des Mastdarmkrebses). *Arch. f. klin. Chir.*, 1913, ci, 449. By Zentralbl. f. d. ges. Chir. u. i. Grenzgeb.

Körbl discusses continence of the bowel on the basis of data collected in two hundred and four cases of extirpation of the rectum in von Eiselsberg's clinic. He divides these cases as follows:

I. Cases in which the sphincter was sacrificed. *a.* In one a plastic operation according to Schoemaker was attempted to form a new sphincter. The result seemed good at first, but at the end of two years there was incontinence for liquid stools. *b.* Anus sacralis according to Hochenegg; i. e., a deflection of the bowel to the right and fixation beneath the resected sacrum. Only after six months, and usually after a longer period, did sensation slowly return, and its improvement consumed an equal period of time. With the increasing sensibility the patient could tell when there was to be a movement. At the same time an ampulla usually developed. Among the thirty cases in which the late results were studied there were eight in which sensibility had been lost permanently. These were, almost without exception, cases in which, as the result of gangrene, there had occurred a retraction of the oral end of the gut followed by a healing by granulation tissue. These patients did not have premonition and therefore suffered incontinence. In sixteen cases sensibility was restored and there was no incontinence for formed stools. On a well-regulated diet about one half of these patients were quite comfortable. *c.* Anus sacralis according to Gersuny with late results in seventeen cases. Until the end of a year the spiral formation could be easily felt, and although only slight sensibility had returned, premonition was present and there was no incontinence for formed stools. After two to three years the spiral formation was present only in a few cases. In the others, circular folds and ampullæ had taken its place. Sensi-

bility was finally restored in all cases and there was premonition for movements. Of ten cases examined after a period of three years only one showed the spiral formation, with no incontinence to speak of, even of liquid fæces. Seven had well-developed folds and ampullæ. Sensibility and premonition were fully restored for formed stools. For the restoration of these two functions Gersuny's operation is preferable to Hochenegg's as the peristalsis of the large bowel is felt more intensely. The twisting according to Gersuny, therefore, has an advantage over the single anus formation.

II. Cases in which the sphincter was spared. Except for a few intrarectal excisions and operations by the invagination method, the procedures employed were as follows: *a.* The method of excision after Hochenegg was used in two cases. The results were not very good. There was a high mortality from infection. Good functional results were obtained in thirty-six per cent of the cases. Hochenegg's method favors the occurrence of gangrene. The danger can be minimized by incising the sphincter longitudinally according to the method of Heinecke, but this procedure interferes with the functional result. The author claims that this method is indicated only when the operation must be performed speedily and when only the anal mucous membrane can be spared. *b.* Circular suture, primary or secondary, was employed in thirty-four cases, with a lower mortality and no incontinence in sixty-six per cent of the cases. The author considers this the method of choice in resection of the rectum. The posterior line of suture may be supported by a plastic skin flap after Rotter. To lessen the number of poor results the method should be used only primarily under absolutely favorable conditions. Otherwise the suture of the anterior part of the circumference should be completed and the posterior part fixed to the skin to produce a favorable condition for secondary suture. *c.* Sigmoidoprostomy after Hochenegg and Eiselsberg (Krogus) was performed as an emergency operation in three cases. This the author considers the method of choice when a long loop of sigmoid can be drawn down easily. *d.* Combined operation was performed in sixteen cases with thirty-seven per cent mortality.

The objection that the more radical procedures interfere too much with voluntary control to be performed extensively the author refutes on the basis of the end-results in his own cases and of those collected from the literature.

HELLER.

Lenk, R., and Eisler, F.: Experimental Radiological Studies on the Physiology and Pathology of the Alimentary Tract (Experimentelle-radiologische Studien zur Physiologie und Pathologie des Verdauungstraktes). *München. med. Wchnschr.* 1913, lx, 1031.

By Zentralbl. f. d. ges. Chir. u. i. Grenzgeb.

The authors report the results of experiments carried out on animals for the radiological study of

the stomach. In contrast to their observations on the normal stomach they found that in hypacidity the peristalsis is stronger and the emptying of the stomach is more rapid; in hyperacidity, on the other hand, there was no deviation from the normal (which fact contradicts the prevailing belief). Motor disturbances in gastric diseases, therefore, have no apparent connection with the chemism of the stomach. This view is confirmed also by comparative observations on human beings. BODE.

Carman, R. D.: The Technique of Röntgen-Ray Examination of the Gastro-Intestinal Tract, and the Interpretation of Screen and Plate Findings. *J. Am. M. Ass.*, 1913, lxi, 321.

By Surg., Gynec. & Obst.

The technique of bismuth X-ray work on the stomach and colon used by the author at the Mayo clinic is described in some detail. Both fluoroscopic and plate methods are used. No marked preference is given to either one as the information obtained by each is somewhat different in character. These methods, therefore, are not in competition and both are used in routine in every case. Most of the data, however, is obtained during the screen examination, two or more subsequent plates acting as a check-up for confirming or amplifying the data previously obtained. Haudek's double meal is given.

The mixtures used for ingestion and injection, and the purpose of each, the general outlay of instruments and the method of using them, and the manner of recording observations are all described.

Printed forms are used for all records which contain in classified form all conditions commonly seen as well as spaces for unusual data and conclusions. The recapitulation sheets contain the diagnostic points boiled down. In this way complete permanent data can be preserved for future reference and comparison.

Points of diagnostic significance are sifted out and the combination may be strong enough and characteristic enough to point to a single diagnosis. Experience in radiology is gradually formulating X-ray "sign complexes" which are analogous to the symptom complexes in ordinary clinical use. The X-ray findings in a given case are diagnostic of one or another lesion in proportion to their coincidence with the known sign complex of that lesion. In one case the X-ray results alone may be diagnostic, while in another, abnormal X-ray findings may be quite lacking.

In arriving at a diagnosis, therefore, it is necessary to consider X-ray findings as supplemental and contributory to other methods.

Quoting from the author: "Visualization of a cancer of the stomach with obvious filling defects, or a gastric ulcer with a characteristic incisura or a niche is so dramatic that the exuberant enthusiasm thus aroused has unfortunately created the impression in some quarters that the Röntgen-ray is ready to supersede the ordinary clinical methods of diagnosis. This impression should be discouraged,

for in the vast majority of instances the ray is only a link in the chain. The X-ray is not a rival of clinical methods, but a most valuable adjunct thereto, and worthy of routine employment."

HOLLIS E. POTTER.

LIVER, PANCREAS, AND SPLEEN

Parlavecchio, G.: A Rare Case of Hydatid Cyst of the Pancreas Cured by Marsupialization (Un cas rarissime d'hydatyde du pancréas guéri par la marsupialisation). *Pensiero méd.*, 1913, No. 25.

By Journal de Chirurgie.

Echinococcus cysts of the pancreas are very rare. Hanser, in 1912, could find only twenty-eight cases in the literature, even counting the doubtful ones. Only eight of these were operated on. All were cured. In one case the pericystium was extirpated; in another Bobroff's method was used; i. e., incision, extraction of the parasitic cyst, injection of an indifferent fluid into the pericystium, and suture; in three cases resection of the pericystium, and in five others marsupialization.

The author's patient was a woman twenty-five years of age. For eighteen months she had experienced a sense of heaviness and tension in the epigastric region; her appetite was poor; she was constipated, but had neither vomiting, icterus, diarrhoea or melæna. She grew thin, and at the end of eight months had an epigastric tumor as large as an orange, which was diagnosed as cyst of the mesentery.

On examination there was found a prominence in the supra-umbilical region, a little to the left side. This was moved slightly by respiration. Palpation showed a hard, elastic, spherical tumor on the posterior wall of the abdomen, which could be moved slightly both vertically and horizontally. Percussion showed the stomach above it and intestinal tympany below and on the sides. There were no ascites or other objective signs. A diagnosis was made of cystic tumor situated between the two folds of the transverse mesocolon.

On laparotomy a tumor was found between the stomach and transverse colon, behind the gastrocolic omentum. As it was very adherent on all sides, the idea of extirpating it was given up. It was fixed to the abdominal wall by a run of sutures and opened in the center. About a quart of fluid and daughter vesicles came out. The body of the cyst was firmly implanted on the tail of the pancreas. Complete recovery resulted and was found to be permanent after nine years.

AMEVILLE.

Norrlin, L.: Subcutaneous Traumatic Rupture of the Spleen and Its Treatment (Über subcutane, traumatische Milzrupturen und ihre Behandlung). *Upsala Läkaref. Förh.*, N. F., 1913, xviii, 214. By Zentralbl. f. d. ges. Chir. u. i. Grenzgeb.

Among 33,000 patients received in the surgical section of the Sahlgren Hospital in Gotenburg from 1891 to 1912, there were 36 cases of subcutaneous

injury of the abdominal viscera, 5 of which were injuries of the spleen. During the same period of time there were 8,700 cases of injury treated at this hospital. Injuries to the spleen, therefore, occurred only once in 1,740 cases of accidental injury and once in every 9 cases of rupture of the abdominal organs.

In four other Swedish hospitals the author has discovered eight additional unpublished cases of rupture of the spleen, making in all thirteen cases. Eleven of these were males. The youngest patient was seven years of age and the oldest sixty-seven. Most of them, however, were children about ten years old and men from twenty to forty years.

One patient who had a fixed and enlarged spleen ruptured it during an epileptic fit and died within fifteen minutes. All of the others had been subjected to severe violence, generally upon the left side. In no case was there a history of typhoid or malaria. In four cases the condition of the spleen was pathological; in three it was moderately enlarged (once being complicated by Laënnec's cirrhosis of the liver) and in one it weighed 1200 grams (Banti's disease?). In three cases, besides rupture of the capsule and medulla, there was subcapsular hæmorrhage; in six, single or multiple partial rupture of the capsule and medulla, and in four the spleen was completely, or almost completely, broken into two or more pieces. In four cases the rupture was uncomplicated; once it was complicated by rupture of the liver and the ventricles; once by rupture of the small and large intestines; once by rupture of the diaphragm; once by rupture of the splenic vein; once by rupture of the lung and fracture of the ribs, and four times by fracture of the ribs alone.

The author believes that complicating rib fracture is probably much more frequent than is shown by these and other statistics. Pain in the left scapula or shoulder was not noticed in any case. As a rule there were no outward signs of injury. Three patients died immediately after the injury. One of the ten operated upon died. In this case there was also rupture of the liver. The remaining nine recovered after an average time of thirty-two days. The ribs were not resected in any of the cases. Incisions were made as follows: once a simple horizontal incision under the left costal margin, once a median incision, once a vertical incision through the middle part of the sheath of the right rectus, once a similar incision on the left side, and five times a T incision. Tamponing was successful in two cases and failed in one. In another case where the tampon was used the hæmorrhage continued, and the next day it was necessary to perform a splenectomy. Partial splenectomy was performed twice with good results, one third to one half of the spleen being removed. Total splenectomy was performed in five cases. On examination two to nine months after the operation no evidence of any bad effect was found. In agreement with Stinelli, the author advises an attempt at conservative treatment by compressing the vessels of the hilus.

Norrin sums up his conclusions as follows:

The number of cases of rupture of the spleen brought to the hospitals in time for operation seems to be increasing. Therefore every surgeon should familiarize himself with the symptoms and treatment of this condition. There are no pathognomonic symptoms but it is possible to make a probable diagnosis. The preferred incision is an exploratory incision from which a transverse incision is made through the left rectus muscle. The spleen should be preserved if possible. Future surgical progress should be in the direction of developing conservative methods.

GIERTZ.

Biach, P., and Weltmann, O.: The Inhibitory Influence of the Spleen upon the Growth of Rat Sarcomata (Über den wachstumshemmenden Einfluss der Milz auf das Rattensarkom). *Wien. klin. Wchnschr.*, 1913, xxvi, 1115.

By Zentralbl. f. d. ges. Chir. u. i. Grenzgeb.

Whenever the authors inoculated sarcomatous tissue mixed with splenic tissue they observed an inhibitory influence exerted by the splenic tissue upon the development of the tumors. The spleens of sarcomatous rats exerted a more powerful inhibitory action than those of healthy animals. The immunity developing in the body following the absorption of the tumor cells is considerably increased by the injection of ground-up splenic tissue. The animals that remained refractive following the injection of splenic and tumor tissue did not develop any tumors following a second inoculation. It is impossible to state what the action of the spleen is in all of these processes. The splenic tissue may increase the natural protective substances of the body or it may exert a destructive influence upon the tumor cells by means of ferments. The injection of the splenic tissue in the rat undoubtedly produces a general reaction of some sort which must be interpreted as increasing the immunizing processes resulting from the growth of the tumor cells.

CARL LEWIN.

Polenoff, A., and Ladygin, M.: The Hæmostatic Action of Fatty Tissue in Injuries of Parenchymatous Organs of the Abdomen (Die blutstillende Wirkung des Fettgewebes bei Verletzungen parenchymatöser Organe der Bauchhöhle). *Vratch. Gaz.*, St. Petersburg, 1913, xx, 737.

By Zentralbl. f. d. ges. Chir. u. i. Grenzgeb.

Former experiments conducted at the clinic of Oppel and Federoff showed that the hæmostatic action of transplanted tissue depends upon the presence of thrombokinase, and that therefore tissues that are rich in blood vessels and contain much thrombokinase are the best adapted for transplantation. The authors next conducted experiments to determine the hæmostatic action of transplanted fatty tissue. For this purpose injuries were inflicted upon the spleen, kidneys, and liver of rabbits and the wounds sutured over with fatty tissue

or tamponed with fatty tissue. In all cases the bleeding ceased within three to five minutes. All of the animals withstood the operations well. The authors tested the method also on three human patients. One case was a severe subcutaneous rupture of the left kidney with severe hæmorrhage which could not be controlled with the usual methods. A piece of the perirenal fat was therefore transplanted and the hæmorrhage ceased immediately. The patient was discharged cured within two weeks. The other two cases were severe stab wounds of the liver and lung. In both, a piece of subcutaneous fat was transplanted and the hæmorrhages ceased within a short time.

The experiments revealed the fact that fatty tissue has as good a hæmostatic action as other tissues although it contains only a small amount of blood and consequently only a little thrombokinase. It is doubtful, therefore, whether thrombokinase is really the principal factor in the hæmostatic action of transplanted tissue. At the present time the authors are determining the quantity of thrombokinase that is contained in fatty tissue.

VON HOLST.

Fowler, R. S.: The Elevated Head and Trunk Position in the Treatment of Surgical Lesions of the Abdomen. *Tr. Internat. Cong. Med.*, Lond., 1913, Aug.
By Surg., Gynec. & Obst.

This paper is based on the author's observation of over 300 cases of diffuse septic peritonitis and a study of those operated upon by other surgeons.

The explanation of the value of the elevated head and trunk position given by the author is as follows: The peritoneum is an enormous lymph-sac, and inflammation of this membrane is therefore a lymphangitis. The peritoneal absorbents are represented by lymphatics in the structure of the peritoneum. These lymph-channels are large and numerous in the neighborhood of the diaphragm, and have comparatively large openings or stomata; in the intestinal area the lymph-trunks and stomata are less numerous, and in the pelvic area the larger lymph-channels and stomata are absent. In localities where the lymph channels are large, as in the upper abdomen, especially in the diaphragmatic area, absorption occurs before the lymph-channels can be obliterated, and the organism becomes overwhelmed. It follows, then, that if the toxic products can be confined to, or drained into, the lower abdominal or pelvic area, an inflammatory occlusion of the capillary lymphatics will result and absorption will be retarded to a great degree. It is this result that makes the elevated head and trunk positive of value in surgical lesions of the abdomen.

In treating cases of peritoneal involvement, all septic material should first be removed as rapidly and with as little disturbance of the peritoneum as possible. Advantage should be taken of the force of gravity in order to facilitate the passage of fluids from abdominal areas to the pelvis. The latter is accomplished by means of the elevated head and

trunk position and has for its purposes: (1) The lessening of the rapidity of the absorption of septic products by retarding the normal intraperitoneal wave toward the diaphragm. (2) The relief of diaphragmatic pressure and the favoring of normal respiration. (3) The promotion of normal peristalsis, both gastric and intestinal. (4) The localization or prevention of the spread of infective processes in the pelvis.

R. W. MCNEALY.

Carrel, A.: Concerning Visceral Organisms. *J. Exp. Med.*, 1913, xviii, 155.

By Surg., Gynec. & Obst.

Carrel gives an account of his experiments in which he kept animal organs alive and functioning after their removal from the animal body. Abdominal and thoracic viscera removed from cats and

dogs were kept in Ringer's solution at 38 degrees centigrade. The lungs were ventilated artificially. Food and water introduced into the oesophagus were digested. Fæces were excreted from the artificial anus. Urine also was excreted. The heart-beat varied from 120 to 150.

The organisms lived for periods of from three to thirteen and a quarter hours after the death of the animal from which they had been taken. In some instances the death of the organisms occurred rather suddenly. Usually, however, it was preceded by irregularity and weakness of the heart-beat. In some cases the heart-beat was weak after the removal of the organs from the animal body but it became strong immediately after transfusion from another animal of the same species.

JAMES F. CHURCHILL.

SURGERY OF THE EXTREMITIES

DISEASES OF BONES, JOINTS, MUSCLES, ETC. GENERAL CONDITIONS COMMONLY FOUND IN THE EXTREMITIES

Frauenthal, H. W.: Syphilitic Bone and Joint Conditions. *Tr. Internat. Cong. Med.*, Lond., 1913, Aug.

By Surg., Gynec. & Obst.

This paper was presented for the purpose of drawing the attention of the orthopedist to the frequency of bone and joint lesions in inherited and acquired syphilis. These must often be regarded as tubercular, rheumatic, etc., for in the reports of orthopedic institutions, few cases are given.

From a review of the literature published in England and America, the author is convinced that syphilitic joint conditions have not received the consideration to which they are entitled. The observations and statistics of the most eminent continental observers show a much larger percentage of cases. Osler, in one of his recent statements, claimed that 50 per cent of the human race die from either direct or indirect effects of syphilitic infection.

According to Fournier, 39 per cent of all cases of congenital syphilis have joint diseases. Von Hippel states that 56 per cent have arthritis, and Schuller claims that 7 per cent of all joint diseases in children are syphilitic.

To arrive at a correct diagnosis by a system of exclusion, the following points in inherited and acquired syphilis should be taken into account in determining bone and joint syphilis:

1. Blood tests: (1) The finding of the spirocheta pallida; (2) the Wassermann test; and (3) the Noguchi test.

2. Night pain in the bones.

3. X-ray findings in bone and joint conditions: (1) Periosteal thickening; (2) a uniform bone shadow that is a unification of compact and cancellous tissue, first reported by the author in 1906; (3) a process appearing, by contrast, as a light area, and

which is a gummatous destruction of the bone; (4) epiphyseal hypertrophy, detachment, etc.; (5) bone tumors; and (6) bone cysts.

4. Epiphysitis: Syphilitic epiphysitis is characteristic of congenital syphilis, as has been described by Barlow, Fournier, Farrott, and Taylor.

5. Lymphadenitis: General lymphadenitis should excite the suspicion of syphilis.

6. Anti-syphilis treatment: A doubtful diagnosis may be confirmed by a course of anti-syphilis treatment.

Attention is drawn to the fact that a syphilitic hydrops of the joint precedes the eruption both in congenital and acquired syphilis and that syphilitic and tuberculous processes often occur simultaneously in the same lesion, a fact that must be remembered in the differential diagnosis.

The author reports 26 cases of syphilitic bone and joint disease in which mistakes had been made in diagnosis or which presented some peculiar syphilitic condition.

Observers have stated that in congenital syphilis about one half of the cases develop arthritis. In doubtful cases the author advises submitting the patient to a Wassermann or Noguchi blood test, but he has found that in some cases in which a negative Wassermann is obtained a small injection of salvarsan or mercury salts in syphilitic cases will give a positive reaction.

It is pointed out that a tubercular discharge from a joint does not exclude the possibility that syphilis may be the main cause of the joint disturbance, and if the syphilis is treated, the tubercular infection may often be cured.

At the Hospital for Deformities and Joint Diseases there was found in 15 per cent of the cases a tubercular invasion on a syphilitic base. A marked improvement was obtained in these cases by the addition of salvarsan and iodide to the other treatment.

Wachsner, F.: Acute Osteomyelitis and Plastic Operations on Bone in Childhood; from the Material of the Emperor and Empress Friedrich Children's Hospital for the years 1890 to 1912 (Über akute Osteomyelitis und Osteoplastik im Kindesalter, bearbeitet an dem gesamten Material des Kaiser- und Kaiserin-Friedrich-Kinderkrankenhauses in der Zeit seines Bestehens vom Jahre 1890-1912). *Arch. f. Kinderh.*, Stuttg. 1913, lx-lxi, Festschr. f. Adolf. Baginsky, 748.

By Zentralbl. f. d. ges. Chir. u. i. Grenzgeb.

This work is divided into a consideration of osteomyelitis in childhood and a thorough review of Gluck's methods of plastic operation on bone for defects caused by osteomyelitis and similar processes.

The author notes the frequency of streptococcus infection of bones and joints in infancy and the prevalence of mixed infections later. Of the infectious diseases, scarlet fever is the most apt to be followed by osteomyelitis. The infection results from embolus at the points where the bone is particularly rich in blood vessels. Trauma is often a starting point.

The prognosis depends upon the severity of the general symptoms. Prompt limitation of the focus of infection improves the prognosis and lessens the danger of general septicæmia. In children the neighboring joints are frequently involved by metastasis. Suppuration does not always take place, for many beginning inflammations are overcome by the vitality and bactericidal power of the tissues.

The diagnosis is not always easy in early childhood. Violent general symptoms, fever, local pain, doughy swelling around the bone, and efforts to spare the affected limb will be noticed before the röntgen picture shows any changes.

The treatment consists in carefully opening the periosteal abscess. If the general symptoms continue, the bone should be opened without delay. In spite of the early removal of affected bone, more or less extensive necrosis cannot always be prevented. In the 90's Gluck replaced the defect with ivory, and obtained good cosmetic and functional results, as is shown by a great number of röntgen pictures. The results of operations that he performed in 1890 and 1893 have been permanent. The cases in which the whole tibia was replaced by ivory are especially interesting. Even when the permanent replacement of the bone by the ivory was prevented by the formation of fistulæ, however, the ivory served a purpose as a temporary fixation, preventing the sinking-in of the soft tissues of the limb and acting as an irritant to stimulate the formation of new bone.

Pictures are given showing artificial knee-joints and cases of plastic operations with boiled bones, metal rods, and bone from the same individual that grew in very well in spite of previous treatment with bichloride solution.

In conclusion, reports are given of two cases. In one the entire tibia except a small piece of the diaphysis at the upper end was removed. The

astragalus also was resected. The bone was replaced by the shaft of the fibula and an artificial joint formed between it and the calcaneus. A picture taken after fourteen years had elapsed showed a new joint formed between the calcaneus and the fibula which had developed the strength of a normal tibia. In the second case the entire tibia, patella, and astragalus were resected and the tibia replaced by the fibula. After five years not only had the fibula increased decidedly in length and thickness, but new bone had been formed from the fragments of periosteum that remained. SPITZY.

Dachtler, H. W.: Typhoid Periostitis. *Tr. Am. Röntg. Ray Soc.*, Boston, 1913, Oct.

By Surg., Gynec. & Obst.

Dachtler reported cases of chronic periostitis with new bone formation which were first diagnosed as syphilis on the basis of both clinical findings and röntgenograms.

These cases gave negative Wassermans but the tibial nodes were so suggestive that the patients were placed on anti-syphilitic treatment though without benefit.

The author had examined one patient three years previously when the latter was convalescing from typhoid. At that time he undoubtedly had typhoid periostitis according to both clinical and röntgenographical findings and none of the bone changes were present that were found three years later and from which the diagnoses of syphilis were made. Neither mercury or neo-salvarsan improved the patient's condition and it was finally decided to try the effect of typhoid vaccines.

Two cases were treated, one by Levison and another by Daniells. The pain in the legs and the other symptoms disappeared and symptomatically the patients were cured.

Further röntgenograms recently taken show no marked change in the bone picture and the patients report that there has never been any return of the symptoms previously complained of.

In conclusion, the author states that there may be marked similarity in the bone changes of chronic typhoid periostitis and syphilis and careful attention to the clinical history may be necessary to avoid errors in diagnosis.

Talbot, Dodd, and Peterson: Experimental Scorbutus and the Röntgen-Ray Diagnosis of Scorbutus. *Boston M. & S. J.*, 1913, clxix, 232.

By Surg., Gynec. & Obst.

The white line seen in radiographs at the ends of the diaphysis of the long bones has been considered by previous writers to be constant in, and peculiar to, infantile scurvy. This line which is due to a selective increase in calcium deposit at this point has been seen in advance of the clinical or radiological signs of subperiosteal hæmorrhage and persists for months after an apparent cure.

When scorbutus is associated with rickets, radiographs show, in addition to the white line, a

distinct roughening of the ends of the bone shaft as if it were teased out with a needle. Also in certain cases of syphilis a white line has been noted occasionally but it is by no means constant.

Experiments were conducted by the authors to test the constancy and further explain the pathological condition that results in the white line. Guinea pigs and monkeys were used. Fed with oats or bread and water, the younger guinea pigs succumbed before the arrival of clinical scorbutus. The larger pigs survived about forty days, and although a definite white line could be demonstrated radiographically in one or more cases, the epiphyses were rather too well united to correspond to the stage of development seen in infants. On microscopical examination the white line was found to be the seat of a definite increase in the density of the bone.

In a monkey fed on unsweetened condensed milk death occurred in three months. Though unobserved during life, the characteristic white line at the diaphyseal ends was noted in the radiographs taken post mortem.

These experiments confirm those previously reported in that it was possible to produce scorbutus in the guinea pig and monkey, and the condition was accompanied by the radiographical white line that is seen constantly in infantile scorbutus.

Van der Scheer, W. M.: Osteomalacia and Psychosis (Osteomalacie und Psychose). *Arch. f. Psychiatr.*, 1913, 1, 845.

By Zentralbl. f. d. ges. Gynäk. u. Geburtsh. s. d. Grenzgeb.

Osteomalacia is often suggested by the clinical symptoms and microscopical appearance of the bones in osteoporosis. The author examined microscopically the glands with an internal secretion having an influence on the metabolism of the bones; i. e., the thyroid gland, the ovaries, the adrenals, and the hypophysis. He considers osteomalacia a chronic inflammatory process which is produced by definite agents, toxins or bacteria, and which requires a special predisposition. This predisposition exists in a disturbed metabolism which may arise from a functional disturbance of certain glands with an internal secretion.

The author's view explains the frequent occurrence of the disease in pregnant and puerperal and strumous women. Patients with chronic insanity are also much more predisposed to this disease than others. This may be due to the fact that the glands of internal secretion play an important rôle in certain forms of chronic psychoses.

RUHEMANN.

Paus, N.: Bone Cysts, Ostitis Fibrosa and Multiple Exostoses (Knochencysten, Ostitis fibrosa und multiple Exostosen). *Norsk Mag. f. Lægevidensk.*, Christiania, 1913, lxxiv, 634.

By Zentralbl. f. d. ges. Chir. u. i. Grenzgeb.

The author reports a case of bone cyst in the upper half of the humerus of a 17-year-old girl. The cyst

had given no symptoms and was discovered in the röntgenogram taken because the patient sustained a fracture of the upper arm below the surgical neck from a fall. The röntgen picture showed with certainty that it was a cyst and not a sarcoma that was present. The cyst wall was chiseled out anteriorly and the microscopical examination verified the diagnosis. Consolidation occurred in from six to seven weeks. The function of the arm was restored completely. No cysts were demonstrable in other parts of the osseous system.

The author mentions further a case of fibrous osteitis in the uppermost part of the femur in a 31-year-old woman. The röntgen picture showed a considerable swelling on the left side in the trochanter region, which was permeated with hollow spaces. Cavities were seen also in the collum and the caput. The collum formed almost an acute angle with the diaphysis of the femur. The bone in the acetabulum seemed more transparent than normal. The radiogram of the right hip joint showed merely an irregularity in the joint surface of the caput. A case of cartilaginous exostoses is also reported.

NILSEN.

Haas, S. L.: The Regeneration of Bone from Periosteum. *Surg., Gynec. & Obst.*, 1913, xvii, 164.

By Surg., Gynec. & Obst.

In an original experimental work, the author has endeavored to determine the exact role that the periosteum plays in the regeneration of bone. He presents also a short resumé of the literature, and the opinions of the leading investigators along this line.

The author's observations were made in a series of six-two experiments on rabbits, dogs, and cats, which lasted from four to two hundred and forty-nine days. All of the experiments were made upon the ribs, which were treated according to a number of methods. The first experiments showed the normal method of regeneration following a simple subperiosteal resection both when bone elements were left in and when they were entirely removed. In another set of experiments the rib was raised from its periosteal bed and a layer of muscle sewed beneath so as to separate it entirely from the periosteum. Bone always grew in from the angle formed by the raised rib and periosteum.

It cannot be denied that the bone may have had some influence in originating the regenerative process, but it is significant that the regeneration occurred only when the periosteum also was present. Therefore, the author concludes that the periosteum must have acted in some other way than by merely passively directing the distribution of new bone. He ascribes to the periosteum some power, possibly of a chemotactic nature, which determines the direction in which new bone shall grow. In another series of experiments similar to the above but with the addition of blood-clot to the periosteal space, the blood-clot stimulated the periosteum to activity even in the absence of any bone connection.

The author's conclusions are as follows: (1) Periosteum, especially in the presence of blood-clot, has the power to regenerate bone. (2) Regeneration of bone is not dependent solely upon the presence of pre-existing bone. (3) Regeneration of bone was never found unless periosteum was present.

Hartung, A.: Unusual Bone Lesions. *Tr. Am. Röntg. Ray Soc.*, Boston, 1913, Oct.
By Surg., Gynec. & Obst.

Two groups of cases are considered, in both of which there is a more or less generalized involvement of the bone. In one the bone affection practically constitutes the disease; in the other it is a manifestation of a coincident lesion.

Group 1 includes two cases of osteitis fibrosa of the variety first described by Paget in 1877 and commonly known as osteitis deformans. These presented all the usual findings—insidious onset, progressive bony enlargement and deformity, ape-like posture, etc. The X-ray examination revealed a coincident osteoporosis and sclerosis, the fine cancellous markings being replaced by a coarse trabeculation. The skulls were especially distinctive in that they showed a peculiar mottling.

Case 3 of the first group was an example of osteitis fibrosa cystica first described by Von Recklinghausen in 1891, and commonly known as multiple bone cysts. Repeated X-ray examinations showed a large number of localized decalcified areas with the cortex of the bones much thinned and expanded. Some of these had fractured spontaneously, some produced pain and swelling, and others were wholly unsuspected. The case was under observation for over four years and the patient's general health during this time was unimpaired.

The next group of three cases came under the classification of hypertrophic osteo-arthropathy of Marie. Two of them were associated with pulmonary tuberculosis, and the third with chronic jaundice, due probably to Hanot's cirrhosis. All three had the characteristic bilateral enlargements of the wrists and ankles associated with some pain and tenderness. Some of the other joints were likewise affected. The X-ray examination revealed an absence of joint changes but a marked osteoperiosteitis near the ends of the long bones around the joints involved. This was most marked at the metatarsals and carpals, the ulnæ, the radii, the tibiæ, and the fibulæ.

Ely, L. W.: Diseases of Joints and Bone Marrow. *Am. J. Surg.*, 1913, xxviii, 300.
By Surg., Gynec. & Obst.

Ely divides joint conditions into two types. Type I includes those cases that are characterized by inflammation or proliferation of the synovia; Type II, those cases that are characterized by inflammation and degeneration of the synovia, degeneration of the marrow, and resulting hypertrophy of the bone and cartilage.

As representing Type II the author describes a

simple synovitis in which there is no gross pathology and only the synovia is inflamed. The disease shows no tendency to spread and involves only one, or at most, two joints. This is a true arthritis deformans in which the infectious element is very feeble in its manifestation. In this class the author puts non-traumatic synovitis and intermittent hydrops. He differentiates it from the various other forms of synovitis.

Severe multiarticular group. It is pointed out that this group is essentially multiarticular and progressive, and involves various joints in succession. Pathologically this group is a proliferation of the synovia and in most cases, also of the lymphoid marrow, an atrophy of the bone (either rarifying osteitis, or a resorption of calcium salts), and an erosion and destruction of the cartilage which results in subluxations, distortions, and fibrous and bony ankylosis. The onset and the symptoms vary. There is a tendency toward symmetrical involvement of the joints which is more or less characteristic. The small joints of the extremities are most likely to be the first involved. Still's disease is included in this group.

As representing Type II the author groups osteoarthritis and the hypertrophic form of Goldthwaite. In discussing the etiology he states that patients with this type of arthritis often suffer with flatulence and intestinal indigestion. In many cases repeated trauma is probably a factor.

The author believes that the changes are due to degenerative processes in the bone marrow, the deeper layer of the periosteum, and the synovia. The bone and cartilage become hypertrophied. The resulting atrophy of the articular cartilage is due to the growing in of new cartilage and bone beneath. The latter deprive the articular cartilage of its nutrition which it derives from the marrow. The peripheral cartilage becomes hypertrophied, and, either persisting or becoming changed into bone, causes spurs, exostoses, and deformities. When portions of the proliferated cartilage get loose, they give rise to joint mice.

Ely states that constitutional symptoms are not conspicuous and that pain and restriction of function in the affected joint are the chief causes of complaint. The restriction of motion is due to mechanical interference.
J. O. WALLACE.

Ridlon, J.: The Mechanical Treatment of Hip Disease. *Tr. Internat. Cong. Med.*, Lond., 1913, Aug.
By Surg., Gynec. & Obst.

By "hip disease" is meant any chronic inflammation of the hip joint that is not differentiated from tuberculosis, and which, when left untreated, results in a more or less diminished range of motion at the joint, with usually some deformity and frequently a shortened limb.

All cases of hip disease demand mechanical treatment; only a very small percentage demand operative treatment, and for these, mechanical treatment is as essential as for cases not operated upon.

The mechanical treatment falls into three general classes; i.e., plaster of Paris splints (long and short); metal splints for immobilization (of which the Thomas splint is the best type), and traction devices for use in bed and for walking (the Taylor splint).

Some cases require treatment in bed for a time; some patients may walk with crutches or the protecting traction splint, and others, at least during the period of convalescence, may with advantage walk on the limb without crutches.

FRACTURES AND DISLOCATIONS

Dollinger, B.: *The Reposition of Fractured Bones under Local Anæsthesia* (Über die Reposition der Bruchenden in Lokalanästhesie). *Zentralbl. f. Chir.*, 1913, xl, 763.

By *Zentralbl. f. d. ges. Chir. u. i. Grenzgeb.*

The best treatment for recent simple fractures of the extremities is the accurate reposition of the parts under the guidance of röntgen rays, and fixation by means of plaster of Paris splints or the Dollinger bandage. In fourteen cases the author controlled the muscular spasms occurring during the reposition of the fractured bones, by means of local anæsthesia. The anæsthetic was either injected between the ends of the fracture or given by the circular infiltration method. The author prefers the latter as the easier and more expedient. When the first method is employed, 10 to 20 ccm. of a 1 per cent novocaine-suprarenin solution are injected directly between the ends of the fractured bone. The anæsthesia is complete at the end of from five to ten minutes. The author anæsthetized two cases in this manner. He recommends the second method, however, as in the first the injection is very painful, the bone fragments very tender, and the solution, easily missing the nerves on account of local hæmorrhages, may readily enter the lumen of a blood vessel and cause novocaine poisoning.

By means of a thin needle, 10 cm. in length, the author infiltrates the parts from as few points as possible; in fractures of the forearm, from 2 points; in fractures of the leg, from 3 to 4 points; and in fractures of the thigh, from 4 to 5 points. These points are about 6 or 7 cm. above the fracture line. In cases of larger hæmatomata they are 10 or more centimeters above. The injections are made to affect the entire transverse section of the part, first the subcutaneous tissues and then the deeper structures, layer by layer. The anæsthetic solution should always precede the needle point. After from 10 to 15 minutes the anæsthesia is complete, the muscular spasm ceases, and the reposition and bandaging of the limb can be accomplished easily. In this manner the author treated, among other cases, four thigh fractures, and sutured two patellas. When anatomical conditions such as those in fractures of the pelvis, ribs, etc., preclude the use of this method, the injections must be made between the fragments of bones. The author claims priority for the application of the circular infiltration anæsthesia in fractures of the thigh.

SIMON.

Speed, K.: *Juxta-Epiphyseal Sprain and Sprain Fracture of the Lower End of the Radius.*

Surg., Gynec. & Obst., 1913, xvii, 241.

By *Surg., Gynec. & Obst.*

The diagnosis of injuries at the wrist covering juxta-epiphyseal sprains and epiphyseal fracture in children and sprain fractures in adults is difficult. These injuries differ from the Colles fracture, which we have gotten into the habit of calling all fractures of the wrist. Light on the subject of lower radial fractures was sought by skiagraphic study of the closure of the lower radial epiphysis. Starting with a child seven years of age, skiagrams were made of subjects a year apart in age up to a twenty-two-year-old adult. The lower radial epiphysis is the most important because it is there that the greatest growth occurs. Accordingly, its health should be guarded to avoid displacements after sprain and fracture and the development of bacterial activity.

A study of the skiagraphic development of this epiphysis demonstrated its growth and closure. At about the eleventh year the ulnar border of the epiphysis begins to close. The closing process slowly travels across toward the inner side of the radius, and the lower epiphysis becomes thicker and larger. The styloid process takes form about the fourteenth year and at the nineteenth year the epiphysis is found to be closed while the styloid process is still growing. The inner side of the epiphysis is the last to close. After the twentieth or the twenty-first year the styloid assumes adult form. On account of the attachment of the strong wrist ligaments in the epiphyseal area, the latter, which is the last to become ossified and is subject to severe strains incidental to falls on the hands, is the site of cracks and fractures before other portions of the bone. As the hand is more often abducted than pronated, the main stress in falls occurs on the internal ligaments. The ulnar border of the radius is held firmly by the radio-ulnar ligament. The latter resists and the styloid process gives first. The median edge of the epiphysis, closing last, leaves a weaker spot here to favor this result. The pronator quadratus muscle, acting above, tends to pull over the upper part of the radius and to approximate it to the ulna and thus gives additional counterpull to the tearing-out force of the internal lateral ligament.

The capsular ligament of the wrist is continuous with the periosteum of the radius, and juxta-epiphyseal sprain, with tearing of these structures, causes symptoms as acute as those resulting from epiphyseal or sprain fracture. In sprain, the swelling and effusion of blood are deferred. In this it simulates fracture, which is but a further action of an identical force. As a rule, if the capsule tears or gives way, the bone does not break. The ligament, however, is stronger than the bone or periosteum, and in the majority of tests on the cadaver pulls out the bone surface, or causes by its line of stress a sprain fracture extending obliquely with no displacement across the epiphyseal area. The mechan-

ism of this type of fracture seems to be divided into the following three stages: (1) a splitting or crushing by the force from the carpal bones; (2) the yielding of the radius at the weak point — i. e., in the vicinity of an old, or present, epiphyseal line — by the breaking up of the causative force; and (3) a cross-strain at the insertion of the capsular ligaments, especially on the anterior aspect with the hand in dorsal hyperextension.

Diagnostic signs of fracture are: (1) a history of sufficient trauma, and (2) a small, sharply localized area of swelling and acute tenderness over the attachment of the ligaments at the lower end of the radius. These findings are pronounced and recur always at the same place when the test is repeated.

Troell, A.: The Treatment of Fractures of the Radius (Über die Behandlung der Radiusbrüche). *Allm. Sven. Läkartidn.*, Stockholm, 1913, x, 577.
By Zentralbl. f. d. ges. Chir. u. i. Grenzgeb.

The author reports two hundred and six cases of typical fracture of the radius which he treated in the polyclinic in Stockholm in 1911. Usually in simple cases of this kind he replaces the bone at the first sitting without anæsthetization. The correctness of the position is determined by two röntgen photographs. If there is no displacement of the fragments, fixation is not undertaken. In eleven cases a plaster of Paris cast was used, in six the patient being under the influence of an anæsthetic. Five patients were children of not more than twelve years of age. The results were as follows:

In four cases there was perfect anatomical restoration; in one, somewhat faulty configuration of the bone, in one, slight lateral displacement with diminished function, and in seven, normal function.

In one hundred and eighteen cases fixation was obtained with a dorsal splint. In twelve cases at the end of treatment there was complete anatomical and functional recovery. Of the remaining cases examined later recovery was complete in thirty cases and incomplete in forty.

Because of these poor results, the author tried Lexer's bandage. He found, however, that he could not keep it in place. Accordingly he changed to an adhesive bandage, applied according to the same principles as Lexer's bandage. Details are given in regard to the manner in which the adhesive plaster strips were applied. Over these strips Troell placed a Lexer's bandage with cotton wool padding. With this method fixation failed in only one case. Usually the adhesive bandage is worn two and one half weeks. In seven cases there was complete anatomical and functional recovery.

On later examination marked deformity was found in only one case out of twenty-eight. The functional result was good except in a few cases. Three cases suffered injury from the adhesive bandage, pressure necrosis or pustulated eczema. In one case there was prominent palmar flexion with subluxation. The adhesive bandage may cause over-correction.

GIERTZ.

Armstrong, G. E.: Fracture of the Femur. *Tr. Internat. Cong. Med.*, Lond., 1913, Aug.
By Surg., Gynec. & Obst.

The points made by the author were as follows:

1. As clearly established by the Committee of the British Medical Association, the functional result is dependent largely upon the anatomical result. In a considerable proportion of fractures of the shaft of the femur it is impossible by traction and manipulation to secure perfect replacement of the fragments and to retain them in good position. In all cases in which this cannot be accomplished the fragments should be replaced through an incision and retained by a suitable Lane plate. To avoid subsequent misunderstandings the following routine procedure was recommended: The presence of a fracture and the number, position, and shape of the fragments should be determined by means of radiography. If it seems possible to replace by manipulation and extension, these means should be employed, preferably under general anæsthesia. Other radiograms should then be taken to determine the result attained. If satisfactory, well and good. If not, the surgeon should decide whether or not there is a reasonable prospect that better results will be obtained by a second trial. If he feels that he cannot obtain a satisfactory result by manipulation, the plates should be shown to the patient and his friends with a plain, candid statement as to the probable functional result and a recommendation that he be allowed to adopt the open method of treatment. If consent is obtained, the fracture should be plated at some convenient time. If not, the patient must be advised to accept the situation or go to some other surgeon who he thinks can do better for him. In this way all misunderstandings and strained relations between the surgeon and patient may be avoided.

2. In fracture of the neck of the femur, the Whitman position of abduction and flexion is recommended. If the fractured surfaces are kept apposed, the vessels will pass from the Haversian canals of the distal, to the Haversian canals of the proximal, fragment, and bony union will take place. Absorption of the proximal fragment and hyperextension will not develop. If the fragments cannot be apposed by manipulation and position, the distal fragment should be nailed to the proximal fragment through an incision. The head should be regarded as a bone graft. As emphasized by Murphy, there will seldom be any difficulty if the raw surfaces are contacted.

3. In comminuted fractures no fragments should be thrown away. It is not necessary that they should retain their periosteal covering or that they should have any attachment to the soft tissues. They may be removed, placed in warm, normal, saline solution and left there while the upper and lower fragments are brought into position. They can then be replaced in their original position, and treated as a bone graft. They will take perfectly well and contribute to an early and strong union.

4. There is not complete unanimity of opinion regarding the influence of the Lane plates on the rapidity of repair. Some surgeons think that they retard union. It may be difficult to determine this point definitely, but in the writer's experience there can be little doubt that they shorten the period of disability by permitting earlier massage of the muscles and mobilization of the joints.

SURGERY OF THE BONES, JOINTS, ETC.

Krabbel, M.: Plugging Bone Cavities with Free Transplantation of Fat (Zur Plombierung von Knochenhöhlen mit frei transplantiertem Fett). *Beitr. z. klin. Chir.*, 1913, lxxxv, 400.
By Zentralbl. f. d. ges. Chir. u. i. Grenzgeb.

Bone cavities were plugged with free transplanted fat in 10 cases. Four of these were cases of chronic osteomyelitis, five of tuberculosis and one of osteosarcoma. The technique employed was the same as that followed by Makkas. In five cases the fat healed in promptly, in three the plug was expelled, and in two cases there was a tuberculous relapse.

The proximity of an articular cavity or the necessity of opening such a cavity is not a contra-indication for the transplantation. If there be a tuberculous infection of the soft parts also, besides that of the bones, all of the diseased portions must be removed carefully. If a fistula forms, the plug must be removed immediately to avoid a relapse. The bone-formation advances but slowly and is only moderate after a year's time, as is demonstrated by radiograms.

CARL.

Weiss, R.: The Operative Treatment of Snapping Hip of Luxatio Tractus Iliotibialis Traumatica (Die operativen Behandlung der schnappenden Hüfte, der Luxatio tractus iliotibialis traumatica). *Monatsschr. f. Unfallheilk. u. Invalidenwesen*, 1913, xx, 162.
By Zentralbl. f. d. ges. Chir. u. i. Grenzgeb.

In the case described the painful snapping of the hip occurred after a fall against a railroad track. On operation, a completely isolated tendon-like part of the iliotibial band, the width of a finger, was found stretched over the trochanter, in no way connected with the tendinous or muscular part of the gluteus maximus and completely separated from the tensor fasciæ latæ. The band was cut, as it would have been of no use even if it was sutured to the posterior surface of the trochanter. The Trendelenburg sign was also negative. The patient was able to walk within twelve days after the operation.

GRASHEY.

Schewandin, M.: The End-Results of Lexer's Arthrodesis of the Ankle-Joint (Endresultate der Lexerschen Arthrodes am Sprunggelenk). *Arch. f. klin. Chir.*, 1913, ci, 1000.
By Zentralbl. f. d. ges. Chir. u. i. Grenzgeb.

Nine cases are reported in which arthrodesis of the ankle-joint was performed by Lexer's method, the use of a wedge of bone from the tibia with periosteum and marrow, or of a section of the fibula throughout its entire thickness. In every case the bone sections were obtained from the patient.

After the operation a plaster of Paris cast was used for from six to eight weeks. At the end of that time an ambulatory splint was worn for from two to four months. The cases have been observed from two to five years after operation. Five cases were examined personally by the author. Four patients sent a written report of their condition. In the first group there was one case of osseous arthrodesis, but in this patient, fourteen months after the operation, the malleolus was fractured to correct the position of the foot. The author believes that this procedure completed the ankylosis. In the second group one patient reports that he walks without pain, steps with the whole foot normally, and that there is no lateral movement.

By this method bony ankylosis in the articulation between the tibia and the astragalus does not occur often. It is more frequent in the articulation between the astragalus and os calcis. The arthrodesis lasts only until the interposed bone is absorbed, which requires different lengths of time in different cases. The cases all made uneventful recoveries.

WITTEK.

Depage: Resection of the Posterior Tarsus (Résection du tarse postérieur). *Ann. Soc. belge de chir.*, 1913, xxi, 97.

By Journal de Chirurgie.

Depage states that methods for resecting the tibiotarsal joint and the posterior tarsus are very numerous and a young surgeon may find it very difficult to make a choice between them when treating tuberculosis of the foot. This multiplicity of methods is due in part to the multiplicity of the sites of infection.

1. When the astragalus is tuberculous it may be removed by Vogt's method. While the removal of the astragalus is often practical, it is, however, often insufficient, for even if the adjoining synovial membranes are all removed, tuberculous foci may be left. Furthermore, this operation leaves a flat-foot which is not very serviceable.

2. Another method is resection of the tibiotarsal articulation by Hueter's method. This gave excellent results in the case reported by Depage. The tibial plateau, astragalus, calcaneum, and even the anterior tarsus may be removed, and all of the tuberculous foci may be cut away.

3. The mid-tarsal resection by two lateral incisions according to Koenig's method is not as good as the preceding.

4. Kocher's method of resecting the posterior tarsus and tibiotarsal articulation is of great value.

5. The tibiotarsal resection through an incision in the sole of the foot as recommended by Busch, Ssabanejew, and Bogdanik has no special advantages.

6. The method of posterior tibiotarsal resection of Vladimiroff-Mikulicz as modified by Krodnitz

and Kümmel gives a very serviceable foot, though the original operation caused shortening and talipes equinus.

It is difficult to say that any one of these methods is better than the other, and Depage advises making a careful radiographical study.

That method should be used which will best satisfy the requirements of the case and the following conditions: Preservation of the heel, and a clean section of the bone so that the surfaces made may be readily coapted.

J. DUMONT.

Zimmerman, B. F.: Tendon Transplantation in Talipes from Anterior Poliomyelitis. *Am. J. Surg.*, 1913, xxviii, 297. By Surg., Gynec. & Obst.

Manual and mechanical correction of talipes deformity is usually doubtful. Tendon transplantation with or without arthrodesis is the most appropriate method. Zimmerman believes that the paralysis of the muscle in talipes is real and is not due to lack of elasticity from overstretching. In the paralytic foot arthrodesis of the ankle joint may be performed regardless of the age of the patient.

The author quotes Campbell's rules for tendon transference, i. e. (1) the transferred muscle must be strong and healthy; no attempt should be made to utilize a muscle that is even slightly paretic; (2) the transferred tendon should be laid parallel for a considerable distance to the tendon for which it is to act in the future; (3) the transferred tendon must be tunneled through the subcutaneous fat in order that no adhesions may form.

Wetzler also is quoted: "(1) Paralyzed tendons do not stretch to an abnormal extent nor do they

tear as easily as is assumed. (2) Sutures anchored to paralyzed tendons withstand traction quite well, contrary to the views expressed by Lange and others.

Zimmerman then reports three cases of paralytic club foot with varus deformity. In these he first performed manual correction with tenotomies and fasciotomies, and a month later transplanted a portion of the tibialis anticus into the periosteum of the outer side of the foot. In two of the cases he performed arthrodesis of the calcaneo-cuboid joint. The deformity should first be corrected and the muscle restored to normal tone.

J. O. WALLACE.

ORTHOPEDICS IN GENERAL

Lucas, W. P., and Osgood, R. B.: Human Carriers in Poliomyelitis. *Am. J. Orth. Surg.*, 1913, xi, 135. By Surg., Gynec. & Obst.

Lucas and Osgood have produced typical poliomyelitis in rhesus monkeys by means of injections of a nasal secretion obtained from a boy who had had two typical attacks of poliomyelitis with resulting paralysis, and from which serum all other bacteria had been eliminated. The nasal secretion had persisted between the attacks. A sister of the boy had an attack of poliomyelitis after sleeping on a bed previously occupied by her brother. The nasal secretion which contained the virus was obtained over two years after the first attack and about four months after the second. This would seem to show that the virus of poliomyelitis may persist in the nasal secretion of human beings who have recovered from an acute attack of poliomyelitis.

GORDON HEYD.

SURGERY OF THE SPINAL COLUMN AND CORD

Bucholz, C. H.: Röntgen Ray Diagnosis of the Lumbar Spine and the Sacro-Iliac Articulations. *Tr. Am. Röntg. Ray Soc.*, Boston, 1913, Oct. By Surg., Gynec. & Obst.

Bucholz states that the study of the lumbar spine and the sacro-iliac articulations, especially that of the fifth lumbar vertebra, involves a great many problems of interest for the orthopedist, the neurologist, and the genito-urinary surgeon, as well as for the radiologist and the anatomist. Although the work of Goldthwaite, Boehm, Ludloff and many others has traced the path, much work is still to be done.

In the anatomical-radiological part of his paper special attention is called to the fifth lumbar vertebra and the particular difficulties of interpreting them by the X-ray because of the following factors: (1) The angle of inclination which cannot be averted in all cases; (2) the typical differences in the shape of the fifth and the upper lumbar vertebrae; and (3) the anatomical variations which are classified according to the amount and kind of variations of the transverse process of the last lumbar vertebra and

their connection with the sacrum, and the number of lumbar and sacral vertebrae. As examples of these different types several lantern slides were shown, some of which have been taken from Osgood's collection of orthopedic, medical, and surgical patients, which has been supplemented by the author, and others from Dodd's collection of röntgenograms of specimens from the Warren Museum at the Harvard Medical School.

In the pathology section of Bucholz's paper, brief attention was called to the following subjects: Fractures and dislocations of the lumbar vertebrae especially in the lumbo-sacral region, spondylolisthesis, lateral curvature, infectious arthritis, the various forms of hypertrophic arthritis, diseases of the spine, and affections of the sacro-iliac articulations.

The diagnosis of fractures of the fifth lumbar vertebra and of dislocations involves great difficulties and often cannot be made from the X-ray plate alone without a knowledge of the history and clinical symptoms.

Boehm's theory that lateral curvature is caused by anatomical variations is still under discussion, since

further experiences have shown that lateral curvature occurs in cases which do not show anatomical variations and that many cases with distinct anatomical variations have no signs of lateral curvature.

A differential diagnosis of spinal diseases and injuries is occasionally impossible. In the author's opinion, the X-ray diagnosis of the sacro-iliac displacement as described by Goldthwaite and Osgood is impossible, at least in the great majority of cases. The explanation of certain clinical pictures by such displacement rests mainly, if not solely, upon the history and the interpretation of the clinical symptoms.

The explanation that certain cases of backache may be due to variations in the shape of the last lumbar vertebra gives a bright outlook for a better understanding and more rational treatment of such cases, although, on the basis of our present knowledge, the occurrence of anatomical variations, in many such instances, may be considered as only a coincidence.

Lovett, R. W.: The Treatment of Scoliosis. *Tr. Internat. Cong. Med., Lond., 1913, Aug.*

By Surg., Gynec. & Obst.

A discussion of the modern treatment of scoliosis must begin with a definition of the term. The word "scoliosis" is used to include both the functional and the organic curvature of the spine, and a failure to recognize the division between the two will result in confusion in the matter of treatment and in the estimation of results.

Functional scoliosis, or false scoliosis, is a condition in which the spine is normal as regards gross changes, but the child stands with the spine curved to one side. The curve disappears when the body is in the recumbent position and is amenable to cure by gymnastic treatment.

Organic or structural scoliosis, on the other hand, is a change in the shape of the bones of the spine. The curve does not disappear in the recumbent position and it is accompanied by a twist of the vertebral column in a horizontal plane, the backward twist being on the side of the convexity of the lateral curve.

The functional form of scoliosis often changes to the organic form, but not to the severe type.

The most severe cases of organic scoliosis are due to congenital anomalies of the spine, empyema, infantile paralysis, or rickets. The position in which children sit at school may cause a mild scoliosis, but not the more severe forms.

The treatment of structural scoliosis is a difficult problem. Gymnastic treatment on the whole has been unsuccessful, for, as this form of scoliosis is a bone deformity, attempts to remedy by it muscle treatment are unreasonable. Forcible correction dates from the time of the elder Sayre, and in the opinion of the writer it constitutes the most rational treatment for the moderate and severe forms of structural scoliosis. The milder forms in many cases are amenable to gymnastic treatment.

Forcible correction consists of the application of a jacket with the patient in a corrected position. Various techniques are employed. The patient is suspended and lying on the face, side, or back. According to the method described by Abbott, the patient lies on the back with the spine flexed, and apparently in this position better correction is obtained than in the others. By whatever method applied the jacket should be cut away over the back of the collapsed side of the thorax, and pads should be inserted between the prominent parts of the thorax and the jacket, especially in the front.

The fear of permanent muscular atrophy from the use of such jackets appears to be unfounded. In cases in which an opportunity has been afforded to make observations over a long period of time the results have been found to be permanent. The patient must be retained in the corrected position for a good many months, at the end of which time a removable jacket and gymnastic exercises are of use. The whole treatment is not likely to take less than two years in cases of structural scoliosis of moderate or severe grade.

Adams, Z. B.: Treatment of Lateral Curvature of the Spine by the Forbes Method. *Am. J. Orth. Surg., 1913, xi, 97.*

By Surg., Gynec. & Obst.

Adams' article showed by diagram the course traveled by the vertebra from its normal position to the position which it occupies in scoliosis. He explained that the forces which move the thoracic vertebra are furnished by the ribs. The spring tension of the ribs causes the vertebrae to rotate.

Because of the shape and interlocking of the vertebrae, there is no rotation of the spine without lateral bending, and no lateral bending without rotation.

Another diagram was shown to illustrate the difference in the direction of the forces as applied by Abbott and by Forbes.

A simple method was described for applying jackets in the Forbes position of rotation.

Bade, P.: The Treatment of Spondylitic Paralyzes (*Zur Behandlung der spondylitischen Lähmungen*). *München. med. Wchnschr., 1913, lx, 1432.*

By Zentralbl. f. d. ges. Chir. u. i. Grenzgeb.

The author discusses the open and closed methods of treatment that have been employed heretofore. The new method consists in the application of an apparatus made up of sectional splints according to plaster of Paris models and consisting of parts for the feet, legs, and thighs, an abdominal corset, a shin rest, caps for the posterior part of the head, and an extension for the head. The joints in the apparatus are held in position by antagonistically acting rubber bands so that the position of the apparatus corresponds to the upright position of the body. The patient with the apparatus applied is placed in a walking chair and in a short time learns to use one group of muscles after another (8 days to 9 months).

Simultaneously with this treatment massage and gymnastics are begun twice daily. The individual parts of the apparatus are gradually taken off as the patient improves.

The advantage in this method lies in the fact that the patient is able to assume the upright posi-

tion immediately. As a result there are brought about more favorable circulatory conditions in the spine which favor the absorption of an abscess or oedema. Furthermore, on account of the passive stretching of the muscles the spasms are decreased.

SURGERY OF THE NERVOUS SYSTEM

Stoffel, A.: New Facts in Regard to the Nature of Sciatica and New Methods for the Operative Treatment of the Disease (Neues über das Wesen der Ischias und neue Wege für die operative Behandlung des Leidens). *München. med. Wchnschr.*, 1913, lx, 1365.

By Zentralbl. f. d. ges. Chir. u. i. Grenzgeb.

Stoffel states that it is incorrect to consider the sciatic nerve as a whole. It is necessary to differentiate within it a number of motor and sensory tracts similar to those in the trigeminal nerve. Diseases of these different individual tracts produce different clinical symptoms. As the various tracts always occupy the same position within the nerve it is possible to attack them individually by surgical measures. The Stoffel model of the nerve shows the individual tracts in cross section. The nerve is

exposed, the diseased tract is mobilized for a distance and severed. Neurexairesis of the proximal and distal part may then be performed. The absolute anæsthetic zone resulting is surprisingly small. The relative anæsthetic zone immediately following the operation is much larger but in time gradually decreases. Trophic disturbances or subjective disturbances never occur as a result of the anæsthesia.

In a severe case that resulted in scoliosis, this condition immediately improved after the operation (extirpation of the Nn. cutan. suræ med. et lat. and its tracts in June, 1912) without any special after-treatment. The patient since then has been absolutely without pain. The author intends to publish another article in regard to further details.

MISCELLANEOUS

CLINICAL ENTITIES — TUMORS, ULCERS, ABSCESES, ETC.

De Quervain, F.: The Position of Tumors in Nature (Über die Stellung der Geschwülste unter den Naturerscheinungen). Leipzig: Vogel, 1913.

By Zentralbl. f. d. ges. Chir. u. i. Grenzgeb.

In this lecture, delivered before a general scientific audience, the author gives his experiences of many years in regard to the tumor problem. In general, he recognizes three kinds of morbid stimuli: (1) Physical; (2) chemical; (3) parasitic. The third group cannot be sharply divided from the others, as its effect may be chemical as well as mechanical, but it differs from them in that its exciting cause is a living substance. The reactions following their action are also divided into three main groups: (1) Reparatory; (2) inflammatory; (3) tumor-forming.

The relation between cause and effect is discussed briefly with good examples. The parasitic effects, which are discussed more at length, often cannot be limited by time or place. The main part of the work deals with the neoplastic reactions. Their formation by various irritants, and analogous processes in the vegetable and lower animal kingdom, are ably discussed. Two tables give a survey of the various actions and reactions. Briefly discussed are tumors, especially congenital tumors, in which no irritant is demonstrable. In a theoretical investigation the

author regards it a mistake to separate tumors into benign and malignant, and believes that the tumor problem should be treated as a whole. For the clinician, of course, the separation is important. Every cell has the inherent ability to form tumors. The author ends his interesting study with a discussion of the subjects of predisposition and immunity, the purpose of tumor formation, healing and prophylaxis.

KLEINSCHMIDT.

Jansen, M.: On the Vulnerability of Fast Growing Cell Groups. *Tr. Internat. Cong. Med.*, Lond., 1913, Aug.

By Surg., Gynec. & Obst.

The author believes that the vulnerability of cells is in direct proportion to the rapidity of their growth. This principle is illustrated by the destructive action of the röntgen ray on fungus granulations, sperm cells, and other rapidly proliferating cells. This decreased resistance on the part of the more rapidly proliferating cells is seen also in cases where in the same tissue there is a difference in the rapidity of the growth of the cells. For example, the cells of the epiphyseal cartilage discs can be entirely stopped in their growth by the action of the röntgen ray without interfering with the remaining parts of the skeleton.

In rachitis the same principle is met. The disease in early infancy manifests itself in the form of cranial tabes, a consequence of the rapid growth of the

cranial bones to accommodate the rapidly enlarging brain. In later childhood, the disease affects mainly the skeleton of the extremities, which, during this period, shows the more rapid growth. The author explains the condition of achondroplasia in a similar way. He attributes the lack of cartilage development in this condition to the fact that the foetus is enclosed in an amniotic sac that is too small, and that "squeezes out its blood or most of its blood . . . The cartilage, the glutton of the tissues, suffers first and most from this famine."

The author believes that the increased vulnerability of rapidly growing cells may explain the localization of other pathological conditions, as, for example, the localization of osteomyelitis to epiphyseal ends of the diaphyses, and Czerny's exudative diathesis to the much exposed outer and inner coverings of the young body. The same principle may play a part in the development of cancer and explain the disappearance of certain rapidly growing tumors during the course of severe infection.

BARNEY BROOKS.

Weil, G. C.: Spontaneous and Artificial Development of Giant Cells in Vitro. *J. Pathol. & Bacteriol.*, 1913, xviii, No. 1.

By Surg., Gynec. & Obst.

Weil reports his studies on the method of development of foreign-body giant cells made by carefully observing their formation in cultures of splenic tissue in vitro, lycopodium spores having been added to the medium to act as foreign bodies. He found that the cellular activity about the foreign bodies follows a rather definite and uniform course:

1. Polymorphonuclear leucocytes with some lymphocytes promptly migrate to the region of the foreign body, surround it, and show amoeboid and phagocytic activity for several days, degenerating about the sixth day to a homogeneous mass with irregular nuclear masses, not a giant cell.

2. At the end of about thirty-six hours there appear in the culture large mononuclear cells which are readily distinguished from developing connective cells and which approach the foreign body by their amoeboid activity. These cells engulf the small foreign bodies, and on coming in contact with larger ones flatten out along their surfaces and become multinucleated foreign-body giant cells.

Weil was unable to observe the development of the giant cell directly, but by comparing the number of large amoeboid cells approaching a given foreign body during the development of the culture with the number of nuclei in the giant cells about the foreign body as seen in the final stained preparation, he concludes that the giant cell is the result of nuclear division in an individual cell.

H. B. LODER.

Harris, W. H.: The Association of Tuberculosis and Malignant Growths. *J. Med. Research*, 1913, xxviii, 471.

By Surg., Gynec. & Obst.

At present it is an undetermined problem just what relationship it is, if any, that tuberculosis and

malignant tumors occurring in the same area bear to each other. The author records his observations in the case of a white man, forty-five years of age, who presented clinical signs and symptoms indicative of laryngeal neoplasm. As far as could be determined by clinical methods, the lungs and other organs were normal. Repeated sputum examinations showed that no acid-fast bacilli were present. The Wassermann reaction was negative. On operation an irregular growth was found protruding just between the junction of the thyroid cartilages. Microscopical section showed this to be a distinct epidermoid carcinoma. A complete laryngectomy was then performed. Microscopical study of serial sections revealed the presence of a distinct epidermoid carcinoma of the spino-cellular type. In the stroma were seen epithelioid cell infiltrations with lymphoid and plasma cells scattered here and there. These infiltrations arose from underlying well-defined, miliary tubercles, which presented a central area of caseation with circumferentially arranged epithelioid cells, a few plasma and lymphoid cells, and an occasional giant cell. One year after the time of operation there were no evidences of recurrence of either the carcinoma or the tuberculosis. The patient had gained over 30 pounds in weight and was of ruddy color and apparently in the best of health.

The author thinks that perhaps in this combination in the larynx, the tuberculosis provoked the tumor formation by its destruction of the tissue relationship. He adds that the tumor probably found in the diseased area of tuberculosis the proper conditions for development; in other words, that the tuberculosis formed a primary pathological soil upon which the tumor thus provoked continued to flourish while the tuberculosis in part yielded.

GEORGE E. BEILBY.

Freund, E.: The Causes of Carcinoma (Die Ursachen des Carcinoms). *Tr. Internat. Cong. Med.*, Lond., 1913, Aug.

By Surg., Gynec. & Obst.

Freund asserts that in looking for the causes of carcinoma we must consider not the irritation that gives immediate rise to the growth, but the abnormality in the organism which allows it to produce that effect in the one individual of the many who are acted upon by the same irritant. Moreover, in the majority of the persons affected by carcinoma there is no irritation that might cause it. Therefore there must be a predisposition. Freund and Caminer have found that the blood of carcinoma patients acts very differently from the blood of normal individuals toward carcinoma cells. Normal blood destroys carcinoma cells; the blood of carcinomatous patients does not destroy them, and it prevents their destruction by normal blood.

The destructive power of normal blood on carcinoma cells is due to its content of a hitherto unknown fatty-acid combination that can be extracted with ether. This substance is lacking in carcinomatous blood. Moreover, carcinomatous

blood contains a pathological nucleoglobulin that is different chemically from normal nucleoglobulin in that it is richer in ether extract and carbohydrates, and, biologically, in that it combines the normal fatty-acids and makes them ineffective and protects the carcinoma cells from destruction by normal blood serum.

The important question as to whether these variations from normal are a cause or a result of carcinoma has still to be decided in part.

Stomach and other ulcers that are frequently the location for carcinoma differ from normal tissue in that they lack the cell-destroying fatty-acids.

Röntgenization, which often results in cancer, may neutralize this cell-destroying acid in the skin. The cell-destroying acid is lacking in places where carcinoma appears easily, even before the appearance of the carcinoma. The lack of the acid is therefore to be regarded as a local prerequisite for cancer.

It has been determined that in contradistinction to normal nucleoglobulin, the pathological nucleoglobulin has the property of attracting carbohydrates to it from the serum, and accordingly those substances that are found in special abundance in carcinomatous tissue. The nucleoglobulin seems to be the substance that provides the carcinoma with its special nutritive material. It has been determined how the pathological nucleoglobulin is formed from normal nucleoglobulin. The extracts of various organs from carcinomatous individuals can be added to a normal nucleoglobulin solution without changing its action upon carcinoma. But if an extract from the contents of the small intestine of a carcinomatous individual be added to a normal euglobulin solution, it takes on the chemical and biological properties of a carcinomatous nucleoglobulin and exercises a protective action on the carcinoma cells against normal serum. This active substance of the intestinal contents has been isolated. It is a hitherto unknown unsaturated fatty-acid combination that is found only in the small intestine of carcinomatous individuals. We must, therefore, assume that the katabolism of food in the intestine of carcinomatous subjects is pathological, giving rise to an abnormal substance which causes abnormal protein compounds and thereby a pathological state of nutrition of the cells.

Ihmori, M.: The Disappearance of a Round-Cellled Sarcoma in the Course of Erysipelas (Verschwinden eines Rundzellensarkomes im Verlauf eines Erysipels). *Nippon-Geka-Gakkai-Zasshi*, 1913, xiv, 65. By Zentralbl. f. d. ges. Chir. u. i. Grenzgeb.

A woman, fifty-six years of age, was operated upon for an ovarian cyst of the right side. A tumor the size of a hen's egg was found on the left side of the umbilicus. At the end of two months it was as large as a child's fist. It was then extirpated. After a short time a tumor as large as a fist, with a nodular surface, reappeared, accompanied by severe pain. A hæmorrhagic erysipelas bullosum set in

and within a week both the tumor and a metastasis in the inguinal glands disappeared. Although the patient recovered from the erysipelas, she died from exhaustion.

OYAMA.

Citelli, S.: A Very Useful Method in Treating Hysterical Aphonia (Sur une methode tres utile pour guérir l'aphonie hysterique). *Tr. Internal. Cong. Med.*, Lond., 1913, Aug. By Surg., Gynec. & Obst.

Citelli's method consists in making very strong, painful, and sudden pressure when the patient is not expecting it, on the large cornua of the hyoid or the thyroid cartilage. This should be done with the first two fingers of the right hand after having caught the nape of the patient's neck with the left. The physician then demands in a loud tone of voice that he speak and the patient, frightened out of obedience to his morbid state of consciousness, finally answers in his normal voice.

Smith, G. M.: Morphological Changes in Tissue with Changes in Environment; Replacement of Surface Epithelium of Grafted Tissue by Adjacent Epithelium. *J. Med. Research*, 1913, xxviii, 423. By Surg., Gynec. & Obst.

The author's purpose in this paper is to record a number of experiments showing invasion of the surface epithelium of grafted tissue from hollow abdominal organs by neighboring cells, and to define some of the factors which underly the process.

Operative technique: Whenever possible a direct implantation of one organ into another was made by the suture method. In cases in which, for topographical reasons, a direct implantation was found to be impossible, the following method of transplantation in two stages was adopted for the transfer of tissues. By a preliminary operation a loop of intestine supplied with a freely movable mesentery was sewed to the outer wall of the organ from which the tissue was to be removed for transplantation. At the end of a week or ten days the second operation of tissue transfer was performed. The tissue of the organ to be transplanted was resected in such a manner that its center lay at the point of its attachment to the intestinal loop, from which it then received its new blood supply. The tissue was next trimmed down to the desired size, usually from three to four centimeters in diameter, and was ready for implantation. A second abdominal incision was made over the organ about to receive the graft, and the tissue to be transplanted, attached to the loop of intestine and properly protected by gauze, was drawn through the peritoneal cavity and brought into a position suitable for the implantation. In this way tissues from the gall-bladder, urinary bladder, or uterus could be readily transferred to any part of the peritoneal cavity for anastomosis with other hollow organs.

Smith's article is based on the results of fifty operative experiments on dogs, and the protocols of illustrative cases are given. From this experimental study the author draws the following conclusions:

Following autoplasmic transplantation of part of one hollow abdominal organ into the wall of another the epithelial surface of the implanted organ may undergo a change in structure. This change occurs when the epithelium of one organ differs in type from that of the other and is the result of the replacement of the epithelium of the graft by another that is derived from the organ that has received the implanted tissue.

Replacement of the epithelium of grafted tissue depends upon the change in environmental conditions. Changed physical and chemical conditions dependent upon the peculiar function of the organ which receives the graft affect unfavorably the life and growth of transplanted epithelium, while the same conditions favor the activity of the regional invading cells.

Whereas a replacement of the epithelium of grafted tissue may follow implantation into another hollow organ, the epithelium of the same organs gives no evidence of replacement when their tissues grow in contact under equal conditions within the peritoneal cavity.

GEORGE E. BEILBY.

Küttner, H.: The Importance of Free Transplantation in Modern Surgery (Die freie Transplantation und ihre Bedeutung für die moderne Chirurgie). *Naturwissenschaft.*, 1913, i, 513.

By Zentralbl. f. d. ges. Chir. u. i. Grenzgeb.

This article is a short review of the theory and practice of free transplantation in modern surgery. In contrast to the possibilities in the lower animal orders, and in the embryonic state of the lower vertebrates, transplantation in man is limited within very narrow boundaries. Autotransplantation is the only form in which there is any certainty that the transplanted tissue will remain alive. Material for transplantation must be obtained from other human beings if the patient himself cannot furnish it. Transplantation from animals to man is now rejected. Küttner believes that in this we go a little too far. He reports a successful transplantation performed a year and a half ago of a fibula from a macacus cynomolgus to a man. According to the röntgen picture, the monkey's bone remained unchanged and there were no signs that absorption had taken place.

Bruck gives the biological relationship of man and the higher apes as follows: (1) Man; (2) orang-utan; (3) gibbon; (4) macacus rhesus and nemestrinus, and (5) macacus cynomolgus. He thinks that biologically man is about as far removed from the orang-utan as the latter is removed from the macacus rhesus. According to Friedenthal, man and the macacus are considerably nearer than rabbits and guinea pigs.

Aside from the particular form of hetero-transplantation mentioned, the only possible transplantation in man is auto- or homo-transplantation. The transplantation of entire organs by suturing the blood vessels is successful only on autotransplantation and therefore has no practical value. The attempt to perform homoplastic transplantation in a

position of parabiosis has not given satisfactory results. Transplantation of glandular organs such as the thyroid, without regard to the blood vessels, has shown that even in homoplastic transplantation from closely related individuals absorption eventually takes place in spite of beginning reparative processes and that only on autotransplantation can any increase in size of the transplanted organ be observed. Küttner recommends therefore, instead of transplantation, the administration of macerated normal human thyroid substance. According to Landois' experiments, the suprarenal glands also persist only on autotransplantation.

The author considers briefly the possibilities of transplanting suprarenals, testes, ovaries, muscle and nerve tissue, entire extremities, epidermis, skin, mucous membrane, fat, fascia, tendons, serous membrane, blood vessels, bone, periosteum, cartilage, and joints. He goes into more detail in considering the transplantation of joints from the cadaver. Before using material from the cadaver, which should be as fresh as possible, a bacteriological examination should be made. Two cases have shown that material can be used successfully twenty-seven and thirty-five hours after death. Therefore, there is sufficient time for a bacteriological examination if it be hurried. A description is given of two successful cases of transplantation of bone from the cadaver for chondrosarcoma, and further use of such transplantation is recommended.

HELLER.

Ssisemski, W. W.: The Clinical Character and the Treatment of Railway Injuries (Der klinische Charakter und die Therapie der Eisenbahnverletzungen). *Russk. Vrach.*, St. Petersburg. 1913, xii, 24.

By Zentralbl. f. d. ges. Chir. u. i. Grenzgeb.

The author reports five hundred and two injuries to railroad workers observed in the three hospitals of the Nikolai railroad from 1904 to 1910. Of these, ninety-two cases were contusions with no mortality; one hundred and ten, wounds of soft tissues with a four per cent mortality; seventy, simple fractures with a mortality of five per cent; one hundred and ninety-seven, compound fractures with a mortality of thirty-three per cent, and thirty-three, miscellaneous injuries such as burns, luxations, concussions of the brain, etc., with a mortality of thirty per cent. Ssisemski characterizes railway injuries as follows: 1. They are generally multiple. 2. All wounds are infected. 3. They are complicated by severe contusions. 4. There is severe hæmorrhage. 5. The wound surfaces are large. Injuries of this kind have a characteristic course which the author divides into three periods: 1. A period of shock lasting from a few hours to twenty-four hours. 2. A period of recovery from the wound lasting from three to five days. 3. A period of recovery of the body from infection and intoxication, the duration of which depends largely on the size of the area injured. The treatment should be confined in the first period to combating the shock by giving large doses of

morphine and saline infusions of 2000 cc. and more. Operative procedures should be undertaken during the second period and should be as radical as possible. The following principles should be observed: 1. Wounds of the soft parts should be given open treatment. 2. In complicated fractures of the long bones, especially if the large joints are involved, a high operation is to be preferred to conservative treatment. 3. All depressed fractures of the skull should be trephined. In the third period general tonic treatment is most important. Warm baths and alcoholic compresses are recommended.

RIESENKAMPFF.

SERA, VACCINES, AND FERMENTS

Sahli: Theses on Tuberculin Treatment. *Lancet*, Lond., 1913, clxxxv, 379. By Surg., Gynec. & Obst.

All of the various tuberculins are essentially identical. The active principle is the protein of the tubercle bacilli.

To avoid disastrous mistakes in therapeutic dosage it is advisable to provide the practitioner with tuberculin in suitably graduated dilutions.

The use of tuberculin for diagnostic purposes ought to be condemned. It is unreliable, both positively and negatively. Diagnostic injections are dangerous.

Tuberculin treatment is free from danger only if more obvious clinical reactions are avoided.

In advanced cases tuberculin treatment may sometimes produce a certain symptomatic effect, but this effect does not compare with the utility of tuberculin in incipient cases.

The general practitioner, and especially the family physician, should render himself proficient in tuberculin treatment.

The theory of the therapeutical action of tuberculin may now be regarded as well established. The significant factor is the increased production of that which Sahli has called "inflammatory antibodies" and the specific tuberculin amboceptor.

Tuberculin acts favorably only when the human organism is not already sufficiently under the influence of absorbed tuberculin.

It is not necessary to increase the doses of tuberculin to the furthest limit of tolerance. Many cases improve more with a much smaller dose.

The large doses of tuberculin recommended recently for the purpose of reducing temperature have no curative value.

In tuberculin treatment we look for only stimulation and activation of the counteractions of the body at each injection.

All localized tuberculosis is suitable for tuberculin treatment provided that the patient's system is not already overloaded with tuberculin and he is, therefore, too seriously ill. As a rule, acute cases cannot be treated by tuberculin.

Tuberculin treatment by means of multiple cuti-reactions has been proved harmless and useful especially for incipient cases.

Treatment with well-diluted tuberculin is a real and great advance in therapeutical progress.

DONALD C. BALFOUR.

Von Behring, E.: A New Diphtheria Antitoxin (Über ein neues Diphtherieschutzmittel). *Deutsche med. Wchnschr.*, 1913, xxxix, 873.

By Zentralbl. f. d. ges. Chir. u. i. Grenzgeb.

This article is a short review of a paper read by von Behring before the Congress of Internal Medicine in Wiesbaden on April 18, 1913. The remedy, designated by him as M_1M_1 or MM_1 consists of a mixture of diphtheria toxin and antitoxin, and represents in its composition the result of exacting experimental studies made by him on all available animals. Purposes of the vaccination are: (1). To produce a long-continued immunity. (2). To acquire an anthropogenous—i.e., native human antitoxin—from highly immunized subjects for passive immunization in place of the usual foreign antitoxin secured from the horse. (3). To effect the more rapid removal of diphtheria bacilli in diphtheria carriers.

The injections are made subcutaneously and intramuscularly. An exact program is given for the test. After injection of the material, many antibodies are formed rapidly and there is a rise of fever. Most of these antibodies disappear from the blood just as rapidly as in the usual passive immunization with the serum. When the new remedy is used, however, a sufficient quantity of the newly formed immune bodies remains in the blood for longer periods as a protection against the disease. In the horses that he immunized with diphtheria toxin von Behring was able to demonstrate the presence of antibodies in the blood five years after the last vaccination. In one case a child was immunized with an anthropogenous serum gained from another child.

It was found that this anthropogenous antitoxin as regards its disappearance from the blood does not differ materially from the autogenous antitoxin acquired in the process of active immunization. The absolute harmlessness of the remedy has been proved by the trials made hitherto (eighty cases). Similar to Jenner's vaccine-therapy, one to two injections of von Behring's new remedy produce long-continued protection against infection without injuring the health of those vaccinated. Besides being of eminently practical significance, von Behring's new discovery modifies very materially our views on the effect of toxin on antitoxin. According to his results, a definitive and irreversible neutralization of the toxin in vitro such as has hitherto been supposed to take place is impossible.

ECKERT.

Cruickshank, J., and Mackie, T. J.: Alterations Produced in Complement-Containing Serum by Introduction of Lecithin. *J. Pathol. & Bacteriol.*, 1913, xviii, No. 1. By Surg., Gynec. & Obst.

Cruickshank and Mackie report a highly technical research on the nature of complement action. Lecithin prepared from egg-yolk was rapidly added to diluted serum and the globulin and albumin

fractions then separated by precipitation of the former with carbon dioxide gas. The lecithin fractions thus obtained, as well as the whole serum, were tested as to their hæmolytic power in various combinations. The authors summarize their results as follows:

1. The introduction of lecithin into complement-containing serum of the guinea-pig does not materially alter the complement dose; in the case of rabbits' serum the complementary activity is frequently increased.

2. The albumin fraction from a serum treated with lecithin is as actively hæmolytic for sensitized corpuscles as the original complement, while the globulin fraction retains the property of acting effectively with the ordinary albumin fraction.

3. The addition of lecithin to ordinary albumin fraction after separation does not enhance the complement activity of the fraction.

4. The lecithin must be mixed rapidly with the serum, or with the water used for dilution, in order to produce the effect described; slow admixture does not yield an active lecithin-albumin fraction.

5. The albumin fraction of a serum treated with lecithin is "absorbed" by complement-absorbing agents; it can also replace the complement in the Wassermann reaction.

6. The activity of the lecithin-albumin fraction is dependent upon the presence of "complement" in the original serum.

7. Lecithins differ markedly with regard to their power to produce the alterations described.

The authors suggest that lecithin acts by rendering active a component of a complement which is normally present in an inactive or latent state, but they feel that this theory is not complete enough to account for the increase of complement activity which results with certain rabbit sera merely on the addition of lecithin.

G. G. SMITH.

Auer and Van Slyke: A Contribution to the Relation Between Proteid Cleavage Products and Anaphylaxis. *J. Exp. Med.*, 1913, xviii, 210.

By Surg., Gynec. & Obst.

On examination of the anaphylactic lung by means of Van Slyke's amino nitrogen method, the authors found no evidence of an increased amount of proteid cleavage products. They conclude that the investigation gives no support to the hypothesis that the true anaphylactic lung of the guinea pig is caused by the products of protein cleavage.

JAMES F. CHURCHILL.

BLOOD

O'Brien, R. A.: Rate of Reproduction of Various Constituents of Blood of Immunized Horse After a Large Bleeding. *J. Pathol. & Bacteriol.*, 1913, xviii, 89.

By Surg., Gynec. & Obst.

Using the blood of two immunized horses from each of which had been taken ten litres, O'Brien followed the reproduction of various constituents for

thirty-four and forty-seven days respectively. He gives charts and tables showing his results, which he summarizes as follows:

1. The number of white cells varies widely and irregularly.

2. The hæmolytic titre remains practically constant, the variations being at most only ten per cent from the initial figure.

3. The total amount of salts present does not decrease, but may be increased ten per cent.

4. The content of all other blood constituents falls. The hæmoglobin and numbers of red cells fall together to 50 or 60 per cent of the initial figure.

5. The curves of total proteins and diphtheria antitoxins show a close relation.

G. G. SMITH.

Heyter, H.: Contributions to Hæmophilia (Kasuistische Beiträge zur Hämophilie). *Mitt. a. d. Hamb. Staatskrankenanst.*, 1913, xiv, 9.

By Zentrabl. f. d. ges. Chir. u. i. Grenzgeb.

Three cases of hæmophilia observed for a period of ten years are reported. The first case was that of an hereditary bleeder, in whom puberty had no effect upon the disease, except to change the early joint hæmorrhage to renal hæmorrhage. The latter stopped after rest in bed, a diet poor in meat, and the administration of gelatine, calcium salts, serum, and calcine. In the second case there was a congenital anomaly but no hereditary element. Hæmorrhage into the joints predominated, and was treated at first with iodoform-glycerin injections, as an incorrect diagnosis of tuberculosis had been made. Ovarian tablets had no curative effects, but calcium chlorate (a 2 per cent solution, three tablespoonfuls daily) had a good effect. A severe hæmorrhage in the floor of the mouth necessitated a tracheotomy. The third case was a typical hereditary bleeder (over four generations). Effusions into the joints were prominent. Ovarian tablets were effective. Of theoretical interest, and perhaps of practical significance, is the recommendation of ovarian tablets and calcine. Grant made his deductions from the fact that women are practically exempt from hæmophilia. Suspecting an internal secretory, antagonistic hormone, he wished to secure this in the organ extract, and administer it to the male body. Calcine is a combination of calcium and gelatine; the hæmostyptic action of the two components is well known. Besides calcine, a meat-free diet, milk, uncooked fruit, and abstinence from alcohol are recommended for bleeders.

KREUTER.

BLOOD AND LYMPH VESSELS

Hesse, E.: A Palpatory Symptom of Valvular Insufficiency in Beginning and Invisible Varices (Über ein palpatorisches Symptom der Klappeninsuffizienz bei beginnenden und nicht sichtbaren Varicen). *Beitr. z. klin. Chir.*, 1913, lxxxv, 591.

By Zentrabl. f. d. ges. Chir. u. i. Grenzgeb.

In answering the question as to whether valvular insufficiency of the vena saphena magna is present

or not when Trendelenburg's symptom is not visible to the eye, Hesse argues that the symptom described by Hackenbruch as "fluctuation shock" (a wavelike motion in a centripetal direction) is not to be regarded as physiologically normal, as it is also observed when the valves of the saphena are sufficient. On the other hand, the symptom given by Schwarz, a wave-like movement in a centrifugal direction, is proof of a valvular insufficiency: palpation of the proximal segment of the saphena produces fluctuation in the lower parts of the saphena. Hackenbruch's symptom of stenotic murmur ("Durchspritzschwirrens") has also some significance. Hesse describes a new symptom, palpation of the regurgitative blood stream, which is of value in patients with so-called invisible or beginning varices—nutritional disturbances in the leg, ulcers, and difficulties in walking that cannot be accounted for.

The saphena is looked for on the inner side of the knee and its course is marked on the skin with iodine. With the patient in the horizontal position the leg is elevated and the blood massaged out of the saphena. Its trunk is then compressed in the fossa ovalis and the patient brought into an upright position. Two fingers of the free hand are placed on the iodine line, which corresponds to the invisible saphena. In cases of valvular incompetency there is a regurgitation of blood, the slightest variations of which are detected by the palpating finger as "rushing eddies" ("surrende Wirbelströme"). Frequently they may be heard with the stethoscope. In these cases sapheno-femoral anastomosis gives splendid permanent results. DRAUDT.

Guggenheim, H.: On Lymphogranulomatosis and Its Relation to Other Systematized Lesions of the Hæmoporetic System (De la lymphogranulomatose et de ces rapports avec les autres lésions systématisées de l'appareil hématoporetique). *Thèse de doct., Par., 1913.* By Journal de Chirurgie.

Guggenheim reports two cases of lymphogranulomatosis in which he made a bacteriological and an histological examination of the glands and blood. Bacteriologically his results were negative, as were all tests for tuberculosis and syphilis. There was a slight leucocytosis with a relative increase in polymorphonuclear cells.

The glands of the neck, axilla, and groin were examined microscopically. It was noted that the normal architecture of the gland was lost and had been replaced by a fibrous meshwork in which were found lymphocytes, plasma-cells, endothelial cells, and eosinophiles of lymphoid origin.

The first case was that of a woman, thirty years of age, who died from tracheo-bronchial adenopathy despite three operations and treatment with arsenic. The second was that of a woman of forty to whom some benefit had come from intensive treatment.

Guggenheim next reviews the cases of non-specific, non-leukæmic, non-tuberculous adenopathy reported during the last ten years and finds that the following terms are used somewhat indiscriminately by various

authors: Hodgkins' disease, Trousseau's adenitis, aleukæmic lymphoma, pseudoleukæmia, lymphosarcoma, lymphogranulomatosis, etc.

He believes that the condition which he describes as lymphogranulomatosis deserves a distinct place in a classification which includes also lymphosarcoma, a metastasis-forming, tissue-invading and destroying tumor, and the aleukæmic lymphocytoma of Vaquez, or pseudolykæmia of Pinkus, a condition in which there is a hyperplasia of the lymphoid cells, and the adenopathies of tuberculosis, syphilis, leprosy, etc.

JEAN CLUNET.

SURGICAL THERAPEUTICS

Beck, E. G.: The Present Status of Bismuth-Paste Treatment of Suppurative Sinuses and Empyema. *Tr. Internat. Cong. Med., Lond., 1913, Aug.* By Surg., Gynec. & Obst.

The author gives a resumé of his experience in treating 1100 cases with the bismuth-paste method in the past eight years, and summarizes the work of other surgeons in America and abroad. These reports represent a class of cases in which the use of bismuth paste was preceded by other treatment.

The author's own material consisted of surgical cases in which all other means of treatment, surgical, medical, etc., had been tried previously. Only six per cent were finally given up as hopeless. Many instructive cases are cited in which a well-planned operation, following a correct diagnosis by means of tracing the sinuses to the focus of the disease, was effective, or, when operation was not feasible, the sinuses were closed by merely the injection of the bismuth paste. The bismuth-paste treatment fails only when the technique is not carried out properly, when the instruments used cannot meet the essential requirement of filling all of the sinuses at once, and when foreign bodies, such as rubber tubing, the end of a probe, or sequestra, that should have been removed before the injection, are still present.

In the series of 1100 cases treated by the author and his brothers there were no fatalities from bismuth poisoning, due to the fact that the bismuth paste was applied properly. All fatalities from poisoning reported by others occurred during the first five years that the method was in use. No report of fatalities has been made in the last year although the bismuth-paste treatment has been used even more extensively than before.

Beck employs a ten per cent paste in cases of cold abscesses to prevent the formation of sinuses and obtains good results.

ELECTROLOGY

Cannon, W. B.: The Early Use of the Röntgen Ray in the Study of the Alimentary Canal. *Tr. Am. Röntg. Ray Soc., Boston, 1913, Oct.* By Surg., Gynec. & Obst.

After reviewing the earliest experiments to make manifest the contours of hollow organs, such as

arteries, by injecting metallic salts, the author gave an account of the first observations of the movements of the cesophagus and stomach as seen when food was mixed with subnitrate of bismuth and examined by means of the röntgen rays. Cannon maintains that the method now so widely used in examining the alimentary tract was developed gradually, and that there is little warrant for ascribing its invention to any one person.

Holland, C. T.: *The Statistics of the X-Ray Examination for Stone in the Urinary Tract.* *Tr. Internat. Cong. Med.*, Lond., 1913, Aug.
By Surg., Gynec. & Obst.

The author analyzes in detail the X-ray findings of 1707 cases, and discusses the various conditions shown by X-rays and the percentage of cases in which each was found. He considers also the question of differential diagnosis. Pelvic shadows other than those of stone occurred in the proportion of 1 in every 3.43 males and 1 in every 4 females; calcareous glands were noted in 1 in every 8 males and in 1 in every 6 females.

With regard to kidney and ureter stones, stress is laid on the necessity of a complete examination in all cases. A stone or stones were found in 402 out of 1603 patients examined, or once in every 4 cases. The stone was found on the right side 258 times, and on the left 200 times, the extra number being due to the fact that in many cases more than one stone occurred in the ureter or kidney of the same patient, sometimes on opposite sides.

The X-ray findings of stone were very few indeed, and it was sometimes difficult to determine whether the shadow found was really that of a stone or that of some other condition. Frequently small pure uric acid stones found to be present at the time of examination and passed later on were not noted in the X-ray examination.

Pure uric acid stones in a kidney or ureter must be extremely rare as none were found in any of the cases in which the kidney was operated upon after a negative X-ray examination. The number of operations following negative X-ray examinations was 85 and in almost all of these cases some other cause was found for the symptom.

Attention was called to the fact that a negative X-ray diagnosis does not necessarily mean that there are no stones in the bladder, for in 4 out of 104 cases in which bladder stones were found there was no X-ray shadow. In each of these four cases the stone was found on analysis to consist of pure uric acid and moisture.

Lazarus-Barlow, W. S.: *The Effect of Radio-Active Substances and Radiations Upon Normal and Pathological Tissues.* *Tr. Internat. Cong. Med.*, Lond., 1913, Aug.

By Surg., Gynec. & Obst.

There is much evidence that a destructive or injurious effect is exerted by radium and that this is bound up chiefly with the alpha rays. From the

laboratory point of view, evidence concerning the beta and gamma rays is less convincing, and in the case of the latter, the opinion is gaining ground that the clinical effects that have undoubtedly been noted depend upon the secondary beta rays to which gamma rays give rise on meeting with an obstructing substance. Doses of radiation less than those producing definite destructive effects produce an inhibition; thus, mouse cancer cells irradiated to a degree short of killing them grow more slowly on transplantation. It is evident that even smaller doses stimulate the growth of cells. This fact is of importance since the author has found small quantities of radium element in cancerous tissues and in gall-stones associated with cancer of the gall-bladder, whereas normal tissues and gall-stones not associated with cancer of the gall-bladder showed either no radium or traces on the verge of experimental error. Mottram had shown in his laboratory that cells in mitosis are about seven times as vulnerable to radium as cells in the resting stage.

Saubermann: *Progress of Radium-Therapy.* *Arch. Röntg. Ray*, 1913, xviii, 98.

By Surg., Gynec. & Obst.

In the light of present-day knowledge the indications for radium therapy are: (1) rheumatism of the joints and muscles, acute and chronic; (2) arthritis, subacute, chronic, deformative and gonorrhœal; (3) neuralgia, intercostal neuralgia, etc.; (4) sciatica, including inflammation of the nerve ends; (5) gout, uric acid diathesis; (6) tabes dorsalis, diminution of lightning pains; (7) catarrh of the antrum and frontal sinus; (8) arteriosclerosis; (9) blood diseases; (10) constipation; (11) diabetes and glycosuria; and (12) nephritis.

The beneficial clinical results in this varied list of diseases are due to physiological actions the existence of which can be proven in living organisms. Some of the experimental results demonstrate the following facts: (1) radium emanation promotes the growth and multiplication of healthy cells and the decay of morbid cells; (2) in man, the emanation produces diuresis; (3) radio-active water stimulates the digestive tract and produces catharsis; (4) the uric acid and urea content of the urine is markedly increased; (5) vaso-dilation is produced; (6) the viscosity of the blood is diminished; (7) the blood pressure is lowered, probably because of (5) and (6); (8) metabolism is increased, especially that of hydrocarbons; (9) digestion both in the stomach and in the intestines is rendered more active; (10) there is a nerve-soothing effect which may aid to check insomnia; (11) sexual activity is increased; (12) the effect on the blood is leucocytosis followed by leucopenia with increase in the number of the red corpuscles.

The cause for these physiological effects is not so easy to determine. There is reason to believe that they are due to an increase in the activity of body ferments. At least it is easy to prove experimentally that ferment action is greatly increased by the in-

fluence of radium, and as a working basis it is assumed that such is the action within the human body.

Radium increases the activity of ferments as would a catalytic agent, either starting chemical changes or hastening their action if already in progress. The result is increased oxidation of the products of metabolism. This oxidation in diabetics takes the place of oxidation by the normal ferments the function of which is said to be disturbed in diabetes, although it is true that the symptoms of neuritis have been aided by radium treatment more often than the glycosuria.

The results in nephritis, arterial changes, etc., also are explained as being the result of an increase in the ferment action caused by the radium. One of the facts upon which this conclusion is based is that in artificial nephritis, etc., the ferments are destroyed by the poisons that produce the disease.

HOLLIS E. POTTER.

Lange: Röntgenotherapy in Measured Massive Doses. *J. Am. M. Ass.*, 1913, lxi, 556.

By Surg., Gynec. & Obst.

Lange discusses the principles underlying the X-ray treatment of malignant growths and points out the importance of a measured dose by which the X-ray treatment is placed upon a rational biological basis. He states that the treatment of uterine myomas, climacteric hæmorrhage, and uterine cancer by the X-ray became successful only when the massive dose technique was adopted and use was made of an aluminum filter of 3 mm., and a compression band to exsanguinate and desensitize the skin.

By the massive dose technique it is possible to give four times the erythema dose at one exposure and in one series extending over several days, and to subject the same area of skin to from six to ten times the erythema dose without apparent injury. Also, by varying the area of the skin exposed, tremendous quantities of the Röntgen rays may be delivered to the deep tissues. The possibility of administering a measured massive dose is a *sine qua non* of successful röntgenotherapy.

HENRY SCHMITZ.

Abbe, R.: Radium in Malignant Disease. *Tr. Internat. Cong. Med.*, Lond., 1913, Aug.

By Surg., Gynec. & Obst.

The author stated that while universal testimony agrees that the vast majority of superficial, and some internal, cancers can be cured by radium, there are still some failures and they need to be explained. This explanation he has found in an experimental study of the growth of plants that had been exposed to radium at different distances and for different periods. He showed beautiful photographs of plant growth to prove that the close application of radium destroys life, but when the rays are within the range of half an inch to an inch and a half they excite and stimulate growth. Beyond that radius the so-called

gamma rays prevent growth. It is these that are the only ones that are of value in reducing malignant tumors.

It has been proved by the French that heavy lead plate will shut out the harmful rays and permit the useful gamma rays to go through slowly and to destroy malignant tumors.

However, by the new plan of "distance filtration," without lead plate, the same, or better, results are obtained in a quarter of the time, or less. The radium is held at a distance of one and a half inches and in this manner most of the undesirable rays are excluded.

The author showed also many illustrations of the wonders worked by radium—numerous cases of tumors on the vocal cords, which destroyed the singing and speaking voice and obstructed breathing, and which were cured by one strong application for thirty minutes; the tumors disappeared in eight weeks.

A remarkable illustration was that of a gentleman on whose very bald head had grown many malignant tumors for eight months. One application of radium by the new method of distance filtration caused their complete disappearance in twelve days.

Of interest also were illustrations of malignant destructive bone tumors cured with restoration of the bone by burying radium in them. The earliest case remains cured nine years after the treatment.

Abbe spoke enthusiastically of the great work of the British Radium Institute and of recent German work, the results of which have all been corroborated by his own experience.

Pusey, W. A.: What Can be Done in Cancer with Röntgen Rays? *J. Am. M. Ass.*, 1913, lxi, 552.

By Surg., Gynec. & Obst.

The author regrets the partial disrepute into which the X-ray method of treating cancer has fallen since the advent of a more general, and consequently haphazard, use of the rays. The present scepticism is no doubt largely a result of observations made upon cases treated with mediocre skill. In the hands of trained men the results obtained to-day from this method demand an even greater recognition than those obtained in the early days of great promise.

Epitheliomas, irrespective of type, may be symptomatically cured by röntgen rays if the subcutaneous tissues are not deeply involved and there are no metastases. Occasionally growths with deep extension, even those involving bone and regional lymph nodes, respond in a remarkable manner.

As a rule, those cases are to be chosen for röntgen-ray treatment in which there is no involvement of regional lymph glands. Such cases with proper treatment give results which compare favorably with those of any other method. When a good scar can be obtained, they are usually permanent.

Following surgical removal, the X-rays play an important rôle in preventing the recurrence of localized cancers near the surface. This is particu-

larly true of breast cancers in which dissemination has not taken place. The röntgen treatment is without avail in cancers of the deeper viscera or in cases where metastasis has occurred.

HOLLIS E. POTTER.

Holding, A. F.: The Röntgen Technique of Deep Therapy. *Tr. Am. Röntg. Ray Soc.*, Boston, 1913, Oct.
By Surg., Gynec. & Obst.

Holding stated that: (1) A review of the medical literature up to 1909 shows that there had been reported up to that time 3134 cases of malignant conditions treated by röntgen methods. The results varied more according to the röntgenologists' technique than according to the morphology of the tumor. (2) A review of the medical literature shows that in 667 cases of myoma treated by röntgen methods in which the end-results were known, 376 cases were cured and 208 were improved. Of 271 cases in which the end-results were known, 206 were reported cured, and 206 were improved. (3) Ashoff, Kronig, Gauss, Bumm, and Voight published conclusive reports as to the effects of deep röntgen therapy on carcinomas of the face, breast, rectum, uterus cervix, and vulva. Bumm and Voight used mesothorium in conjunction with the deep röntgen therapy.

A sufficient number of good results have been reported to compel the consideration of deep röntgen therapy by the leaders of the medical profession.

Measured massive doses with filters, and the use of the most penetrating rays give the most successful results. Unmeasured, fractional, "three-times-a-week" röntgen treatments are condemned.

A resumé of the essentials of the Gauss technique for the treatment of myomas, carcinomas, etc., was given as follows: (1) the use of hard tubes—Walter 6-8, Wehnelt 9-10; (2) the use of a filter of aluminum 3 mm. thick; (3) the use of a circuit breaker in the primary current so that 100 to 120 impulses per minute may be delivered to the tube; (4) the division of the skin over the site of the disease into small areas 2 cm. square and the treating of each area separately and only once in a series; (5) the administration to each area of skin of 15 X or one and one half times the erythema dose; (6) a "cross firing" of the rays so that the rays directed at different angles through different areas of skin converge at the site of the disease; (7) the directing of the rays toward the site of the disease from every angle from the front, back, sides, above and below; and (8) the administration of the treatment in series. A series consists of 300 to 550 X administered on one or two days. This is followed by an interval of about 18 or 22 days, at the end of which time another series is administered. In myoma cases five to six series are commonly used.

In gynecological cases, patients were treated for one or two days at intervals of eighteen to twenty-four days, covering a period of sixty to one hundred days. Amenorrhœa was obtained within one month after treatment was begun.

The utilization of the Gauss technique will be more readily accepted for inoperable malignant conditions than for gynecological conditions. As to whether it should be used in the latter field must be determined by the gynecologist. The duration of the treatments seems to be needlessly tedious. They can be greatly shortened by increasing the size of the areas of the skin that are treated at one time.

The publication of brilliant results with such enormous dosages given by Gauss was liable to dangerously stimulate the widespread treatment of disease by men who do not measure their dosages of X-rays. "The slogan of success in röntgen therapy is the same as that of any specialty technique."

MILITARY AND NAVAL SURGERY

Wolf, W.: Periostitis from Over-Exertion and Spontaneous Fractures in the Army (Über Anstrengungsperiostitis und Spontanfrakturen in der Armee). *Deutsche mil.-ärztl. Ztschr.*, 1913, xlii, 548.
By Zentralbl. f. d. ges. Chir. u. i. Grenzgeb.

Periostitis from over-exertion occurs only in the lower extremities, on the inner surface of the tibia and the femur. Soldiers complaining of pains in the femur were often accused of simulating because a periostitis could not be diagnosed on account of the thickness of the soft parts of the thigh. To-day the röntgen examination explains such cases.

The author reports the case of a soldier who complained repeatedly after long marches of pains in both thighs. Examination yielded no objective findings. The röntgen examination, however, revealed periostitic stratifications on the inner side of the femur.

Chronic inflammation of the periosteum causes defective nutrition in the bones which results in abnormal brittleness. Periostitis from over-exertion is therefore an important factor in the frequency of spontaneous fractures of the lower extremities in the army. The author reports in detail also a case in which a suspected fracture from periostitis was ascertained by the X-ray.

SIMON.

Stierlin and Vischer: Experiences with the Mastisol Bandage in the Servian-Turkish War (Erfahrungen mit dem Mastisolverband im serbisch-türkischen Krieg). *Cor.-Bl. f. schweiz. Ärzte*, 1913, xliii, 688.

By Zentralbl. f. d. ges. Chir. u. i. Grenzgeb.

Stierlin and Vischer were active in the reserve hospital at Belgrade and in a field hospital at Monastir at the battle of Monastir. At these places they used aseptic vioform gauze directly on the wounds, sealed it with mastix solution and put an ordinary piece of bandage over it. Infection was prevented by this method, even during transportation of the wounded. The severely lacerated and crushed wounds were dressed with ordinary gauze. Much time and material were saved by employing the mastisol bandage. Their solution consisted of 40 gm. mastix, 100 gm. benzol and 40 drops of linseed oil.

GEORG SCHMIDT.

GYNECOLOGY

UTERUS

Kelly, H. A., and Neel, J. C.: **Carcinoma of the Cervix of the Uterus.** *Bull. Johns Hopkins Hosp.*, 1913, xxiv, 231.
By Surg., Gynec. & Obst.

This article deals with the ultimate results, as far as they could be obtained, of all cases of carcinoma of the cervix observed in the gynecological clinic of the Johns Hopkins Hospital from 1900 to 1911—137 cases in all. A resumé is given of the clinical history, treatment, findings at operation, primary mortality, late results, and absolute accomplishment.

The authors draw the following conclusions:

1. The extensive abdominal removal of all uterine cervical carcinomata is justified where there is any hope of complete excision, unless there is some special contra-indication to surgical interference. This operation, if properly performed, has given, notwithstanding the high primary mortality, the greatest percentage of permanent cures of any therapeutic measure thus far suggested.

2. An exploratory operation is often necessary to determine whether or not a case is operable.

3. Obesity is not necessarily a contra-indication to the operation, since the wide horizontal lipectomy decreases the depth of the field of operation.

4. The preliminary catheterization of the ureters is a valuable aid, especially in fat patients, and does not necessarily increase the probability of fistulae and secondary infection of the urinary tract.

5. Decreased cervical mobility is sometimes due to a secondary inflammatory reaction and may be improved by cauterization of the primary growth.

6. Preliminary cauterization and disinfection of the primary growth are advisable in all cases.

7. Extensive glandular dissection is not justified, since the increase in permanent cures does not compensate for the rise in the percentage of the primary mortality.

8. By improvements in the technique of the operation, the primary mortality has been decreased from 28.5 per cent for the first seven years to 11.5 per cent for the last five years. Further simplification and perfection of the details of this operation may yet reduce the primary mortality to nearly that of the ordinary laparotomy and make it more generally available.

Aside from the discovery of the etiological factor of carcinoma of the cervix of the uterus and its successful elimination, the greatest hope lies in the early recognition of the primary growth. This can be accomplished only by a more thorough training of the family physician as to the symptoms and signs of cancer and by a systematic education of the laity.

GEORGE E. BEILBY.

Klein, G.: **Results Obtained with X-Ray Treatment of Carcinoma of the Uterus, Ovaries, and Mammæ** (Erfolge der Röntgenbehandlung bei Carcinom des Uterus, der Ovarien und der Mamma). *Deutsche Gesellsch. f. Gynäk.*, Halle, 1913, May.
By Zentralbl. f. d. ges. Gynäk. u. Geburtsh. s. d. Grenzgeb.

From 1904 to 1907 the author treated six cases of carcinoma of the uterus with the X-rays. The principal results were that the tumors were prevented from spreading and the pains and decomposition decreased during the treatment. The connective tissue surrounding the tumor became firmer and acted as a wall through which the tumor did not spread. With improved apparatus and technique the author induced Drs. Hirsch and Monheim of the Munich polyclinic to treat with X-rays nine patients suffering from inoperable cervix involvement, and twelve patients in whom the carcinomatous uterus had been extirpated, a total of 21 cases. One patient had a Wertheim operation performed in January, 1912, and has had two vaginal recurrences which were excoriated and cauterized. As a result of prolonged X-ray treatment she is now probably free of any recurrence. This is the only case of this kind known to the author. There is no proof that the cure effected is permanent, but at any rate the result is excellent. Those cases which have been operated upon previously are especially adapted for the X-ray treatment, as all carcinomatous rests can be destroyed much more easily than large inoperable tumors. Probably the effect is due to the destruction of the carcinoma organism, as the result of which the surrounding tissue infiltrated with leucocytes is rendered capable of taking care of the tumor rests that remain. Of particular interest was a case of an adenocarcinoma of the breast. The author amputated the breast in 1907, and removed the recurring nodules in 1909, 1910, and 1911. The scar, meanwhile, was treated with X-rays and the last nodule, extirpated in 1912, showed no carcinomatous tissue. In 1913, five and three quarter years after the amputation the patient was still free from recurrences. The results were good also in operable and inoperable ovarian adenomas and carcinomas. In all cases the growth was checked, ascites formed much less frequently, and the tumors became more firm.

Pinkuss, A.: **The Results of Mesothorium Treatment in Carcinoma** (Über die Erfolge der Mesothoriumbestrahlung bei Carcinom). *Berl. klin. Wchnschr.*, 1913, I, 1105.
By Zentralbl. f. d. ges. Gynäk. u. Geburtsh. s. d. Grenzgeb.

Since September, 1911, the author has treated twenty-two cases of genital carcinoma successfully

with mesothorium. The activity of 88 mg. radium bromide proved to be sufficient when the treatment was repeated frequently, and this amount minimized the danger of injuring neighboring parts. After prolonged exposure the surface cancer cells become degenerated, but deep-lying nodules were not influenced and metastasis was not prevented.

Success depends upon the degree of the malignancy of the cancer, the general constitution of the patient and his tendency to become cured. Frequently cessation of the growth was produced by mesothorium, but later more rapid extension occurred. Abdominal exposure demands great care and experience. Tumors lying near the abdominal wall are difficult to influence. Vaginal treatment is much more simple, but in this case the great danger lies in producing injury to neighboring organs, the bladder, the ureter, the bowel, and the uterine artery. All operable cases upon which for some reason operation cannot be performed are adapted to this treatment as well as inoperable cases or recurrences. Radical operations, followed by prophylactic exposure to mesothorium is especially to be advised. Mesothorium combined with the deep penetrating X-rays and intravenous atoxyl injections, is excellent.

MONHEIM.

Gunakoff, L.: The Question of Cystic Degeneration of Uterine Myomas (Zur Frage der cystischen Degeneration der Uterusmyome). *Ztschr. f. Geburtsh. u. Gynäk.*, 1913, xxviii, 715.

By Zentralbl. f. d. ges. Gynäk. u. Geburtsh. s. d. Grenzgeb.

The patient was a woman 39 years of age. She had had one spontaneous delivery and one abortion. For over a year the menses were regular yet much more profuse than before, and she complained of general weakness. For several months hæmorrhage persisted without ceasing, the abdomen became enlarged, and the general weakness increased. Examination showed a tumor arising from the uterus or the ovary. At operation an elastic tumor the size of a child's head was found. It was multilobular and excentrically developed and was situated in the mesometrium on the right uterine wall. The patient recovered.

Examination of the tumor showed it to be a myoma with cystic degeneration. Microscopically the tumor tissue was different from the smooth musculature of the uterus. It consisted of cells with round or oval nuclei and the stroma was poorly developed. Several places still showed isolated strands of smooth muscle fibers and connective tissue bundles.

The cause of the degeneration was poor nutrition, such as occurs in thin-pediced, subserous, or intraligamentous myomas. The symptoms of such degeneration are not constant. According to Winter, severe hæmorrhage occurs in 74 per cent of the cases. The growth is not rapid. Hæmorrhage, enlargement of the abdomen, general weakness, and the danger of sarcomatous degeneration are indications for operation.

GINSBURG.

Langes: Experiences with the X-Ray in the Treatment of Myomas and Metropathies (Erfahrungen mit der Röntgenbehandlung bei Myomen und Metropathien). *München. med. Wchnschr.*, 1913, lx, 1740.

By Zentralbl. f. d. ges. Gynäk. u. Geburtsh. s. d. Grenzgeb.

Twenty-four cases of uterine myomas and fifty cases of hæmorrhagic metropathies were treated with the X-ray. The technique at first was that of Albers-Schönberg. Later, 3 to 4 mm. aluminum filters were employed, and three fields in the lower abdomen and in the sacral region were exposed. In severe cases the perineal and vaginal fields were radiated, a lead glass tube being employed for the vaginal application.

No severe injuries were observed, but skin pigmentation was frequent. "Intoxication" phenomena were extremely mild. There was no diarrhoea and symptoms of ovarian insufficiency were not marked. Of the fifteen cases of myomas carefully observed, eight resulted in amenorrhoea, six in oligomenorrhoea, all of these fourteen showing definite retrogression of the tumor. The fifteenth case resulted in failure due to imperfect technique. Of the thirty-nine cases of metropathies, thirty-four resulted in amenorrhoea, nine in oligomenorrhoea, six remained unchanged, and one was aggravated so that a vaginal total hysterectomy had to be performed. All of the seven failures must be attributed to the insufficiently developed technique that was employed at first. With the present technique no failures have occurred. Improvement began after two or three series of exposures.

RUNGE.

Pinkuss, A.: Mesothorium in the Treatment of Hæmorrhagic Metropathies and Myomas (Die Mesothoriumbehandlung bei hæmorrhagischen Metropathien und Myomen). *Deutsche. med. Wchnschr.*, 1913, xxxix, 1041.

By Zentralbl. f. d. ges. Gynäk. u. Geburtsh. s. d. Grenzgeb.

The mesothorium treatment of hæmorrhagic metropathies and of hæmorrhages due to myomas is a valuable addition to our therapy. Similar to the action of the X-rays, the hard rays of mesothorium produce a gradual atrophy and sclerosis of the ovarian tissue and therefore, indirectly, an oligomenorrhoea or an amenorrhoea. A direct influence upon the uterine wall or upon the tumor has not been demonstrated and is not essential.

The method of applying the treatment is of advantage to the physician as well as to the patient; the mesothorium is placed into the vagina in little capsules and exerts its influence upon the ovaries from there. The author has not employed the intra-uterine application, as with that method the rays must first penetrate the uterine wall and consequently are weakened. Furthermore, he does not consider a direct effect upon the uterus and tumor necessary.

The treatment is indicated in those cases in which no improvement follows curettement and cauterization. Malignant degeneration of course must be

excluded by a careful histological examination. Patients approaching the menopause (30 years of age and upwards) are the best subjects since the reproductive functions are injured. The symptoms incident to ovarian atrophy are about the same as those that occur after operative castration, and are mild. The author believes that this new method will supplant operative procedures. HARF.

Bukojemsky, F. W.: Uterine Sclerosis, Arteriosclerosis Uteri, and Its Relation to Uterine Hæmorrhage (Die Gebärmutter-sklerose, Ateriosclerosis uteri, und deren Zusammenhang mit den Uterus-blutungen). *Arch. f. Gynäk.*, 1913, xcix, 463.

By Zentralbl. f. d. ges. Gynäk. u. Geburtsh. s. d. Grenzgeb.

The author discusses the difference between infectious metritis and sclerosis uteri, both of which may cause profuse metrorrhagia and are characterized by abnormal enlargement of the body of the uterus. In infectious metritis, however, the inflammatory process is seen chiefly in the uterine tissue without participation of the blood vessels, while in sclerosis, the periarterial processes are involved. In the history of the cases, hereditary signs of chronic arthritis, rheumatism, etc., and past infections are met with. In uterine sclerosis special attention must be paid to the condition of the blood vessels, which show arteriosclerotic changes in typical form, and to the changes and diminution in the quantity of the elastic structures of both the uterus and the blood vessels.

The dependence of uterine hæmorrhage upon arteriosclerosis uteri has not been generally recognized, but the majority of the investigators are of the opinion that the changes in the vessels play the chief rôle. Differences of opinion still exist as to the condition of the elastic tissue in arteriosclerosis. All investigators, however, agree that it increases in amount. A minute description of three cases observed by the author is given. In these the uterus was extirpated on account of uncontrollable hæmorrhages. In all three cases the typical picture of the so-called sclerosis uteri or its vessels were found and also necrosis of the vessel walls. The author considers the hæmorrhage a result of the changes in the vessels due to the disappearance of the elastic elements in their walls. MARKUS.

Ziegenspeck: Chronic Parametritis and Displacements (Parametritis chronica und Lageveränderungen). *Deutsche Gesellsch. f. Gynäk.*, Halle, 1913, May.

By Zentralbl. f. d. ges. Gynäk. u. Geburtsh. s. d. Grenzgeb.

Ziegenspeck expresses himself as opposed to the view recently expressed that there is no such thing as parametritis chronica and that such conditions are really due to chronic peritonitis. He points to the parametritis acuta puerparalis of Virchow which frequently develops into the chronic form. He mentions also the work of König, Rosthorn, Freund, and his own work, and refers further to the older points in the differential diagnosis between para-

metris chronica and peritonitis mentioned by Schulze. To the latter he adds three new points: (1) an apparent downward bulging of the vaginal vault on the affected side; (2) a movability of the fixed uterus in the direction of the diameter of the pelvis in parametritis, whereas in chronic peritonitis the movability is more in the direction of segments of a circle, and (3) the fact that the parametric induration can be seen with the aid of a grooved speculum.

In regard to treatment, ventrofixation according to the method of Broese is too uncertain and too formidable a procedure. Fränkel proposed lengthening the fold of Douglas by implanting into it peritoneum from the omentum. To cure an induration of connective tissue he does the same thing as is done when a piece of skin is implanted for the correction of Dupuytren's contraction of the palmar aponeurosis. Massage and stretching is etiologically the correct method and cure results in a short time.

Rusoakova-Snowitsch, A. A.: Mud and Mineral Baths during Menstruation (Schlamm- und Mineralbäder während der Menstruation). *Ztschr. f. Geburtsh. u. Gynäk.*, 1913, xxviii, 783.

By Zentralbl. f. d. ges. Gynäk. u. Geburtsh. s. d. Grenzgeb.

The author reports the results of the employment of warm and hot baths in 110 cases during menstruation. Eighty were cases of dysmenorrhœa. Her conclusions are as follows:

1. Mud baths, warm or hot, regulate the bleeding. The duration of the period is not influenced very much, and is shortened rather than prolonged.
2. The pains either cease entirely or are much decreased.
3. The general condition is not influenced unfavorably.

According to Strassburger, the favorable influence exerted by the baths is due to the fact that they irritate the skin and in this way produce a contraction of the peripheral blood vessels. The contraction soon disappears and is followed by a dilatation of the blood vessels of the skin and a contraction of the vessels of the internal organs. GINSBURG.

Sweeny, T. T.: Leukoplakia Uteri. *Am. J. Obst.*, N. Y., 1913, lxviii, 243. By Surg., Gynec. & Obst.

The author reports in detail a rare case of leukoplakia of the cervix, giving the history and the pathology, and gross and microscopical drawings. He also reviews the subject with reference to the eight cases that have been previously reported in the literature. He draws attention to the tendency of leukoplakia to cancerous change and in cases of leukoplakia of the cervix, advises early and complete excision of the affected area. N. SPROAT HEANEY.

Rieck, A.: The Indications for and Technique of Defundatio Uteri (Zur Begründung und Technik der Defundatio uteri). *Frauenarzt*, 1913, xxviii, 242. By Zentralbl. f. d. ges. Gynäk. u. Geburtsh. s. d. Grenzgeb.

Oblique resection of the body of the uterus is an operation for the relief of profuse menstrual periods

and is called defundatio uteri. The author emphasizes his priority in devising the operation. The advantages of this procedure over that of total extirpation are: (1) the much shorter time necessary to perform it, 20 to 45 minutes, and (2) the much simpler technique. The size of the uterus, adhesions, and even pyosalpinx, need not contra-indicate it. The extraperitoneal method is to be preferred. By it peritoneal irritation and the other disturbances that follow total extirpation are avoided. The stump into which but few ligatures are placed causes no peritoneal irritation, but suppurative or fetid inflammation of the extraperitoneal wound does occur. The principal advantage lies in the fact that menstruation is maintained whereas in total extirpation amenorrhoea ensues. Uninterrupted recovery is the rule. SCHROEDER.

ADNEXAL AND PERIUTERINE CONDITIONS

Heimann, F.: The Internal Secretion of the Ovaries and Its Relation to the Lymphocytes (Innersekretorische Funktion der Ovarien und ihre Beziehungen zu den Lymphocyten). *Ztschr. f. Geburtsh. u. Gynäk.*, 1913, lxxiii, 538.

By Zentralbl. f. d. ges. Gynäk. u. Geburtsh. s. d. Grenzgeb.

The thymus has the power to increase, and the ovaries, the power to decrease the number of lymphocytes. An increased internal secretion of the ovaries leads to a decrease in the number of lymphocytes, and a diminished secretion, to an increase in the lymphocytes. Heimann determined that in the intermenstruum the normal number of small lymphocytes is from 18 to 22 per cent and that during menstruation the number is considerably increased. An increased number of lymphocytes is found also in processes which cause hypoplasia, or a disturbed function, of the ovaries, such as amenorrhoea and the climacterium. However, after the menopause has existed for some time a decrease is noted. Cases of inflammatory adnexal disease which are accompanied by fever can not be used in these investigations. In afebrile adnexal disease, the number of lymphocytes decreases, and in ovarian tumors it increases. The number can be markedly lowered by the use of ovarian extract. BONDY.

Kloss, H.: A Case of Sarcoma Developing Within a Teratoma of the Ovary with Metastases in the Great Omentum (Ein Fall eines in einem Teratom des Ovariums entstandenen Sarkoms mit sarkomatöser Metastase im grossen Netz). *Zentralbl. f. allg. Pathol. u. pathol. Anat.*, 1913, xxiv, 482.

By Zentralbl. f. d. ges. Gynäk. u. Geburtsh. s. d. Grenzgeb.

Most of the sarcomas involving ovarian teratomas have originated within the ovary and invaded the teratoma secondarily. Sarcomas developing within a teratoma are of much rarer occurrence.

The author reports a case belonging to the latter class. The tumor was the size of a child's head and consisted of a unilocular cyst inside of which at four different places little tumor nodules were developing. The metastatic tumor found in the omen-

tum was the size of a man's head, firm and solid. Microscopically the walls of the cyst showed the picture of a genuine teratoma, and the isolated nodules, the picture of a spindle-celled sarcoma. The metastatic tumor showed the same structure as the primary tumors. EBELER.

Ulesko-Strogonoff: Carcinomatous Degeneration of Ovarian Cysts (Zur Frage der carcinomatösen Degeneration vom Ovarialcystom). *Russk. Vrach.*, St. Petersburg, 1913, xii, 604.

By Zentralbl. f. d. ges. Gynäk. u. Geburtsh. s. d. Grenzgeb.

During the last four years two hundred and two ovarian tumors have been operated upon in the Gynecological-Obstetrical Institute of St. Petersburg. Ten were solid tumors and one hundred and ninety-two were cystic tumors. Of the latter, eighty-six were simple cysts, thirty-one, cystic embryomas, fifty-three, proliferating cysts, and twenty-two carcinomatously degenerated cysts. Thirty-three of the proliferating cysts were glandular, and twenty, papillary. In the opinion of the author, the carcinomatously degenerated cysts originated from the proliferating cysts.

From his examinations of these cysts the author draws the following conclusions: (1) Proliferating cystic tumors are transitional forms between benign tumors and tumors undergoing carcinomatous degeneration; (2) the epithelial hyperplasia which characterizes these forms shows this tendency toward malignant degeneration; (3) the relation of the proliferating cystic tumors to the malignant cystic tumors proves the origin of the latter; (4) in the cysts showing carcinomatous degeneration, proofs are evident that they have developed from pre-existing proliferating cysts. BRAUDE.

Baisch: The Removal of Blood from the Peritoneal Cavity Following Rupture of the Tube (Zur Behandlung des bei Tubenruptur in die Bauchhöhle ergossenen Blutes). *Monatschr. f. Geburtsh. u. Gynäk.*, 1913, xxxvii, 714.

By Zentralbl. f. d. ges. Gynäk. u. Geburtsh. s. d. Grenzgeb.

Baisch recommends the complete removal of all blood from the peritoneal cavity in cases of hæmorrhage following a rupture of the tube. It should be allowed to remain only in those cases in which the patient's condition demands a hurried operation. He considers the presence of blood in the peritoneal cavity as an added factor in the development of peritonitis, since blood is an excellent culture medium. It aggravates the subjective symptoms during convalescence and increases the danger of post-operative adhesions. ZINSSER.

Hannes, W.: Affections of the Adnexa: Inflammations and Tubal Pregnancy (Die Adnexerkrankungen: Entzündungen und Eileiterschwangerschaft). *Ergebn. d. Chir. u. Orthop.*, 1913, vi, 609.

By Zentralbl. f. d. ges. Gynäk. u. Geburtsh. s. d. Grenzgeb.

This article is based upon observations made at the gynecological clinic in Breslau. As causes of

the inflammations of the adnexa were found the gonococcus, streptococcus, staphylococcus, diplococcus lanciolatus, bacterium coli, bacillus typhosus, the tubercle bacillus, actinomyces, and Friedlander's bacillus. Fifty per cent of the cases were due to the gonococcus and only four and one half per cent to the tubercle bacillus. Hannes believes that when adnexal inflammation is accompanied by appendicitis the latter is secondary to, and not the cause of, the former. According to the pathological anatomy he classifies adnexal inflammations into two large groups: (1) Those with exudate formation in the lumen of the tube and the formation of lactosalpinx. (2) Those with peritubal inflammation and the formation of numerous adhesions. The latter form is often only a late stage of the former.

In discussing the diagnosis the author recommends puncture of the pouch of Douglas, but this should be done only when there is no suspicion of the presence of tuberculosis. The preparation of a gonococcus vaccine he expects will be of great value in the differential diagnosis. The local reaction following the injection of old tuberculin is also of great diagnostic value. He discards and advises against curettement for diagnostic purposes as non-tuberculous affections of the adnexa may react violently to such procedure.

Hannes believes with Küstner that fresh inflammatory conditions are a *noli tangere* for operative interference and that the later a chronic inflammatory condition is attacked surgically, the more conservative need the operation be, and the better and more permanent the results. After nine to twelve months a closed sactosalpinx will have become sterile. If the conditions demand an interference during the acute stage the abdominal route is to be preferred, as it permits a more conservative operation. The author attributes particular value to the V-shaped excision of the uterine ends of the tube and careful suture of the same in case the uterus can be saved; in other cases, and when there is much adhesion, the methods of Faure, Kelley, and Beuttner, with previous hemisection of the uterus, greatly facilitate the resection of the adnexa from this point. For drainage purposes, which is indicated only in tuberculosis, the author employs the tampon through the lower angle of the abdominal wall in cases in which the presence of infectious pus is suspected, or in which oozing takes place. In cases in which the fimbrial extremity is closed only by the formation of adhesions around the tube, he advises the salpingostomatoplastic operation to permit the possibility of a later pregnancy.

In discussing tubal pregnancy the author advises the employment of puncture of the pouch of Douglas for the differential diagnosis of hæmatocele and perforative appendicitis. In cases of internal hæmorrhage he advises immediate laparotomy, even in collapse, with careful removal of all blood. Even if there is no internal hæmorrhage, he

recommends operative treatment in all cases of unruptured tubal pregnancy, in ruptured pregnancy, and in hæmatocele in which there is recurrent hæmorrhage and in suppurative hæmatocele. The resection of the other tube to prevent a recurrence of ectopic pregnancy is not deemed justifiable; on the contrary he advises the salpingostomatoplastic procedure on this tube also, that a later uterine pregnancy may be possible.

VASSMER.

EXTERNAL GENITALIA

Bondy, O.: Vaginal Bacteria and Endogenous Infection (Scheidenkeime und endogene Infektion). *Ztschr. f. Geburtsh. u. Gynäk.*, 1913, lxxiii, 604.

By Zentralbl. f. d. ges. Gynäk. u. Geburtsh. s. d. Grenzgeb.

The author attacks principally the views of Bumm and Sigwart in regard to endogenous infections. A strict separation of the germs of the external genitalia from those of the vagina is impossible. He disputes the statement that saprophytes are not to be found in women who have not been subjected to vaginal examination. He does not recognize the teachings of Bumm and Sigwart concerning the apathogenity of the vaginal streptococci on account of their defective animal virulence. The question of self-sterilization of the vagina should be entirely dropped, for as soon as the endogenous infection commences during labor, at the time of the rupture of the amniotic sac the power of self-disinfection of the vagina ceases on account of the changed composition of the vaginal secretion.

BENTIN.

Jack, W. R.: Vaccine Therapy in the Treatment of Gonococcal Vulvo-Vaginitis. *Glasgow M. J.*, 1913, lxxx, 84.

By Surg., Gynec. & Obst.

In the cases treated by the author the results obtained were as follows: A cure was effected in three cases, in the first two after two and a half months of treatment, and in the third, after over three months of treatment. In another three cases the condition remained uncured, in one case after two months of treatment, in another after five months, and in the third after more than five months.

The results in this short series were disappointing although there was a marked lessening of the discharge and a freedom from the irritation which is often found when vaccines are not used. The very favorable reports which have been given by some authorities have not been corroborated by other investigators. In the Vanderbilt clinic two hundred and sixty cases were treated by the irrigation method and eighty cases by vaccines. The percentage of recoveries was sixty with the former method and ninety with the latter. The time required for cure was 10.1 months with the irrigation method, and 1.7 months with the vaccine method. These statistics are very encouraging, but the author hesitates to accept them, since other authorities give no such

encouraging reports. The most that the author claims for the vaccine treatment in cases of vulvovaginitis in children is that it causes a marked amelioration of the symptoms and a lessening of the discharge.

J. H. SKILES.

Hofmann, O.: The Iodine Treatment of Gonorrhœa in the Female. *Interst. M. J.*, 1913, xx, 733. By Surg., Gynec. & Obst.

In the acute cases a smear is made from Skeen's glands and the urethra, and several from the vagina and the vulvo-vaginal glands. When the cause of the infection is found the labia are separated and the parts exposed swabbed with a solution of 3.5 per cent iodine crystals in 95 per cent alcohol. Next, a few drops of the solution are injected into Skeen's glands and the vulvo-vaginal glands by means of a hypodermic syringe with a blunt needle. The vagina is then swabbed with the patient in the Sim's position and with the aid of a Sim's speculum. A strip of gauze is next introduced.

In protracted cases in which the cervix and uterus are involved, the cervix is first painted and then a drachm of the iodine solution is injected under low pressure into the uterine cavity. This is repeated four or five times every three days.

In all cases copious hot douches are given, followed by a 1:5000 permanganate solution. The bowels are kept open by catharsis. Tea, coffee, and alcohol are forbidden.

EUGENE CARY.

MISCELLANEOUS

Cullen, T. S.: Address in Gynecology. *Canad. M. Ass. J.*, 1913, iii, 658. By Surg., Gynec. & Obst.

The author presented this paper to urge the medical profession to bring before the laity the necessity of an early operation in cancer. That the campaign which has already been started has yielded results is shown by the communications the author has received from different surgeons. He states that it is the duty of the medical profession to impress upon the laity the fact that cancer is a local process which can be cured if taken early enough. He believes that the same change of attitude can be brought about in regard to cancer as obtains now in regard to appendicitis. Twenty years ago it was difficult to persuade a person to be operated for appendicitis. To-day, when the diagnosis has been made, the first question is, "To what hospital shall I go?"

The author next discusses the diagnosis of cancer of the skin, lip, tongue, stomach, intestine, rectum, breast, and uterus, touching upon them lightly. He quotes two cases in detail of myomata of the uterus with adenomyoma of the cervix and rectum, associated with rectal adhesions and adenoma of the left broad ligament intimately connected with the rectum.

He urges the practitioner to become well informed in regard to the pathological and anatomical structure of the part affected, so that it will be possible for him to know the paths along which the cancer

usually travels. It would be folly to operate a case of cancer of the rectum if the liver were involved.

Cullen further urges that hospitals become more business-like in their methods; also that cases be followed so that the result of the cancer operations can be definitely known. He suggests that a special clerk be assigned to follow up cases of this kind and report the results of the operations.

EDWARD L. CORNELL.

Pfahler, G. E.: Röntgenotherapy in Gynecology. *Tr. Am. Röntg. Ray Soc.*, Boston, 1913, Oct.

By Surg., Gynec. & Obst.

Röntgenotherapy in gynecology is now recognized as a valuable factor in the treatment of uterine fibroids, uterine hæmorrhage of metropathic origin, and a number of other affections to a lesser extent.

The author's experience in the treatment of fibroids, limited to 27 cases, extended over a period of ten years. The greater number of cases occurred during the past seven years. The results were most satisfactory in that a menopause was produced, the hæmorrhages were controlled, and the tumor gradually disappeared. In some instances the tumor continued to disappear long after the treatment had been stopped.

The treatments were given in series, each series involving a full dose administered through four different areas of the skin. When circumstances demand it, these four areas can be treated either in one day, or on four different days. The treatment is then not repeated until three weeks have elapsed. A cure usually requires from four to six such series of treatments.

The following conclusions were drawn:

1. Röntgenotherapy is the method of choice for hæmorrhage in patients approaching the menopause in whom carcinoma can be eliminated.
2. It is not the method of choice in patients under forty years of age.
3. It can be recommended in all cases of any age in which operation is contra-indicated.
4. For the differential diagnosis, in order to determine the indications for this treatment, special skill in gynecology is required; and for the proper administration of the rays, special training in röntgen technique is necessary. It is possible for a gynecologist to become a röntgenologist; it is also possible for a röntgenologist to become a gynecologist, but it is very unlikely that either one will master both. Therefore, the author believes that each case should be examined by a gynecologist and treated by a röntgenologist.

Heinsius, F.: The Cystoscopical Diagnosis of a Ureteral Calculus and the Removal of It by the Vaginal Route (Über die cystoskopische Diagnose eines Uretersteins und seine Entfernung auf vaginalem Wege). *Ztschr. f. Geburtsh. u. Gynäk.*, 1913, lxxiii, 441.

By Zentralbl. f. d. ges. Gynäk. u. Geburtsh. s. d. Grenzgeb.

In a 47-year-old female patient, who was taken ill with right-sided colic and chills, a calculus in the

lower portion of the ureter was diagnosed by means of cystoscopic examination. The stone was removed by the vaginal route by exposing the ureter in the left parametrium and incising it. Uninterrupted recovery resulted.

BOXER.

Squier, J. B.: The Modern Diagnosis and Treatment of Gynecological and Obstetrical Patients with Syphilis. *N. Y. M. J.*, 1913, xcvi, 357.
By Surg., Gynec. & Obst.

The author dwells upon the biological diagnosis of syphilis in gynecological and obstetrical patients by the complement fixation and luetin skin reactions and provocative salvarsan administration. The consideration of greatest importance is the experience and dependability of the biologist who conducts the tests. The value of clinical evidence as well as the worth of diagnostic treatment should not be lost sight of when such evidence conflicts with laboratory tests. Treatment should be initiated as soon as a diagnosis has been made. Squier uses neosalvarsan almost entirely.

Neosalvarsan has the following advantages in comparison with salvarsan: (1) It is more simple to prepare; (2) it minimizes the number of preparation ingredients, thereby reducing the possibility of faulty technique; (3) it does not require as large a volume of fluid for injection.

Conditions necessitating caution in the administration of neosalvarsan are chronic alcoholism, myocarditis, arteriosclerosis, and lesions of the cerebrospinal system. The neosalvarsan medication is supplemented with an intensive mercurial treatment continued in earlier cases from six months to a year, and in later cases for a somewhat longer period.

The author sums up his conclusions as follows: (1) Treatment should be begun the moment diagnosis is certain; (2) to insure success it must be as intensive as regards the administration of both arsenic and mercury as the history of the case and the patient's physical condition will warrant; (3) under no circumstances should the physician attempt to treat a disease of such widespread effect and sinister influence without having given much study to the present conception of the management of the disease.

HENRY SCHMITZ.

Sigwart, W.: Bacteriological Control of Asepsis During Gynecological Laparotomies (Die bakteriologische Kontrolle der Asepsis bei gynäkologischen Laparotomien). *Arch. f. Gynäk.*, 1913, xcix, 284.

By Zentralbl. f. d. ges. Gynäk. u. Geburtsh. s. d. Grenzgeb.

The bacteriological control was extended at Bumm's clinic so that not only a bouillon culture was used in the "three-sponge test," but the number of germs present was approximately determined by cultures on agar plates. This control was carried out in 114 major abdominal operations. In 86 per cent of the aseptic operations the bacterial content was small. Streptococci were found only twice; air

bacteria in all other cases. Numerous germs were always obtained from septic operations, the staphylococcus albus and aureus and the bacillus coli predominating. Streptococci were found twenty-three times in seventy-one cases. This difference was plainly marked in the healing of the wound. Not a single disturbance in the course of healing was observed in spite of the presence of streptococci. A positive prognosis as to wound repair cannot be made from the bacteriological findings at the time of operation. The investigations, however, justify the conclusion that the healthy peritoneum accommodates itself to a relatively large number of weak virulent germs. Connective tissue wounds must be carefully dried from blood, all bleeding and oozing must be arrested, and all wounds must be carefully covered with healthy peritoneum, the visceral coat being used eventually for this purpose.

LHOTZKY.

Jellett, H.: The Surgical Treatment of Pelvic Thrombosis of Septic Origin. *Surg., Gynec. & Obst.*, 1913, xvii, 147.
By Surg., Gynec. & Obst.

The treatment of puerperal pyæmia is of such importance that any procedure that offers any hope of an improved mortality rate is worthy of consideration. The author, having seen in the post-mortem room apparently operable cases of pelvic thrombosis the result of pyæmia, decided to operate on similar cases in future. In the article he records three cases of this kind in all of which the initial history was characterized by recurrent rigors, high temperature, and rapid pulse.

In the first case, on the fifteenth day a swelling was found in the right broad ligament. He opened the abdomen and removed a large thrombosed and suppurating ovarian vein, round which was a considerable amount of cellulitis. The patient rapidly improved.

In the second case he did not operate until the thirty-ninth day, as owing to absence from the hospital, he had not seen the patient before. In this case he removed a tense, cord-like structure, which turned out to be a thrombosed ovarian artery, and he also removed the ovarian vein, which contained a small thrombus in its lower part. The patient had a few rigors after the operation, but they disappeared, and her temperature fell to normal and remained so.

In the third case a very similar condition to that met with in the first was found at operation, except that it had gone much further. Septic peritonitis was on the point of starting, the whole length of the ovarian vein contained pus, and there were two abscesses beside the vein. The patient improved for a few days after the operation, then gradually lapsed, until on the thirteenth day after confinement she was as bad as before the operation. A hysterectomy was performed. The patient improved temporarily, but rapidly became again seriously ill, and died on the thirty-fifth day with symptoms of septic involvement of the lungs.

The author describes also two cases of pyæmia without obvious thrombosis. In the first case he performed a hysterectomy but without benefiting the patient. In the second case he tied the ovarian veins, and recovery began at once and continued.

In conclusion, the author refers to the interesting fact that in all of his cases the thrombosis was on the right side, and primarily in the ovarian vein alone. He considers that such cases always call for operation, and that it should be performed as early as possible to anticipate conditions such as were found in the third case. He considers that the diagnosis is the important point, and that, as a rule, it can be made from the symptoms of the patient, taken in connection with a thickening or swelling in the broad ligaments or along the course of the veins not accompanied by much pain.

Lampé: Basedow's Disease and the Genital Organs (Basdowsche Krankheit und Genitale). *Deutsche Gesellsch. f. Gynäk.*, Halle, 1913, May.
By Zentralbl. f. d. ges. Gynäk. u. Geburtsh. s. d. Grenzgeb.

It is evident from the literature and the reports of Frankl and Graff that there are clinical facts which indicate relations between Basedow's disease and the genital organs. Next to the disturbances in menstruation, it is the hypoplastic changes of the genitalia in exophthalmic goiter that are of chief interest to the investigator, and that are interpreted as indicating a decrease in the functioning of the ovaries. Particularly in permanent ovarian hypoplasia we do not know whether there is really a hypofunction, an afuction, or even a dysfunction of the ovary, for the anatomical character of an organ does not permit of a conclusion as to its function. For this reason also the belief in the existence of a relation between Basedow's disease and the ovaries based merely on the clinical facts above mentioned would for a long time have remained mere theory if we had not acquired a method by which we may obtain an insight into these complicated relations and determine an existing ovarian dysfunction positively. This method is Abderhalden's protective ferment reaction, and the theory upon which it is based is as follows: If, in Basedow's disease, the activity of the ovary is qualitatively disturbed, i. e., if the ovary gives off an abnormal substance into the blood stream, the organism as a whole should react to this product of dysfunction, which is foreign to the blood, by producing protective ferments against it. These ferments ought to be detected by the Abderhalden reaction.

Proceeding from this theory, the blood of patients suffering from exophthalmic goiter was examined for protective ferments. The serum of the patients was brought into contact with thyroid gland, thymus, ovary, testicle, kidney, adrenals, and liver.

By the use of the ninhydrin test it was determined which of these organs were split. The thyroid gland was split in all, and the ovaries and thymus in most, of the twenty-five cases of genuine exophthalmic goiter so far examined. The tests with the other organs were always negative. The results of these tests are to be explained as follows: (1) The first abnormal step in exophthalmic goiter is a dysfunction of the thyroid gland. (2) Also in most cases the functioning of the thymus gland and the ovaries is abnormal. In most cases of Basedow's disease it is possible not only to demonstrate the functional changes, but also to determine the nature of the abnormal function. The question now arises as to whether the dysfunction of the ovaries in exophthalmic goiter is primary or secondary. It seems evident that it is a secondary disturbance. The product of a dysfunctionating thyroid gland has ovariotrophic significance, which means that it invades the ovaries and influences the activity so that a dysfunction results. Finally we must refer to the fact that a disturbance of the ovary, is indicated by one of the symptoms of exophthalmic goiter. This is the exaggerated growth in stature of patients suffering from exophthalmia which was first mentioned and studied by Holmgren, and which depends on an abnormally long persistence of the epiphyses. The well-known investigations of Sellheim concerning the influences of castration on the growth of the bones permit us to regard the disturbances of the germinal glands as the cause of the delayed ossification of the epiphyses in the long bones of patients suffering from exophthalmic goiter.

Gengenbach: Precocious Menstruation. *J. Am. M. Ass.*, 1913, lxi, 563. By Surg., Gynec. & Obst.

The report of a case of precocious menstruation is given with a discussion of its probable cause. The patient, a child two years of age, bottle fed, had the first menstrual flow, lasting three days, when 10 months old. Menstruation recurred at intervals of one to three months, most frequently at intervals of six weeks. For a few days before the periods a slight leucorrhœa was noticed. The child was cross and acted as if in pain. The peculiar menstrual odor was very marked. It was necessary for the child to wear napkins during a period of about a week. Its weight was 41.5 lbs. and its height, 39 inches. It had 18 teeth. The circumference of the head was 19 inches. The measurement of the chest below the breasts was 21.25 inches and across the breast, 23 inches. The abdomen at the naval was 22 inches and the pelvis 23 inches. The breasts were noticeably prominent, and there was a growth of hair under the arms and about the external genitalia.

HENRY SCHMITZ.

OBSTETRICS

PREGNANCY AND ITS COMPLICATIONS

Ladinski, L. J.: *The Elastic Area in the Isthmus of the Uterus, a Positive and Early Sign of Uterine Pregnancy.* *Am. J. Obst., N. Y.*, 1913, lxviii, 210. By Surg., Gynec. & Obst.

The author says that by bimanual examination he has invariably found "a change in early uterine pregnancy which consists of a circular area situated in the median line of the anterior surface of the body of the uterus, just above the junction of body and cervix; that is to say, at the isthmus of the uterus, which varies in size according to the duration of pregnancy, and offers to the palpating finger the distinct sensation of elastic fluctuation. It can frequently be made out as early as the fifth week, when the area is only the size of the finger tip, but it can always be felt in the sixth week when it is somewhat larger."

Schottlænder, J.: *The Determination of the Duration of Pregnancy on the Basis of Histological Placental Findings, and the Possible Practical Utility of these Findings. A Reply to Peters' Article with the Same Title.* (Über die Bestimmung der Schwangerschaftsdauer auf Grund histologischer Placentarbefunde und über etwaige praktische Verwertbarkeit dieser Befunde. Eine Antwort auf den gleichnamigen Artikel von Peters. *Zentralbl. f. Gynäk.*, 1913, xxxvii, 806. By Zentralbl. f. d. ges. Gynäk. u. Geburtsh. s. d. Grenzgeb.

The author calls attention to the fact that no previous description of the exact histology of the placenta in its various stages is found in the literature, and adds that his assertions merely pointed out the possibility of determining the age of the foetus by this means. Peters does not take up the differences in the staining qualities of the blood cells, and the author feels confident that the age of the foetus can be estimated in this way. The first to the second month and the third, fourth, fifth, and sixth months can be determined, while probably between the sixth and tenth months differentiation may be fixed by the blood cells. He cites two instances that go to prove that this method may be of aid in forensic medicine.

JONAS.

Gammeltoft, S. A.: *Nitrogen Metabolism During Pregnancy* (Untersuchungen über den Stickstoffwechsel während der Gravidität). *Skandinav. Arch. f. Physiol.*, 1913, xxviii, 325. By Zentralbl. f. d. ges. Gynäk. u. Geburtsh. s. d. Grenzgeb.

The author's investigations made upon pregnant rats, rabbits, dogs, and goats show that pregnancy causes a storage of nitrogen which, on a constant and medium diet, is less than the amount of nitrogen

lost by the maternal organism as the result of the formation of the foetus. Accordingly, at the end of the gestation there is a nitrogen deficit. By over-feeding it was possible to reverse this to a certain degree. Diuresis is increased during pregnancy and the relation of the urea excreted to the total nitrogen is within physiological limits. The output of ammonia, amino acids, polypeptids, and creatin is increased. In the uric acid excretion the variations lie within physiological limits. The hippuric acid excretion is decreased. The cause for the changes in the amounts of nitrogen-containing decomposition products excreted is to be sought in the liver, but in normal pregnancy these changes are so slight that they do not warrant our suspecting pathological changes in the liver.

NOVAK.

McNee, J. W.: *The Cholesterin Content of the Bile During Pregnancy* (Zur Frage des Cholesteringehalts der Galle während der Schwangerschaft). *Deutsche med. Wchnschr.*, 1913, xxxix, 994. By Zentralbl. f. d. ges. Gynäk. u. Geburtsh. s. d. Grenzgeb.

The author had occasion to examine the cholesterol content of the bile obtained in three autopsies made on patients who had died during the fourth, fifth, and sixth months of pregnancy. He employed the method of Windaus modified according to Weston and Kent. He found an average quantity of 0.621 per cent, which is about four times the quantity in the bile of the non-pregnant. This result was due to the fact that the percentage was calculated only on the basis of the liquid of the bile and not the solids. However, as this was the case in all experiments previously conducted, the figures are relatively accurate. In these three cases Laudau was able to demonstrate an increased cholesterol content also in the suprarenals which probably accounts for the hypertrophy of these organs during pregnancy.

HOLSTE.

Kingman, R. A.: *The Pernicious Vomiting of Pregnancy.* *Am. Med.*, 1913, viii, 519. By Surg., Gynec. & Obst.

The author believes that in the vast majority of cases of "pernicious vomiting" there is ante-flexion of the cervix uteri with varying degrees of descent of the uterus upon the pelvic floor, and more or less fixity of the uterus. The latter is due to thickening and contraction of the periuterine cellular tissue especially in the utero-sacral ligaments. The main points of the author's conclusions are as follows:

1. Pregnancy is a physiological process in which nausea and vomiting have no useful, necessary, or normal part. They are, therefore, never physio-

logical, but always pathological and should be prevented or stopped in every case, and at once.

2. Toxæmia plays no important part as a cause of the vomiting of pregnancy, though it is doubtless often present as a result of a common cause, and may be a factor in advanced cases.

3. Neurotic influences greatly increase susceptibility to reflex stimuli.

4. The essential, exciting, and determining cause in all serious cases is a reflex disturbance proceeding from the uterus, usually from the cervix and especially from the region of the internal os.

5. Intelligent treatment based upon this conception of the trouble has resulted in a quick, uniform, and permanent cure in every case during a period of twenty years, regardless of the stage or severity of the case, and provided that the patient was not moribund when first seen.

6. Such results can be obtained by anyone who will fit himself to make an accurate diagnosis of the pelvic condition and to properly carry out the indicated treatment.

The author's treatment follows the general principles advocated by Hewitt. With the waist and lower ribs free, the patient is placed in the knee-chest position and the vagina is distended with air. In very obstinate cases, the finger may be used to supplement the pull of gravity while the patient is in the knee-chest position. The vagina is then packed reasonably full with tampons made of lightly-felted curly wool, and tied at six-inch intervals with a soft twine or linen thread. The first tampon is dipped in a solution of ichthyol or white petrolatum. The vagina is distended uniformly by the air pressure. The wool simply supports the pelvic organs, thus improving their blood supply. The tampon should be removed at the first symptom of discomfort and in any case after twenty-four to thirty-six hours. Hewitt's air ball pessary may be useful in cases which cannot be treated regularly. A small, gentle, cleansing douche may be given safely.

C. H. DAVIS.

Rosenthal, L. B.: Patent Ductus Arteriosus, Report of a Case Complicated by Pregnancy.
Am. J. Obst., N. Y., 1913, lxviii, 252.

By Surg., Gynec. & Obst.

The author reviews the subject of patent ductus arteriosus and reports a case diagnosed as such which successfully withstood pregnancy and Cæsarian section. The clinical report is complete including the fluoroscopic picture, an orthodiagram and electrocardiographic curves, and several pulse tracings.

N. SPROAT HEANEY.

Pankow: The Frequency and Significance of Cardiac Disease During Pregnancy (Häufigkeit und Bewertung der Herzfehler in graviditate).
Deutsche Gesellsch. f. Gynäk., Halle, 1913, May.

By Zentralbl. f. d. ges. Gynäk. u. Geburtsh. s. d. Grenzgeb.

The frequency of cardiac disease during pregnancy can be determined only by systematic ex-

amination of all of the pregnant women of a lying-in hospital and dispensary. Such examinations have been carried out at the Freiburg Women's Clinic and also at the Düsseldorf Women's Clinic in over 5,000 women. The examinations were all made by an internist. Kùpferle in Freiburg investigated especially the question of accidental heart murmurs. He made these examinations before labor and during the puerperium and found that 49.2 per cent of the women had accidental murmurs and 2.8 per cent actual organic disease. Accidental murmurs are not always easy to diagnose. Kùpferle refers to two points in the diagnosis: (1) An increase in the relative cardiac dullness to the left is found in all pregnant women, even in women without murmurs; but an increase towards the right is demonstrated only in organic disease. (2) In organic disease the murmur is different from that of accidental murmurs. In accidental murmurs the first sound is clear, and followed first by a very short intermission and then by the murmur. In organic disease the first sound is partially covered by the murmur, and the latter continues over the greater part of the systole. The accidental murmurs are mostly soft, blowing sounds. There may be also, however, pronounced loud murmurs and not rarely also an accentuation of the second pulmonic sound. The murmurs probably originate in the pulmonary vessels and can be heard most distinctly in the third left intercostal space or over the third rib close to the sternum.

In the significance of cardiac disease, the condition of the myocardium undoubtedly plays an important rôle. However, endocardial disease can not be considered of equal importance, unless it is complicated by myocardial disease. Mitral stenoses are the most unfavorable from a prognostic standpoint because they add a large amount of work to the small blood circulation and therefore more easily bring about a decompensation. In addition, a mitral stenosis labors from its beginning with the small reserve force of the right ventricle. On the other hand, a mitral insufficiency has the large reserve force of the left ventricle behind it. Therefore, aortic valvular diseases, which in the beginning do not impede the small blood circulation, must be generally considered as the more favorable from a prognostic standpoint.

The author gives the following general indications for the artificial interruption of pregnancy, which must of course be applied to each case individually: (1) If a woman suffering from organic heart disease becomes pregnant and if signs of insufficiency of the heart do not appear in the course of pregnancy, then pregnancy should not be interrupted, as in all probability complications are not to be expected intrapartum. (2) If signs of insufficiency of the heart appear even during the first half of pregnancy, showing that the slight increase in the work of the heart already exhausts the reserve force, then pregnancy should be interrupted in all kinds of heart disease, as the increased work

placed on the heart towards the end of pregnancy and during labor may lead to a sudden failure of the heart. This applies especially to those cases in which the signs of decompensation existed before the occurrence of pregnancy. (3) If signs of decompensation appear towards the end of pregnancy, then the latter must be interrupted in mitral stenosis, especially if marked signs of a severe myocardial disease are present. The treatment is expectant in mitral insufficiency if signs of decompensation permanently disappear after a corresponding treatment. If the signs of decompensation continue to exist, or if they immediately recur after interruption of the treatment, then it is preferable to interrupt the pregnancy through vaginal section considering the increase in the amount of work put on the heart by labor. The frequent complication of mitral stenosis and insufficiency may render the procedure considerably difficult. (4) If signs of decompensation appear during labor then treatment should be expectant if labor is apparently almost terminating, otherwise labor should be cut short by extraction of the child.

Davis, E. P.: The Surgical Treatment of Bacillus Coli Communis Infection Complicating Pregnancy; with Report of Cases. *Tr. Internat. Cong. Med., Lond., 1913, Aug.*

By Surg., Gynec. & Obst.

The writer draws attention to the fact that infection by the bacillus coli communis during pregnancy may cause appendicitis, infection of the pelvis of the kidney usually upon the right side, and, less frequently, cholecystitis.

The diagnosis of infection is made on the basis of the usual signs of resistance in the organism, fever, increased pulse, and leucocytosis.

When infection of the kidney develops, its most significant symptom is a strongly acid urine and the presence of large numbers of the bacillus coli communis in pure culture.

Experience shows that many of these cases recover without operative interference, if rest in bed and liquid food are given and free use is made of water, the milder alkalies, and antiseptic substances. Some cases do not yield to this treatment. Chills and high fever develop and there is soreness or tumor over one or both kidneys. In such cases, surgical interference is necessary.

Davis reports four cases of the latter type that were operated upon during pregnancy. First, the appendix was removed and the wound closed. Next, the right kidney was exposed by the usual loin incision. The kidney was then stitched to the wound by catgut sutures passed through the capsule, the cortex incised, and the gloved finger passed into the pelvis. Dark blood without visible pus exuded, but on examination this blood was found to be swarming with the bacillus coli communis. The kidney was drained by a strip of gauze passed to the pelvis. This drain was gradually removed later.

The four cases reported recovered without the

interruption of pregnancy. The kidney wound gradually closed and the patients went on to spontaneous labor.

While it is obvious that surgical interference is not demanded in all cases, it should be carried out promptly in many.

Engelking, E.: Ectopic Pregnancy in the Ovarian Ligament; a Contribution to the Anatomical Diagnosis of Advanced Cases (Intraligamentär entwickelte Eierstocksschwangerchaft; ein Beitrag zur anatomischen Diagnose vorgeschrittener Fälle). *Monatschr. f. Geburtsh. u. Gynäk., 1913, xxxvii, 740.*

By Zentralbl. f. d. ges. Gynäk. u. Geburtsh. s. d. Grenzgeb.

The author gives a detailed description of an ectopic pregnancy in the ovarian ligament. He found that the tube was obstructed and the foetus was dead. He substantiated his diagnosis by microscopical and macroscopical examinations. He concludes that the ectopic lodgment of the ovum was due to a pelvic peritonitis caused possibly by appendicitis.

JAEGER.

Baldwin, J. F.: Cæsarean Section with Hysterectomy in Cases of Positive Infection. *N. Y. M. J., 1913, xcvi, 372.* By Surg., Gynec. & Obst.

Baldwin cites a case of a primipara, 29 years of age, at full term. She had had pains for two days when the bag of waters ruptured. The pains had entirely ceased and forceps delivery was impossible because the blades would not lock. The patient was exhausted, pulse 130, temperature 104.6° F. The child was large, presented at the brow, and was alive. A Cæsarean section was advised in the interest of the child and a hysterectomy in the interest of the mother. By proper procedure it was hoped to prevent infection of the peritoneal cavity. A low incision was made and the uterus brought entirely out of the abdomen. The abdominal cavity was protected by towels all around. The child was delivered rapidly. In the interior of the uterus a large necrotic patch was found. The uterine cavity was flushed with tincture of iodine which ran down through the cervix into the vagina. A supravaginal panhysterectomy was then completed, except that one ovary was saved. The appendix was removed. The incision was closed without drainage. The temperature fell immediately and the patient made an uneventful recovery.

HENRY SCHMITZ.

Peterson, R.: The Indications for Abdominal Cæsarean Section. *Surg., Gynec. & Obst., 1913, xvii, 198.* By Surg., Gynec. & Obst.

The author discusses some of the more important and common indications for abdominal Cæsarean section. He advocates conservatism in obstetrics and denounces the practice of solving all obstetrical problems by abdominal Cæsarean section. He is of the opinion that with the modern aseptic technique Cæsarean section should, in a measure, take the place of the high-forceps operation.

First, under the heading, "obstructions to labor" the author considers contracted pelvis. He calls

attention to the uncertainty of pelvic measurements and advocates, in moderate contractions of the pelvis, that the patient be given a test of labor. Patients who are undoubtedly infected, due to repeated vaginal examinations and unsuccessful vaginal manipulation, should not have the abdominal Cæsarean section performed. In such cases, craniotomy is preferable. Labor is sometimes obstructed by uterine fibromyomata which may be cervical or intraligamentous in location. The majority of women having fibromyomata do not carry the child to full term because changes occur in the decidua. The Porro Cæsarean section is indicated where fibroids obstruct the canal. Ovarian cysts so located that reduction of the size of the uterus prior to their removal is necessary, form an indication for Cæsarean section.

Stenosis of the cervix and vagina due to scar tissue originating at previous confinements is also discussed. This condition makes spontaneous delivery impossible and artificial dilatation of the scar tissue is dangerous compared to Cæsarean section. Previous ventro- and vagino-fixations of the uterus sometimes give rise to distention and thinning out of the posterior uterine wall during pregnancy. In this case, Cæsarean section is preferable to attempts at delivery from below. At times in a normal uterus the large size of the child offers an indication.

Where a severe concealed accidental hæmorrhage is taking place, the mother's condition alarming and growing worse, and the cervix so rigid as to require considerable time to secure dilatation enough to empty the uterus, better results will be obtained by a laparotomy.

In discussing eclampsia, the author states that when the pelvis is contracted and there is little or no chance of sepsis, abdominal Cæsarean section has given good results. In 245 cases of eclampsia treated by this method, the maternal mortality was 24 per cent. In 317 cases the foetal mortality was only 5.5 per cent.

Baldwin, J. F.: Two Unusual Cases of Ectopic Pregnancy; One a Triplet. *J. Am. M. Ass.*, 1913, lxi, 392. By Surg., Gynec. & Obst.

The first case was that of a patient thirty-seven years of age who had been married nineteen and a half years. She had two children; the youngest was sixteen years old. Her labors, except for one miscarriage thirteen years before at the sixth week, for which there was no assignable cause, were normal. Menstruation was normal and regular. The last period occurred two weeks before. An operation was performed for a proclivita which had been very annoying for the last two years. During the laparotomy a bilateral tubal pregnancy was discovered. On closer examination two fetuses were found in the left tube and one in the right. The embryos were of the same size and about as large as peas. The pathologist reported that all three were embryos of the same age. The second case was an ordinary tubal pregnancy. HENRY SCHMITZ.

LABOR AND ITS COMPLICATIONS

Gallant, A. E.: Prolonged Precipitate Parturition Due to Disengagement of the Disproportionate Head. *Med. Rec.*, 1913, lxxxiv, 337.

By Surg., Gynec. & Obst.

The author reports five cases of normal-sized pelvis in which there was dystocia due to a slight malposition of the child's head. With these, corrected labor ended rapidly. In two cases forceps were applied and, as the result of a too-heavy pull, the birth was precipitated and caused a severe tear of the perineum. It is possible by simple maneuvers to shorten the labor with less danger to both the mother and the child.

The manœuvres recommended are as follows: (1) External pressure on the buttocks at the fundus, which exaggerates the flexion of the trunk upon itself and of the chin upon the sternum; (2) external pressure on the occiput just above the symphysis, with the palm of the hand pressing the occiput down into the brim; (3) internal pressure on the forehead, with the fingers in the cervix, tilting the forehead upward during each pain; (4) the introduction of a single blade of the forceps to the occiput and gentle traction during a pain to facilitate flexion and engagement. This is best accomplished by a solid blade forceps, as the head will move more readily and the bulk of the forceps will help to fill up the roomy inlet and aid the head to engage more firmly and advance more surely; (5) guidance traction: high forceps — with loosely fitting blades, chiefly as guides and to prevent recession, care being taken not to drag too vigorously or suddenly or pay the penalty of a too-precipitate delivery and a tearing of the perineum of the mother which could have been avoided; (6) the judicious combination of two or more of these manipulations as the case may demand.

EDWARD L. CORNELL.

Bogdanowitsch, M.: Delivery in Total Paralysis of the Body (Entbindung bei vollständiger Lähmung des Rumpfes). *Zentralbl. f. Gynäk.*, 1913, xxxvii, 809.

By Zentralbl. f. d. ges. Gynäk. u. Geburtsh. s. d. Grenzgeb.

A xiii-para, thirty-seven years of age, had been suffering since the third month of pregnancy with a rapidly developing myelitis that began in the arms and spread to the trunk and legs. During the last weeks she suffered from urinary incontinence. On account of her hopeless condition Cæsarian section was contemplated, when labor contractions suddenly began. They were noticed by the attendant, but the patient experienced no pain. Within three hours the child was expelled by the breech, living but immature (44 cm., 2450 gm.). The placenta followed in fifteen minutes. There were no abdominal contractions as the abdominal muscles were paralyzed. The patient died three days later. Autopsy revealed a fibro-endothelioma of the spinal dura mater in the region of the atlas, with compression and softening of the spinal medulla.

This case is an excellent proof of the fact that the

motor functions of the uterus are independent of the spinal cord and are stimulated from peripheral nerve centers located in the uterus. TORGGLER.

PUERPERIUM AND ITS COMPLICATIONS

Werner: A Case of Puerperal Tetanus with Recovery (Über einen geheilten Fall von Tetanus puerperalis). *Monatschr. f. Geburtsh. u. Gynäk.*, 1913, xxxvii, 671.

By Zentralbl. f. d. ges. Gynäk. u. Geburtsh. s. d. Grenzgeb.

On November 25, 1913, the patient was delivered with forceps. A perineal tear was not sutured. Ten days after delivery she complained of difficulty in swallowing and slight trismus. The next day decided trismus set in, followed by rigidity of the neck and severe difficulty in swallowing. 100 units tetanus antitoxin (Höchst) were administered. On the following day the muscles of the face, arm, and lower limb were affected. Repeated convulsions occurred. The temperature rose to 40.6° C. Four more injections of 100 antitoxin units were given subcutaneously within the next few days. In addition, vaginal douches of a solution of powdered dried senna were employed. At the end of four weeks the patient was discharged cured.

ZINSSER.

Peterson, R.: Emptying the Uterus as a Method of Treatment of Puerperal Eclampsia. *Am. J. Obst.*, N. Y., 1913, lxviii, 201.

By Surg., Gynec. & Obst.

In this article Peterson has made a statistical study of the results obtained in a large number of cases of eclampsia collected from the literature, and draws the following conclusions:

1. Since the cause of eclampsia is still unknown, its treatment of necessity must be empirical.

2. Only through the analysis of large numbers of cases can the value of any particular treatment be correctly estimated.

3. In a large series of cases of eclampsia prompt delivery gave a maternal mortality of 15.9 per cent as compared with a maternal mortality of 28.9 per cent where the delivery was long delayed.

4. When the uterus is emptied immediately or very soon after the first convulsion the maternal mortality is still lower.

5. While before 1900 in a large group of cases the maternal mortality was 5 per cent in favor of conservative treatment and spontaneous labor, between 1900 and 1912, on account of better and more prompt obstetrical surgery, the figures were reversed and showed that the maternal mortality was 4 per cent lower after the radical treatment than after the conservative treatment of the complication.

6. Therefore, the treatment of antepartum eclampsia should consist of emptying the uterus as quickly as possible after the first convulsion.

7. The operative procedure that will empty the uterus most quickly and with minimum trauma and shock to the eclamptic mother and child is the one to be selected.

N. SPROAT HEANEY.

Zincke, E. G.: The Medical Versus the Surgical Treatment of Puerperal Eclampsia. *N. Y. St. J. Med.*, 1913, xiii, 422.

By Surg., Gynec. & Obst.

The author gives a very interesting review of the statistics of the medical and the surgical treatment of eclampsia. He claims that the maternal mortality from the surgical treatment is higher than that following the medical treatment. During the past ten years he has treated thirty cases of eclampsia, with a maternal mortality of 13.3 per cent, and a foetal mortality of 50 per cent. Two of the mothers were moribund when seen by him and a third died of shock and hæmorrhage following an *accouchement forcé* performed by the doctor in charge of the case. The fourth died soon after the eleventh convulsion and a comparatively easy vaginal hysterotomy performed without an anæsthetic.

Zincke advocates the following treatment: If the patient has, or has had, convulsive seizures, 25 drops (15 m. or 1 ccm.) of Norwood's tincture of veratrum viride should be given hypodermatically, and repeated every hour until the pulse is reduced to 60 per minute or less. If within an hour the pulse falls from 150 to 100 per minute, only from 10 to 15 drops should be injected in the succeeding dose. More than two or three injections are rarely necessary to bring the pulse down to 60. A copious enema of soap water serves to wash out the large intestine. The bladder should be emptied with a catheter, and the urine measured and examined. As soon as the patient is able to swallow, a saline cathartic should be administered. If this is ineffective, stronger cathartics may be given. Immediately afterward, the patient should be given a hot bath or hot pack, rubbed dry, and placed in a warm bed. The bath or pack should not be given oftener than twice in one day.

The only food should be milk or broth or both. Water or Fischer's solution may be freely administered. The latter may be given per rectum or, in urgent cases, intravenously. Chloral, per os or rectum, should be given if the patient is very restless. The author has discarded chloroform and morphia. Ether or gas-ether is the anæsthetic of choice.

C. H. DAVIS.

Polak, J.: On the Management of the Interior of the Uterus in Post-Abortal and Post-Partial Infection. *Tr. Internat. Cong. Med.*, Lond., 1913, Aug.

By Surg., Gynec. & Obst.

From a study of nearly 2000 cases the author draws the following conclusions: (1) The high morbidity in puerperal infection is due to meddlesome interference with the endometrium by surgical methods; (2) curettement of the placental site is a potent cause of thrombophlebitis of the pelvic veins; (3) the endometrium should never be curetted in streptococcal infection, whatever the stage of the pregnancy; (4) when the inside of the uterus is not disturbed by exploration, the infection is generally confined within the uterus and peritonitic and parametric complications are seldom noted.

The author analyzes one hundred and four cases treated in his wards by "conservative neglect" of the interior of the uterus. In no instance was the intra-uterine content disturbed. Only three deaths occurred, a mortality of less than three per cent.

Eight-four cases followed full-term delivery. Twenty were of the post-abortion type.

These women were placed in the Fowler position for postural drainage. Ergot and pituitrin were administered freely to secure uterine contraction and retraction. An ice bag was placed over the uterus and the physical resistance was sustained by forced feeding, strychnine, vaccines, and open-air treatment. Retained material was not removed.

Intra-uterine cultures were taken from eighty-nine patients. Fifteen had a closed cervix and in these no cultures were obtained. A hæmolytic streptococcus was recovered from the uterus thirty-four times; a non-hæmolytic, fifteen times; combined growths, fifteen times; staphylococci alone and in combination, fifteen times. Ten cultures were sterile.

Blood cultures were made in ninety-eight cases. In forty-six, streptococci of the longus or brevis types were recovered. Only two were hæmolytic.

In one of the three fatal cases no organism was developed from the blood; in another the streptococcus brevis was recovered; and in the third the bacteræmia was due to the staphylococcus aureus.

These facts are particularly impressive when it is remembered that a hæmolytic streptococcus was recovered in thirty-four uterine cultures and it would seem to confirm the author's conclusions regarding non-interference in puerperal infections.

Staude, C.: Peroneus Paresis Post-Partum (Über Peroneuslähmung postpartum). *Monatschr. f. Geburtsh. u. Gynäk.*, 1913, xxxvii, 611.

By Zentralbl. f. d. ges. Gynäk. u. Geburtsh. s. d. Grenzgeb.

CASE 1. The patient was a primipara, twenty-two years old, with a cephalic presentation. After a prolonged labor, she was delivered by forceps on account of an increase in her temperature and an acceleration in the sounds of the foetal heart-beat. The child weighed 4560 gms. A few hours after delivery cramp-like pains in the right leg set in, and the following day similar pains occurred in the left leg. There were noted also points that were painful to pressure. On the third day there was urinary incontinence and a diphtheretic membrane appeared in the vagina and vulva accompanied by fever. Next, a vesico-vaginal fistula developed to the size of a dollar. Six weeks after delivery the patient was allowed to get up. A weakness of the right leg was observed, due to peroneal paresis. An operation for the repair of the vesico-vaginal fistula was performed later and was complicated by the close proximity of the ureteral openings to the edges of the fistula. An improvement in the paresis was obtained after one year's treatment. The patient was able to walk fairly well with crutches and later

without them after the application of an elastic support for the foot. This paresis is explained by the prolonged pressure of the head in its slow passage through the pelvis. The fistula also was due to the same cause. In the literature four other cases of vesico-vaginal fistula complicated by peroneal paresis are recorded.

CASE 2. The patient was forty-two years old, a viii-para, with cephalic presentation and normal pelvis. During the second stage of labor she complained of pain on the outer side of the legs and feet. After cessation of the foetal heart tones, the anterior leg was brought down and extraction was rendered by delivery of the arms. Soon after delivery painful parasthæsiæ set in on the outer side of the legs and feet. Paresis gradually increased until the motor and sensory disturbance was complete in the peroneal region of the left leg and partial in the right. After a year, complete recovery had taken place.

The author gives a detailed account of the anatomical relations and the mechanism of nerve injury. An isolated peroneal paresis is rare, the lesions usually occurring in the ischial plexus, and the tibial as well as the obturator are involved. Paralysis of the glutei has rarely been observed, but is probably often overlooked. The latter produces a waddling gait and makes stair-climbing more difficult. The pains on the posterior surface of the thigh and outer surface of the leg are pathognomonic of the traumatic origin of the paresis, coming on during labor and usually preceding the paresis. Occasionally cramp-like contractions are observed in the limb during labor. Most of the labors require forceps delivery. Paresis is recognized only after a time, usually when the patient rises on the tenth day. It is frequently bilateral, but not equal in both sides. In the crural region, neuralgias and disturbances of sensation occur; never any paresis. The contracted pelvis plays an important rôle, the generally contracted type being more unfavorable than the flat rachitic. Injury to the nerves occurs much more often in cephalic presentations than in breech.

Staude lays considerable stress on the possibility of causing injury while forcibly hinging down a foot with the breech in the pelvis. Particular care is necessary in this manœuvre. The prognosis of puerperal peroneal paresis is not always favorable, dependent as it is upon the duration and force of the pressure exerted upon the nerve and upon the extent of the paresis. Duration is usually prolonged. Any pains or parasthæsiæ occurring in the peroneal region during labor must be considered danger signals.

EISENBACH.

MISCELLANEOUS

Wolff, B.: Foetal Hormones (Über fötale Hormone). Habilitationsschrift, Rostock, 1913.

By Zentralbl. f. d. ges. Gynäk. u. Geburtsh. s. d. Grenzgeb.

The chemical influence of the germinal cells during conception, the developmental importance of

the internal secretion of the foetus, the influence of the mother upon the child and of the child upon the mother during pregnancy, and the relation of the foetal hormones to tumor pathology are discussed in detail. Chemotropism of the germinal cells and chemical stimulation in their development is probably an hormone function. Just as a pregnancy reaction of the maternal organism is caused by the foetal structure, so a pregnancy reaction of the foetal organs occurs through the maternal structures.

It is not certain whether or not the germinal glands and the adrenals functionate during intra-uterine life. The thyroid gland and the hypophysis are active only under certain abnormal conditions. We have only a few positive proofs that the development of the foetus is influenced by its endocranial glands, but it may be dependant upon the hormones of the maternal organism, the uterus, ovaries, thyroid gland, etc. A number of the pregnancy changes in the mother, such as the changes in the mammary glands, the commencement of labor, the formation of protective ferments, the increase in the amount of antitrypsin in the blood, and intoxications are the result of the action of the foetal hormones. The pre-adolescence of women with tumors is due probably to the action of the hormones of blastomes with embryonal tissue upon the genital organs. It is known that pregnancy influences the growth of blastomes.

GRÄFENBERG.

Rougy, A. F.: The Use of Foetal Serum to Cause the Onset of Labor. *M. S. J.*, Calcutta, 1913, x, 109.
By Surg., Gynec. & Obst.

After discussing the work of Heide, the author takes up his own. Rougy followed the technique suggested by Heide in making the foetal serum. He used also practically the same general plan for his experiments. The foetal serum was tried on nineteen patients. In six cases, one or more injections produced labor pains which led to the expulsion of the child. All of these patients were at least ten to eighteen days before term. Two cases of inertia responded well to the serum shortly after the injection. The urine of one patient for whom the serum was used to bring on labor because of threatened eclampsia showed albumin and casts and was scant in amount for the twenty-four hours previous. In this case 55 ccm. of the serum was given in three days. The urine cleared after the first injection of 11 ccm. and the patient passed 80 ounces in the following 24 hours. Her general condition also improved. In seven cases the results were negative.

During the course of their investigations, Heide and Rougy found that severe contractions of the uterus did not cause pain unless the presenting part or the bag of waters compressed the cervix or other pelvic organs. Small doses of the serum seem to cause more of a reaction than larger doses. The most frequent symptoms noted by the author were chill, which lasted from two to thirty minutes, nausea, and vomiting.

EDWARD L. CORNELL.

Dietrich: Intrauterine Rupture of the Foetal Liver (Intrauterin entstandene Ruptur der kindlichen Leber). *Monatschr. f. Geburts. u. Gynäk.*, 1913, xxxvii, 868.

By Zentralbl. f. d. ges. Gynäk. u. Geburtsh. s. d. Grenzgeb.

The rupture occurred in the right lobe of the liver, near the lower margin, and consisted of deep stellate tears through the parenchyma. The child was delivered with forceps on account of the prolonged labor. The heart tones were normal before the extraction was begun, but were absent at birth. Autopsy showed that the child died of internal hæmorrhage into the peritoneal cavity through the hepatic rupture.

ZINSSER.

Adair, F. L.: Care of the Umbilical Stump. *J. Am. M. Ass.*, 1913, lxi, 537.

By Surg., Gynec. & Obst.

Adair discusses the etiology, pathology and clinical signs of omphalitis. He reports the bacteriological investigations carried on in sixty-five cases of new-born babies. In seventeen cases there was no bacterial growth. Non-pathogenic bacteria were found in thirty-three cases and pathogenic organisms in twelve cases. The staphylococcus was found in eight cases and the bacillus coli in four. In other words, pathogenic organisms were present on the cord and in its surroundings in nearly one fifth of the cases immediately after birth, although rigorous measures were taken to obtain aseptic conditions.

Essentials for the growth of organisms are: first, the presence of germs; second, the proper degree of temperature; third, suitable culture media and environs; and fourth, the presence of moisture. We can prevent the contamination of the parts and assist in the removal of the organisms by aseptic and antiseptic measures. The body-heat furnishes the proper temperature for bacterial growth but cannot be interfered with. The devitalized tissue of the cord forms an excellent medium. This we may remove by ligating or clamping the cord close to the skin margin. The presence of moisture may be controlled by keeping the small stump of cord under conditions which favor rapid drying.

These four conditions were fulfilled as follows: After the cessation of pulsation the cords were clamped near the skin margin and the surrounding skin and cord were cleansed with alcohol. The clamp was removed and in the groove that it had made a ligature was placed. In some cases the end of the cord and the surrounding skin were painted with 50 per cent tincture of iodine and in others they were left untreated. A sterile gauze dressing was then tied over the end of the cord. The babies were oiled for three days and then washed until the navel was healed. After this, tub baths were given. Each day the surrounding skin was washed with alcohol, and the dressing changed when necessary. By this comparatively simple method even serious umbilical infections were quite effectively combated.

HENRY SCHMITZ.

Krüger: The Care of the Nipple During Pregnancy (Warzenpflege in der Schwangerschaft). *Monatschr. f. Geburtsh. u. Gynäk.*, 1913, xxxvii, 867.
By Zentralbl. f. d. ges. Gynäk. u. Geburtsh. s. d. Grenzgeb.

Sixty per cent of the nipples that received no preliminary prophylaxis during pregnancy remained intact during the nursing period, whereas only fifty-four per cent of those that received attention did not become excoriated or fissured. Those cases that received preliminary prophylactic attention not infrequently developed a mastitis. Krüger considers manipulation about the mammaræ dangerous, for he has found it to be sufficient to bring on premature delivery.

ZINSSER.

Bailey, H. C.: The Clinical Significance of the Urine in Pregnancy. *Am. J. Obst.*, N. Y., lxviii, 263.
By Surg., Gynec. & Obst.

The author ends his exhaustive article with the following conclusions:

1. Liver degeneration in the toxæmias of pregnancy is accompanied by low nitrogen excretion. Changes have been reported also in the ratios of the nitrogen fractions.

2. Liver degeneration produced by a number of toxic substances is accompanied invariably by an increase in the total nitrogen excreted, but without important changes in the relationship of the various fractions to the total nitrogen.

3. Folin's work would attribute the amino-acid deamination chiefly to the tissues.

4. Pre-eclampsia and eclampsia may show no marked changes in the nitrogen partition.

5. It is probable that except for a lowering of the total nitrogen and changes in the various fractions due to the diet and the amount of absorption, the nitrogen partition in eclampsia will show no great differences in relationship.

N. SPROAT HEANEY.

Thompson, W. M.: The Influence of the Thyroid Glands on Pregnancy and Lactation. *Surg., Gynec. & Obst.*, 1913, xvii, 226.

By Surg., Gynec. & Obst.

In this paper are presented the reports of various laboratory workers together with a description of some experiments made by the author. It is shown that the sexual organs cause changes in the thyroid gland and the latter also influences the former. Thus in pregnancy there is a well-recognized hypertrophy of the thyroid that is normal. Goiter is discussed (1) as to the influence of childbearing on Graves' disease, (2) as to the influence of goiter on childbearing, and (3) as to the condition of the children of exophthalmic mothers. Clinical reports on the influence exerted by the thyroid upon lactation were cited. After reviewing the experiments of Marne and Lenhart, of Halsted of Johns Hopkins, and of Alguier and Thienveny, the writer closes with a description of experiments made on nine pregnant dogs. These experiments showed that the removal of one lobe of the thyroid had little or no influence on pregnant dogs or on their pups after birth. The

removal of one half, on the other hand, with the ligation and destruction of the remaining portion and of the parathyroids, was followed by tetanic seizures and death of the mother and pups. Further, it was shown that the total removal of the thyroid and parathyroids was followed by trembling and rigidity and that after birth of the puppies the milk was scanty and later both mother and progeny died.

Thompson's conclusions in brief are that the thyroid is a sexual gland if it originated from a glandular organ in connection with the sexual structures of the Palæostracean ancestors.

A lack of thyroid secretion influences sexual activity adversely. Sexual activity, whether it be physiological or pathological, causes a hyperactivity of the thyroids. Hyperthyroidism constitutes an index to the toxæmia of pregnancy, to counteract which the thyroids raise their antitoxic protective power. Clinical evidence supports the theory that the physiological hyperactivity of the thyroids is a valuable safeguard against the toxæmias of pregnancy.

CAREY CULBERTSON.

Polano: The Biological Diagnosis of Pregnancy (Zur biologischen Schwangerschaftsdiagnose). *Monatschr. f. Geburtsh. u. Gynäk.*, 1913, xxxvii, 857.

By Zentralbl. f. d. ges. Gynäk. u. Geburtsh. s. d. Grenzgeb.

Although Polano's results were correct as a rule, he occasionally obtained a positive reaction in non-pregnancy and a negative reaction in pregnancy. He fails to explain the cause of the error. Since all foetal organs as well as the serum and amniotic fluid come into communication with the maternal blood by way of dialysis, it is just as fair to assume that any or all of these may give positive reactions as well as the placental elements.

The serum of gestation contains more hæmolysins than does that of other blood. Boiled placenta and various foetal organs, especially the lung, show a greater hæmolytic activity toward the erythrocytes of pregnant than toward those of non-pregnant women.

ZINSSER.

Schwarz: The Serodiagnosis of Pregnancy.

J. Am. M. Ass., 1913, lxi, 484.

By Surg., Gynec. & Obst.

The author refers to the greater value of Abderhalden's biological test as compared with Rosenthal's test. He discusses the underlying principles, Abderhalden's work on cell metabolism, particularly as it regards protein metabolism, the mobilization of protective ferments in the blood, and the entrance of foreign material into the blood. He describes the dialyzation method for the detection of proteolytic ferments in the blood and gives his personal experience with it.

He reports the records of twenty-one pregnant and four puerperal cases in which the test invariably gave the violet-blue ninhydrin reaction, while the controls remained colorless. He investigated also eighteen non-pregnant cases, including several tubal

enlargements and four uterine fibroids. In addition, the tests were made on two males. In all of these, the dialysates of both tests and controls remained colorless.

HENRY SCHMITZ.

Maccabruni, F.: The Applicability of Abderhalden's Reaction for the Serum Diagnosis of Pregnancy (Über die Verwendbarkeit der Abderhaldensche Reaktion bei der Serumdiagnose der Schwangerschaft). *München. med. Wchnschr.*, 1913, ix, 1259.

By Zentralbl. f. d. ges. Gynäk. u. Geburtsh. s. d. Grenzgeb.

The author investigated Abderhalden's serum reaction in one hundred cases of pregnancy. He employed the polarimetric and the dialytic methods and was able to confirm Abderhalden's results. The reaction occurs early in pregnancy and persists fourteen days after labor and after abortion. Of the results obtained in eighty-five, only one was negative and only two were doubtful. Only once was a positive reaction obtained in the absence of pregnancy.

The author further investigated the dialysis method with foetal serum. Contrary to the results of Decios, he obtained a positive reaction in several cases. The examination of the urine of pregnant women did not reveal anything definite. The liquor amnii may at times give a positive reaction. The spinal fluid in two cases of eclampsia gave a negative reaction. In a few cases of albuminuria, severe vomiting, and eclampsia, the reaction was neither very weak nor very positive. The question whether the reaction involves only the placenta or also the foetus depends upon whether the foetus produces protective ferments in the mother. The investigations so far are too few to warrant conclusions.

BENTHIN.

Herz, E.: A Case of Rupture of the Uterus Following the Administration of Pituitrin (Ein Fall von Uterusruptur nach Pituitrin). *Zentralbl. f. Gynäk.*, 1913, xxxvii, 720.

By Zentralbl. f. d. ges. Gynäk. u. Geburtsh. s. d. Grenzgeb.

Following the injection of 1 cc. of pituitrin in a case of labor with weak pains and three to four fingers cervical dilatation, powerful contractions set in which within twenty minutes assumed a tetanic character. About one hour after the injection there occurred a severe tetanic contraction with sudden collapse, and the spontaneous delivery of a deeply asphyxiated child. The expulsion of the placenta was followed by hæmorrhage due to a transverse tear of the lower uterine segment through which the child and placenta had been delivered. The tear remained subserous. The portio was entirely free in front and connected with the uterus only posteriorly. Tamponade was performed and pantopon administered. Three weeks later the patient was discharged.

Herz believes that it is a mistake to administer pituitrin in the first stage of labor. In the case reported, however, there may have been some unusual condition. In forty-seven cases pituitrin

frequently caused nausea, dizziness, vomiting and tinnitus aureum, especially in weak, anæmic women. The influence upon the child also was bad. The unfavorable results reported from other sources include uterine atony, post-partum asphyxia of the child, collapse, tinnitus aureum, nausea and dizziness, contraction of the cervix, tetanus uteri, and premature separation of the placenta. PONTICK.

Jaeger, A. S.: Gonorrhœa in Relation to Pregnancy and the Puerperal Period. *J. Indiana St. M. Ass.*, 1913, vi, 353.

By Surg., Gynec. & Obst.

The author has classified gonorrhœal infection in the pregnant woman as follows:

Acute gonorrhœa. (1) Infection present at the time of uterine implantation. (2) Infection occurring during the first four months of pregnancy. (3) Infection occurring between the fourth and the seventh months. (4) Infection occurring between the seventh month and delivery. (5) Infection occurring after delivery, during the lying-in period. This is very rare.

Chronic gonorrhœa. Active form: (1) Simple chronic gonorrhœa in which the disease runs an unchanged course during the entire pregnancy and puerperium. (2) Acute exacerbation of a chronic gonorrhœa, occurring during any period of the pregnancy or the lying-in period. Latent form: (1) Gonorrhœa demonstrable, but subjective and objective symptoms negative. (2) Gonococci undemonstrable, but previous history, and subjective and objective symptoms suggestive.

From observation the author has learned that the treatment should differ according to the period of pregnancy on account of the danger of interrupting the pregnancy. There is always a chance of abortion during the first four months and of premature birth during the last two months, in the presence of a specific acute or chronic endometritis.

Conservatism is the keynote in treatment. Heat and instrumentation is contra-indicated. If the infection is unusually severe, active treatment is best tolerated between the fourth and seventh months.

The author uses forceps in these infected cases only as a last extremity, and believes that perineal tears should as a rule be cleansed and repaired. If the vulvo-vaginal gland has formed an abscess, it is usually drained and packed before delivery.

His conclusions are as follows: (1) Chronic gonorrhœa, or an acute involvement of the endometrium that is present at the time of uterine implantation, is much more serious as regards the successful termination of pregnancy than primary acute disease that occurs after gestation. (2) Individualism and conservatism in the treatment show the smallest percentage of serious complications and the best ultimate results. (3) Post-partum infections are best treated by absolute rest and good drainage; operative procedure should be undertaken only after careful consideration of specific indications.

EUGENE CARY.

GENITO-URINARY SURGERY

KIDNEY AND URETER

Cohnheim, Otto: The Physiology of Kidney Secretion (Zur Physiologie der Nierensekretion). *Sitzungsb. d. Heidelb. Akad. d. Wissensch. Math.-naturw. Cl.*, 1913, vi, 1.

By Zentralbl. f. d. ges. Chir. u. i. Grenzgeb.

From an examination of mammalian kidneys taken fresh from the body, freed from blood, and macerated, the author attempted to determine whether a combination takes place between sugar and salt and the solid constituents of the kidney, and whether there is a definite limit beyond which this combination does not take place, such as Magnus had already demonstrated for the secretion of sodium chloride. From numerous experiments he came to the conclusion that such a combination actually does take place and that a sharp boundary for salt can be determined at 0.6 per cent. If the kidneys are put into salt solution of a lower concentration no combination takes place. Considerable amounts are combined from solutions of higher concentration. For grape sugar the limit is 0.3 per cent. The combination was unstable and easily dissolved by heating.

These processes cannot be explained by osmosis, because then there would be no clear explanation for the sudden variation in the limits, but Cohnheim believes that the kidney fixes the material from the solution by chemical combination and absorption.

LOBENHOFFER.

Grigorjew, S. P.: The Radiographic Examination of the Kidneys (Die Röntgenuntersuchung der Nieren). *Verhandl. d. XII Kong. russ. Chir.*, 1913, xii, 173. By Zentralbl. f. d. ges. Chir. u. i. Grenzgeb.

The author considers important not only radiography of the kidneys but also the fluoroscopical examination. The absence of respiratory movement of the kidney speaks for perinephritic adhesions. The higher grades of wandering kidneys can also be demonstrated in this manner. If during repeated illumination the contour of the kidney or of the muscles is not visible, a paranephritis must be thought of. Furthermore all stones larger than a millet seed can be seen on the illumination diaphragm. If during a deep respiration the stone and the lower pole of the kidney do not change their relation to each other, the shadow is of intrarenal origin. If a change does occur in the relation, the shadow is of extrarenal origin. The ureters possess a respiratory movability of 1 to 2 cm. To obtain good results in radiography, the time of exposure must not be more than one sixth to one tenth of a second and two exposures should be taken, one during inspiration and one during expiration.

The author has collected eighty-two cases of nephrolithiasis. In eleven cases the stones were passed. In forty-four cases the stones were removed by operation. In two cases the stones were bilateral. In all instances the radiographic diagnosis was correct. Only in one case in which the stone was localized in the cervix of the uterus was it found above it in the infundibulum. In six cases the diagnosed stones were not found on operation. In three of these, however, a spontaneous expulsion of the stone was observed, and in the other three the stones remained in the kidneys and gradually increased in size. According to the author, the determination of the size of the stones by means of false projection is impossible.

HESSE.

Kawasoye, M.: Anatomical Changes in the Kidney After Ligation of the Ureter (Ein weiterer Beitrag zur anatomischen Veränderung der Nieren nach dem künstlichen Ureterverschluss). *Ztschr. f. gynäk. Urol.*, 1913, iv, 107.

By Zentralbl. f. d. ges. Gynäk. u. Geburtsh. s. d. Grenzgeb.

The author reports the anatomical changes in a case of hydronephrosis, in which the post-mortem examination of the animal was made 309 days after the ligation of the ureter. Corbett found changes caused by nephrotoxic processes on the non-ligated side. Kawasoye, however, did not find such changes and emphatically denies that any change is caused on the non-operated side by the ligation of the ureter. The alterations found by Corbett he believes must have been caused by septic infection resulting from the operation. On the ligated side there was a marked atrophy of the parenchyma, while the same amount of fluid was present in the pelvis of the kidney after 309 days as after 70 days. The glomeruli were the most resistant part of the kidney parenchyma.

A. HIRSCHBERG.

Hadden, D.: Bacteriology of the Urine in Relation to Movable Kidney. *Calif. St. J. Med.*, 1913, xi, 326. By Surg., Gynec. & Obst.

Hadden records eight cases to show that a displaced kidney causes stasis of the urine, and, through the alteration of the chemical contents, furnishes a medium on which certain germs, entering from the neighboring organs or from the blood stream, can grow.

He believes that left-sided ptosis is more frequent than is generally supposed, and that in many cases it is not associated with right-sided ptosis. The reason he gives for the fact that many cases of displaced kidneys are without symptoms is that the individual is in good physical condition and as long

as such is the case, the peristaltic action of the kidney, pelvis, and ureter is maintained and stasis of urine is prevented.

In the treatment, results cannot be expected from vaccines until the ptosis is corrected and drainage is effected. He claims that we have swung from kidney fixation because we have tried to cure movable kidneys, associated with enteroptosis, without supporting the other organs. He inclines to the method of Longyear with the fixation of the capsule as it corrects any colon sag that may be present.

His conclusions are as follows: (1) Normal urine is sterile; (2) the greater number of chronic infections of the urinary tract are associated with a bladder or kidney ptosis or both; (3) "unilateral nephritis" is a condition of infection having a kidney sag as its origin; (4) many movable kidneys are without pathological significance because the muscle tone is unimpaired; (5) when the muscle tone becomes impaired we have urine stasis and infection; (6) every movable kidney is a latent source of trouble; (7) in the bacteriological examination of the urine we have a means of diagnosing the pathological "floating kidney"; (7) the degree of symptomatology depends on the kind of infection and the sensibility of the patient; and (8) if we are able to diagnose positively a pathological "floating kidney," we will consider more seriously the operative treatment and the type of operation, for at best the kidney support is only temporary and it is often impossible to apply it properly. LOUIS GROSS.

Vincent, W. G.: An Unusual Case of Renal Hæmaturia; Unilateral Chronic Hæmorrhagic Nephritis; Decapsulation; Apparent Cure; Recurrence; Bilateral Involvement; Decapsulation of Both Kidneys Six Years Later. *Med. Rec.*, 1913, lxxxiv, 106. By Surg., Gynec. & Obst.

The author reports a case in which the right kidney was found to be the source of severe and long-continued hæmorrhages. Decapsulation on that side was followed by a rapid disappearance of the symptoms and an apparent cure for five years. During the sixth year, the symptoms recurred and catheterization of the ureters showed that the hæmorrhage was bilateral. Decapsulation of both sides was then performed. Patient's condition improved, but symptoms were not fully relieved.

Examination of sections from the kidneys showed chronic hæmorrhagic nephritis. The right kidney gave evidence of "replacement fibrosis" following the first decapsulation. H. L. SANFORD.

Pena, M.: On the Significance of Renal Hæmaturia Immediately Following Nephrectomy for Tuberculosis (De la valeur de l'hématurie rénale immédiatement consécutive à une néphrectomie pour tuberculose). *J. d'uro.*, 1913, iv, 43.

By Journal de Chirurgie.

Post-operative hæmaturia from the remaining kidney after nephrectomy for tuberculosis is but

little recognized, though it occurs often. It is a hæmorrhage of pure blood, and begins usually from one to five days after the operation. It may not appear until the fifteenth day. In two thirds of the cases the hæmorrhage is severe. It is intermittent and lasts usually a short time, usually for one or two days. In some cases, however, it may continue for eight, ten, or thirty days. It ceases gradually. In short, the hæmaturia following nephrectomy for tuberculosis may be characterized as an idiopathic hæmaturia, not very intense, intermittent, and of short duration.

The pathogenesis is doubtful. The hæmaturia may be due to tuberculosis of the remaining kidney, to a benign colon bacillus infection of the remaining kidney, or to the compensatory hyperæmia of the remaining kidney. The prognosis is bad in the first case, and good in the others, but it is difficult to state at the beginning to which class it belongs.

J. TANTON.

Iljin, A. J.: The Question of Ascending Infection of the Kidney and the Prevention of the Same by Implantation of the Ureters into the Bowel (Zur Frage der aufsteigenden Niereninfektion und die Bekämpfung derselben bei der Ureteren-transplantation in den Darm). *Dissertation*, St. Petersburg, 1913.

By Zentralbl. f. d. ges. Chir. u. i. Grenzgeb.

From a large amount of data in the literature and from his own experience, the author comes to the conclusion that transplanting the ureters into the bowel is better than transplanting them into the skin, while the danger of kidney infection is less. The cases in which ureteral implantation may be used may be divided into four groups as follows: (1) Diseases in which in addition to the ureteral implantation, the bladder must be extirpated, as in extrophy of the bladder, carcinoma of the bladder, carcinoma of neighboring organs in which the bladder also is involved, benign but frequently recurring tumors, and tuberculosis of the bladder with marked anatomical changes; (2) diseases in which ureteral implantation is performed without extirpation of the bladder, as in tuberculosis which is not accompanied by serious changes of the bladder, but which does not respond to the usual methods of treatment, and in high epispadias with insufficiency of the sphincter of the bladder; (3) diseases in which the ureteral implantation is indicated as a palliative operation, as in inoperable carcinomas, bladder tuberculosis with tuberculous kidneys, and generalized tuberculosis.

The infection of the kidney following transplantation of the ureters is primarily urogenous. It is favored immediately after the operation by the stasis of the urine in the ureters due in part to the reflex paralysis of the ureters and in part to constriction of the anastomotic ring and the bowel musculature, and to inflammatory infiltrations. Later on, after the ureters have recovered, it may be due to the lymphatic stream. The principal organism is the bacillus coli communis.

The author discusses eleven personal cases. In all, the operation was performed according to the method of Mirotworzeff of the Oppel clinic. Seven times it was for extrophy of the bladder, three times for high epispadias with aplasia of the bladder sphincter, and once for high grade tuberculosis. Ten of the operations were radical and one palliative. The latter cured the patient of his continual desire to urinate and of his pain. Seven patients were discharged cured and four died, one of peritonitis, one of shock, one of generalized tuberculosis, and one, two and one half years after the operation, as a result of sepsis following a plastic operation on the bowel. Excluding the last two cases, there remains an operative mortality of 18 per cent, both of the deaths occurring in children, aged one year and nine months, and one year and two months respectively. The author agrees with Maydl that the operation should not be performed on children. During the post-operative period, lactobacilline was given and was well tolerated by the patients. In three cases in which there was an inflammatory condition of the bowel, the result obtained was good, and in others the discharge of mucus ceased. In one case no effect was obtained. From the urine examinations following the operation it was found that there was a retention of the chlorides of the urine, attributable to a pyelitis acuta. A decrease in the excretion of nitrogen also occurred, due probably to the polyuria from which most of the patients were suffering. Uræmic symptoms were not observed. In four cases of post-operative pyelitis the vaccine therapy of Wright was employed, autogenous colon vaccine made from urine organisms being injected in small doses which were gradually increased. The maximum dose was 150 million bacteria. In two of the cases, cure resulted following six injections. One case improved, and in another the injections had to be discontinued on account of the continuous high temperature. In one case the vaccine was used as a prophylactic before the operation.

After the author had employed the vaccine on eighteen dogs experimentally, he came to the conclusion that it cannot prevent the ascending infection of the pelvis and kidney. The disease was more severe and set in earlier in those cases in which a stenosis of the anastomotic ring and a stasis of urine occurred. In cases in which the flow of the urine was free, the kidneys were found to be healthy even a long time after the operation. The monograph is accompanied by an extensive bibliography, three plates, and numerous drawings. O. VON SCHILLIN.

Condon, A. P.: Unilateral Septic Infection of the Kidneys. *N. Y. M. J.*, 1913, xcvi, 279.

By Surg., Gynec. & Obst.

Unilateral septic infection of the kidney is caused by the successful invasion into the kidney of micro-organisms and their products which usually produce numerous miliary abscesses and often violent general symptoms.

The writer reports two interesting cases, one a severe type demanding immediate operation and the other a milder form.

The origin of these infections is usually hæmatogenous. Predisposing causes are: (1) Pregnancy; (2) passive congestion of the kidney; (3) infections such as erysipelas, endocarditis, scarlet fever, etc. The exciting cause is a pathogenic micro-organism, usually the colon bacillus.

The symptoms appear suddenly, and consist of severe and continuous pain over the affected organ, marked tenderness, hyperæsthesia of the skin over the kidney, and rigidity of the lumbar muscles. There is usually vomiting, fever, rapid pulse, prostration and a high leucocytosis. The urinary findings vary; pathological findings may be absent; usually, however, there is pus, albumin, and microscopic blood.

The indications for operation are: (1) Intensity and progressiveness of symptoms; (2) high temperature; (3) leucocyte count above eighty, etc. Such cases should be operated upon at once. A few will undergo resolution and others will recover if properly drained. A radical operation, however, is usually indicated.

The writer mentions Brewer and Cobb as having done extensive work in the study of septic conditions of the kidney.

H. A. MOORE.

Papin: The Localization of Renal Tuberculosis by Radiography (Localisation de la tuberculose rénale par la radiographie). *Arch. urol. clin. de Necker*, 1913, i, 197. By Journal de Chirurgie.

Radiography sometimes shows at the site of a tubercular kidney, spots corresponding either to hollow spaces or calcareous or caseous areas. These spots may be of prime importance in deciding the question as to whether nephrectomy should be performed in the case of a subject who shows urinary tuberculosis but in whom the bladder cannot be explored on account of its sensitiveness. In such a case we can demonstrate that one of the kidneys is sound if Ambard's coefficient, the relation of the urea in the blood to that in the urine, is normal, but we still have to determine which is the normal kidney. If we have no other localized symptoms, radiography may settle the question. The author cites two cases in which, when the kidneys showed a spot in the radiographic picture, bladder exploration was impossible, and the Ambard coefficient was normal or subnormal, nephrectomy was performed successfully. MAURICE CHEVASSU.

Thomson, J.: The Infection of the Urinary Tract in Children by the Colon Bacillus. *Lancet*, Lond., 1913, clxxxv, 467.

By Surg., Gynec. & Obst.

On the basis of seventy-one personally observed cases of this kind, the author concludes that different types of colon infections are predisposing factors. He differentiates between the normal colon bacillus and the virulent organism. Any cause that retards

the downward passage of the urine is influential in inviting a colon bacillus infection. This infection is twice as common in children under two years as in those that are older. Seventy-nine per cent of the cases that he observed occurred in girls. During the first six months of life, however, a much greater number of boys than girls were affected. An analysis of cases of two hundred and twenty-four babies two years of age, reported by thirteen authors, shows that more boys were affected during the first six months than at any later age. The author claims, further, that the attacks in male patients are apt to be more severe than those in females and there is usually in the former a much larger proportion of cases of fatal pyelonephritis. He does not attempt to explain the reason for this.

The differential diagnosis of acute coli-pyelitis depends, first, on the presence of pus and colon bacilli in the urine along with the typical general symptoms which the author describes somewhat in detail, and, second, the absence of any sign of organic disease outside of the urinary tract that might account for the condition.

As treatment Thomson recommends, first, measures to cause the urine to become alkaline; second, the administration of antiseptics; and third, the use of serums and vaccines.

Glynn, E., and Hewetson, J. T.: Adrenal Hypernephroma in the Adult Female Associated with Male Secondary Characters. *J. Pathol. & Bacteriol.*, 1913, xviii, No. 1.

By Surg., Gynec. & Obst.

The case is reported of a woman forty-four years of age who for sixteen years has been showing a gradually increasing number of sex abnormalities. Her voice was coarse, her face and trunk hairy, and her breasts were of the male type. At the operation which was followed by her death, a twelve-pound tumor was removed from the region of the left kidney. Microscopical examination showed it to be of adrenal origin.

The authors compare the structure of this tumor with that of four similar tumors which they have had the opportunity to study. They classify all five as "adrenal hypernephromata" in contradistinction to "renal hypernephromata," and maintain that tumors of this type are not malignant.

Seven cases of adrenal hypernephroma in young adult females, associated with changes in sex character, are tabulated. Our knowledge of the relationship of such tumors to abnormal sex characters is summarized by the authors as follows:

1. In children, hirsuties and other abnormalities are almost invariably present.
2. In adult females before the menopause, sexual abnormalities are frequently present.
3. In females after the menopause definite sexual aberrations are not recorded.
4. In adult males such changes are not noted.
5. There is no evidence that hypernephroma in the kidney, which has a totally different histological

structure from that in the adrenal, is ever associated with abnormal sex character. G. G. SMITH.

Jachés, L.: Pyelography. *Tr. Am. Röntg. Ray Soc.*, Boston, 1913, Oct. By Surg., Gynec. & Obst.

There were two important epochs in the development of the röntgen diagnosis of diseases of the urinary system. The first began in 1898, when Leonard published his papers establishing the rules for the determination of the sufficiency of the röntgenogram in order to make a positive or negative diagnosis regarding urinary calculus; the second in 1905, when pyelography and cystography were introduced by Voelcker and von Lichtenberg.

Pyelography enables us to diagnose hydro-nephrosis, renal tuberculosis or tumor, the position of the kidney, and congenital anomalies, such as fused kidney, kinks, constriction or dilatation of the ureter, and diverticula.

Cystography shows the size and shape of the bladder, anomalies and pathological conditions, such as diverticula and trabeculations, and changes caused by hypertrophy of the prostate.

The dangers of pyelography are collapse due to over-distention of the renal pelvis, irritation of the kidney followed by high fever, and deposits of the silver salt in the kidney substance. Caution is advised where only one kidney is present or when the other kidney does not functionate properly. The dangers of pyelography were further illustrated in a case in which a diverticulum in the ureter could be demonstrated only by argyrol, and in which several months later the shadow of the diverticulum could be seen very distinctly. The patient refused operation, so that the question as to whether the silver salt had remained in the diverticulum all this time could not be solved.

Lantern slides were shown illustrating the various conditions named above.

In the discussion STOVER of Denver suggested that the shadow remaining in the region of the diverticulum may have been due to a calculus that was not shown before because of its chemical composition but which became visible as the result of absorbing some of the argyrol.

Legueu and Papin: The Technique and Accidents of Pyelography (Technique et accidents de la pyélographie). *Arch. urol. clin. de Necker*, 1913, i, 12.

By Journal de Chirurgie.

By pyelography the authors mean the injecting of a substance that is opaque to X-rays into the ureters and pelves of the kidneys before taking a picture. Legueu and Papin have worked on this for two years and report the method used, the results obtained, and the accidents met with.

They found that the best method is to inject ten per cent collargol through a ureteral catheter passed up to the pelvis of the kidney. Also that it is better to introduce the collargol by gravity from a curette 80 cm. above the patient than to force it in with a syringe. When the pelvis is full

there is pain in the back and no more fluid should be used. The fluid must remain in until after the radiograph is taken. It is not necessary to wash it out.

By pyelography it is possible to demonstrate the exact location of the pelvis of the kidney, its relations to the ureter, and the presence of curved ureters, double ureters, hydronephrosis, tumors, stones (the latter especially if oxygen is used instead of collargol), tumors, tuberculous cavities, etc. In short, it is invaluable in the diagnosis of renal troubles and of lesions of the pelvis or ureters.

Pyelography may be accompanied by pain which lasts for several hours or even days afterward and which may resemble kidney colic. Small doses of morphine and hot compresses in the lumbar region, however, give relief. There is also sometimes a slight fever (38° to 39° C.) lasting for two or three days. Sometimes there is infiltration of the renal parenchyma, which may be seen by radiography and upon operating. This in one case caused death (Rössle). Legueu and Papin believe it to be due to the use of too great pressure in administering the collargol, for they have had no such trouble since they stopped using a syringe.

MAURICE CHEVASSU.

Von Illyés, G.: Experiences in Renal Surgery (Erfahrungen auf dem Gebiete der Nierenchirurgie). Budapest: Franklin, 1913.
By Zentralbl. f. d. ges. Chir. u. i. Grenzgeb.

In this monograph the author describes three hundred and forty-nine kidney operations that he performed during a period of eight years. The diagnostic and operative methods are minutely described, and the work is full of practical hints. The operative results are noteworthy. There were twenty-four cases of tumor with 16.6 per cent mortality; seventy-five cases of kidney and ureteral calculi, with a mortality of 60.6 per cent; twenty cases of hydronephrosis with a mortality of 0 per cent; twenty-five cases of pyonephrosis with a mortality of 20 per cent; sixteen cases of pyelonephrosis, with a mortality of 20 per cent; sixteen cases of pyelonephritis and kidney abscess, with a mortality of 0 per cent; and 141 cases of tuberculosis, with a mortality of 4.2 per cent. The end-results of the last, however, showed a mortality of 17.4 per cent. There were three cases of anuria, one of syphilis of the kidney, one of cystic degeneration. Of floating kidney there were fifteen cases, with no mortality. Nine exploratory operations had no mortality. Perinephritis fibrosa, five cases, and perinephritic abscess, three cases, had no mortality. The average mortality was 17.2 per cent.

VON LOBMAYER.

Gibbon, J. H.: The Technique of Nephro-, Pyelo-, and Ureterolithotomy. *Ann. Surg., Phila.*, 1913, lviii, 232.
By Surg., Gynec. & Obst.

Nephrotomy is the operation of choice only for large, branching, phosphatic stones, for small stones

lodged high up in the calices, and for cases in which the kidney is badly infected; in other cases pyelotomy is preferred. For the removal of multiple, widely distributed stones, the author prefers making several incisions directly over the calculi instead of splitting the entire kidney.

Pyelotomy is favored for the removal of most renal calculi. The fat overlying the pelvis and the pelvis itself should be incised longitudinally in different planes, and at the conclusion of the operation they should be sutured separately. There is little danger of urinary leakage when this plan is followed.

If stones in the lower part of the ureter are not easily located by the extraperitoneal route, the author at once resorts to the transperitoneal method of approach, using this, however, only for the purpose of locating the stones and pushing them into a position where they will be accessible through the extraperitoneal wound. This method promotes speed in operating, gives an opportunity to thoroughly explore both ureters, and has been found to be safe.

S. W. MOORHEAD.

Bromberg, R.: A Contribution to the Functional Diagnosis of the Kidney (Beitrag zur funktionellen Nierendiagnostik). *Beitr. z. klin. Chir.*, 1913, lxxv, 411.
By Zentralbl. f. d. ges. Chir. u. i. Grenzgeb.

Löwenhardt was the first to call attention to the value of determining the electrical conductivity for the functional diagnosis of the kidney. The method has rendered very good results as has been stated several times by Kümmell. Bromberg employs a slightly modified apparatus for measuring the electrical conductivity, and emphasizes particularly the value of comparing the electrical conductivity of the blood serum and of the urine of both kidneys. According to the author, this hæmorenal index is the only method by which the functional activity of the kidneys can be determined absolutely.

OEHLCKER.

Scott, G. D.: Hydronephrosis Produced by Experimental Ureteral Obstruction. *J. Indiana St. M. Ass.*, 1913, vi, 339.
By Surg., Gynec. & Obst.

Scott describes and draws conclusions from original experiments performed upon some fifty dogs. He found that hydronephrosis can be obtained from both complete and partial ureteral obstruction, the degree depending upon the duration of the obstruction. Complete obstruction was the more rapid in development.

The pathological changes were due to the back pressure of the retained fluid on the kidney epithelium and to the poor nutrition resulting from pressure on the renal vessels. The tubules were dilated; the epithelium was flattened and its cytoplasm became granular; the interstitial tissue was increased; and in late stages the vessels were sclerotic. In hydronephrosis even of the latest stage, the kidney epithelium was capable of regeneration.

BLADDER, URETHRA, AND PENIS

Legueu: Foreign Bodies in the Bladder and Their Treatment (Fremdkörper in der Blase und ihre Behandlung). *Allg. wien. med. Ztg.*, 1913, lviii, 176. By Zentralbl. f. d. ges. Chir. u. i. Grenzgeb.

The author reports the removal of a hairpin from the bladder of a young girl, and discusses the symptoms of foreign bodies, especially hairpins, in the bladder, pointing out the most appropriate treatment. For diagnosis the X-ray should not be depended upon entirely, but each case should, if possible, be cystoscoped. Extraction without the aid of the cystoscope, by means of a hook or similar instrument, usually fails, since the pin generally lies transversely and it is quite difficult to hook into its closed end.

Even with the aid of the cystoscope the author found it so difficult to remove the pin that he advises suprapubic incision. In the female if the foreign bodies are smaller and not encapsulated, the author makes an incision about 2.5 cm. in length beneath the symphysis and between the clitoris and urethra. This incision extends to the bladder, and the urethra is opened along its whole length without injuring the collum vesicæ. After the foreign body has been extracted the incision is sutured and it heals without the formation of a fistula. DENCKS.

Bugbee, H. G.: The Relief of Vesical Obstruction in Selected Cases. *N. Y. St. J. Med.*, 1913, xiii, 410. By Surg., Gynec. & Obst.

The author suggests the use of the high frequency current applied in the same manner as proposed by Beer in the destruction of vesical papillomas, to burn away obstruction at the bladder neck, and for cases of enlarged prostates and median bars. He reports fourteen cases of various kinds of obstruction in which the obstructing part was burned away or through, and in which he reduced the residual urine. The article has numerous illustrations which show the marvelous manner in which the obstructing portion disappears. B. S. BARRINGER.

Legueu: The Electro-Coagulation of Tumors of the Bladder (De l'électro-coagulation des tumeurs de la vessie). *Arch. urol. clin. de Necker*, 1913, i, 131. By Journal de Chirurgie.

Excision is the treatment of choice for tumors of the bladder of any considerable size, but for extremely small tumors or for small recurrent nodes the endovesical treatment is distinctly preferable.

Legueu has studied the action of high frequency currents on tumors of the bladder, using both Beer's method, which has a coagulating and diathermal effect, and the method of d'Heitz-Boyer and Cottenot, which has a disintegrating action. The two methods seemed to him to be about the same in their action as well as in their results. He prefers Beer's method, however, as it does not require a special cystoscope. He has had an electrode made the size of a ureteral sound which can be

passed through any cystoscope. It ends in a copper button through which the diathermal current is passed by means of a d'Arsonval bipolar apparatus.

The action of the diathermal current is described in detail. The author studied it histologically on a tumor treated by electro-coagulation immediately before it was excised.

He gives his patients a treatment of five minutes duration every two weeks, with a current varying in intensity from 250 to 350 milliamperes. It is useless to give the treatments closer together, for the elimination of the coagulated particles takes a considerable length of time. He used the method five times for palliative treatment and noted that it caused a diminution or cessation of hæmorrhage. Five times he used it for curative purposes: two tumors were cured after five treatments, one after six treatments, one almost cured after six treatments, and one was very much decreased in size after the sixth treatment.

The application of high frequency currents in the treatment of tumors of the bladder constitutes a great advance in endoscopic technique.

MAURICE CHEVASSU.

François, J.: Transformation of a Cystic Cystitis into a Glandular Cystitis (Sur la transformation de la cystite kystique en cystite glandulaire). *J. d'urol.*, 1913, iv, 207.

By Journal de Chirurgie.

François made an histological study on a surgical specimen of the transition from a cystic cystitis to a glandular cystitis.

The patient, a woman of 33, entered the hospital for a very intense cystitis with frequent and abundant hæmaturia. The urine was purulent and the capacity of the bladder was reduced to 60 ccm. The kidneys were normal.

The cystoscope showed the fundus red and tomentous in places. Clinically there was an intense, non-bacillary cystitis without involvement of the kidneys.

Operation showed the mucous membrane of the whole trigonum surrounding the openings of the two ureters, red, ulcerated, irregular and tomentous. The right urinary meatus was swollen, red, and somewhat patent. All of the diseased mucous membrane was destroyed by thermocautery. A month later the patient had recovered, and the capacity of her bladder had reached 200 gms.

Histological examination: At the edge of the tomentous area, full and sphenoidal von Brunn epithelial nests were found in the submucous layer; as the center of the tumor was approached these nests showed a hollow central cavity and the cells bordering the cavity were of the secretory type. In the center of the tumor the mucous membrane had almost entirely disappeared; there were some cystic formations in the submucosa, but the most characteristic appearance was given by mucous glands bordered with a single row of cylindrical cells, resembling the mucous glands of the intestine.

These formations are characteristic of glandular cystitis. The transformation of the polyhedral cells of the vesical epithelium into secretory cells which ultimately take on the characteristics of mucous cells could be observed.

Along with this process, mucous cells appeared and multiplied in the covering of the epithelial crypts; that is, a certain area of normal stratified vesical epithelium was transformed into a layer of cylindrical cells which were nothing more than mucous cells. The inflammatory lesions of the submucosa were greatest in the zone of glandular cystitis and less intense in the zone of cystic cystitis.

Calculi, neoplasms, chronic cystitis—in short, any chronic irritation, as Chiari has shown experimentally—may give rise in the lower part of the vesical epithelium to von Brunn's epithelial nests and the cysts which result from them.

The glandular formations may have either one of two origins: they may be due to an embryonic inclusion of germinal cells from the intestinal tract, as is the case in pure glandular cystitis without cystic cystitis at the periphery, or to the transition of vesical epithelium into mucous cells passing through the stage of cystic cystitis.

J. TANTON.

GENITAL ORGANS

Eckels, L. S.: Epididymotomy, the Radical Operative Treatment of Epididymitis. *J. Am. M. Ass.*, 1913, lxi, 470. By Surg., Gynec. & Obst.

Eckels is firmly convinced of the desirability of the operative treatment in every case of acute epididymitis. His opinion is based on the observation of one hundred operated cases, of which he operated upon twenty-five. He lays emphasis on the marked absence of relapse in the cases so treated, and believes, while admitting a lack of definite proof, that sterility is largely obviated by surgical treatment. He gives a clear description of the operation, which is a simple and harmless procedure.

His conclusions in regard to this operation are as follows: (1) The relief from pain is instantaneous. (2) The internal administration of sedatives and opiates and loathsome external applications are made unnecessary. (3) The abatement of fever takes place in from twenty-four to forty-eight hours. (4) Pus and abscess formation is prevented. (5) Swelling, tenderness, and other symptoms rapidly disappear. (6) There is no tendency to relapse. (7) Only a minimum of time is lost from usual activities. (8) The percentage of cases of sterility following the disease is probably reduced.

J. DELLINGER BARNEY.

McCrae: Remote Effects of Lesions of the Prostate and Deep Urethra. *J. Am. M. Ass.*, 1913, lxi, 477. By Surg., Gynec. & Obst.

Lesions of the prostate and deep urethra are so frequently responsible for symptoms elsewhere, often in remote points of the body, that more frequent routine examinations of these organs are

necessary. The symptoms may be sexual, urinary, or referred. The writer discusses these various disturbances and reports a case of marked cardiac and gastric disorders that was unsuccessfully treated in many ways until the verumontanum was examined. The latter was found to be the real source of the reflex processes and was cured. Referred pains may occur in the legs or lower abdomen, and may simulate many conditions, all the more because there is no regularity in their distribution.

Chronic arthritis, impairment of kidney function, myocardial changes, even angina pectoris, are also associated with prostatic lesions and this possible relationship must not be lost sight of.

FAXTON E. GARDNER.

Kümmel, H.: The Diagnosis and Treatment of Early Malignant Disease of the Prostate. *Tr. Internat. Cong. Med.*, Lond., 1913, Aug. By Surg., Gynec. & Obst.

Kümmel discusses the present status of the question concerning the diagnosis and treatment of malignancy of the prostate gland in its initial stages.

Three points are enumerated as being essential for the definition of the term "initial stage"; i. e., (1) the malignant tumor must be confined to the gland proper, and there must be no involvement of the vesical mucosa or of the periprostatic tissue; (2) neither the anamnesis nor the subjective complaints nor the symptoms elicited by examination must furnish any material pointing to a dissemination into any other part of the anatomy from the original focus; and (3) it must be possible to remove the malignantly degenerated gland by any of the operative methods in use for the removal of a simply hypertrophied prostate.

Reviewing all of the available statistics, the author arrives at the conclusion that malignancy in the enlarged prostate is of a much higher frequency than has been believed heretofore.

Judging from his own experience and from the reports of other authors, Kümmel feels justified in formulating the thesis that a cancer may develop in an originally benign hypertrophy and that it is therefore imperative that in every case of hypertrophy of the prostate accompanied by pronounced symptoms, the possibility of malignancy be thought of.

The diagnosis that is the earliest possible recognition of the malignancy of a prostatic tumor is the most important and, at the same time, the most difficult problem encountered in the whole question. While it has to be admitted that the diagnosis of a cancer in the initial stage cannot be made with absolute certainty, still it is a matter of experience that in a vast majority of the cases of this kind the diagnosis can be established with a probability that is very close to certainty.

As leading symptoms in the recognition of prostatic cancer in its initial stage are quoted the sudden appearance of marked dysuria, irradiating pains

that have their beginning in the prostatic region, a characteristic hardness of the gland either extending over the entire tumor or restricted to certain regions of the gland, and extreme sensitiveness to touch of the parts involved.

As the method for operation the author recommends the suprapubic route. For patients who show symptoms of insufficiency of the renal function, the two-step operation is preferred, as it gives the kidneys a chance to recover after sufficient drainage has once been established.

The author sums up his conclusions as follows:

Cancer of the prostate is a relatively frequent disease; apparently simply hypertrophied glands show malignant degeneration in from twelve to twenty-three per cent of all the cases, the figures varying according to the different material of the different authors.

Cancer of the prostate shows a decided inclination to form metastases in the bones; however, a great many cases come under observation in which, during the early stage, the cancer remains confined entirely to the prostate gland.

Cancer of the prostate in its early stage may be diagnosed in the majority of cases with near certainty and in a smaller number of cases with great probability. In only a few cases will the diagnosis remain very uncertain.

The statistics of the operations prove that lasting results of eight years' duration are within our reach; in a great number of cases the condition of the patients remained satisfactory after the operation for a varying time until the relapse became manifest.

Considering that prostatic cancer in many cases remains during the initial stage an entirely local process, and that in the majority of the cases the malignancy may be recognized, it is imperative to arrive at such a diagnosis as early as possible and to attempt a radical cure by an early operation.

Considering that not only may a cancer develop in a so far normal gland, but that apparently in the majority of cases it becomes established in an already hypertrophied gland, an early removal of the prostate is to be recommended in every case of hypertrophy, if the slightest suspicion of malignancy is aroused.

The reported lasting operative results extending over periods from three to nine years seem to prove that an early operation is apt to furnish a radical cure for prostatic cancer.

In the early stage of prostatic cancer the ordinary methods employed in the removal of a hypertrophied gland are sufficient; more extensive operations are not required in the initial stage.

In case of insufficient renal function, the two-step operation should be given the preference as it is the least dangerous procedure. In order to prevent the occurrence of relapses, radiotherapy should be employed following the eradication of the gland; relapses should be treated in the same manner.

G. KOLISCHER.

Deaver, J. B.: Prostatectomy. *Surg., Gynec. & Obst.*, 1913, xvii, 157.
By Surg., Gynec. & Obst.

The enucleability of hypertrophied prostates is largely dependent upon the pathological change that is present in the particular case. The encapsulated and therefore enucleable adenomatous masses, markedly enlarged in the vertical axis and for this reason more accessible from above, are removed with surprising ease by the suprapubic route. The dense, fibrous type, which comprises about 15 per cent of benign hypertrophies, lacks not only this comparative accessibility, but, what is of greater importance, lacks also an excapsulation that permits of its being shelled out.

The cystoscope is the most valuable means of determining the most appropriate operative procedure. By its use we learn the relation of the enlarged gland to the internal vesical orifice and the degree of intravesical projection; also the condition of the bladder mucosa, the presence or absence of diverticulation, the location of calculi, their size and shape and whether free or encysted. All of these factors influence to a degree the choice of operative procedure.

Benign hypertrophies of the prostate are indistinguishable from carcinoma in its early stages. In all cases of acute or chronic retention that are impossible to catheterize, in severe cystitis, and in all cases in which for any reason it is impossible to form a fair estimate of renal function, we must limit ourselves to the drainage operation, reserving prostatectomy for future consideration.

Our advocacy of the suprapubic route is tempered with the principle that successful prostatic surgery depends upon one's ability to recognize the types best suited for, and one's skill to perform, either operation. Where the prostate is doubtfully malignant, tubercular, or the seat of incurable gonorrhœa, and where there is benign scirrhous enlargement — in all of which conditions the gland is non-enucleable because it is not encapsulated and is difficult or impossible to reach from above; the normal capsule and sheath are inseparably adherent and bound down to the surrounding levator ani muscles and pelvic fascic; and the bladder is small in capacity and has rigid walls — prostatectomy can be performed successfully only by the perineal route.

Hæmorrhage following operation is usually insignificant in amount and easily controlled with hot irrigations, but in the event of excessive bleeding the prostatic cavity must be packed with gauze.

The drainage tube should be of large calibre and so placed that the siphonage of the bas-fond is proven perfect before the patient leaves the table. The tube must have lateral and terminal openings to lessen the danger of its obstruction by a fold of mucous membrane. In exposing the bladder, a point of much practical importance is incision of the prevesical fat rather than the tearing through of this structure.

Uræmia and suppression of urine occur at times in spite of careful selection of cases and judicious

judgment both before and after operation. Hicoughing and nausea are the danger signals.

Cabot, H.: Suprapubic Prostatectomy. *Surg., Gynec. & Obst.*, 1913, xvii, 213.

By Surg., Gynec. & Obst.

This paper is a discussion of the anatomical basis for the operation of prostatectomy.

Consideration is confined to the class of cases of enlargement that is ordinarily spoken of as hypertrophy. This process is not to be regarded as true hypertrophy but as due to the formation of adenomatous nodules involving only certain lobes of the gland. Stress is laid on the fact that these adenomas do not involve the posterior lobe. The adenomatous masses which arise from the lateral and median lobe are covered on their urethral surface only by thinned true capsule and atrophied mucous membrane, from within which they cannot be enucleated even by dissection. The author shows that in the operation of prostatectomy performed by any method, only the adenomatous masses in the lateral and median lobes are removed and that the posterior lobe is not enucleated. He then compares the method of intra-urethral enucleation, whether done from above through a suprapubic incision or from below by opening the urethra in the membranous portion, with the operation of Young, which attacks the adenomas through incisions on the posterior surface of the prostate. By the intra-urethral method the adenomatous masses are removed easily and completely without damage to the posterior lobe. By the operation of Young the removal of the lobes from under the thinned capsule and mucous membrane is exceedingly difficult and often incomplete. Furthermore, in Young's operation the structures of the posterior lobe are necessarily damaged extensively.

The author therefore is of the opinion that Young's operation cannot properly be regarded as a conservative method. The suprapubic method of approach is open to fewer objections on the ground of unpleasant sequelæ such as fistulæ and lack of urinary control than is the perineal approach, and accordingly is to be preferred.

Day, G. H.: A Modified Drainage for Suprapubic Prostatectomy. *N. Y. M. J.*, 1913, xcvi, 425.

By Surg., Gynec. & Obst.

The author has suggested a modification of Dawbarn's system syphonage for suprapubic drainage. In using the Dawbarn system, the author passes the bladder catheter through the center of a Marion

1, Catheter for irrigating purposes. 2, Marion tube. 3, Metal stopper. 4, Drainage tubing. 5, Glass connecting tubing. 6, Soft rubber drainage tubing. 7, Glass. 8, Irrigating tubing. 9, Regulating cut-off. 10, A large irrigator. 11, Irrigating tubing. 12, Receptacle for waste. (Day.)

suprapubic tube before he begins the syphonage. If he wishes bladder irrigation in addition, he simply irrigates through the small tube attached to the side of the Marion tube.

SURGERY OF THE EYE AND EAR

EYE

Robertson, E. N.: The Present Approved Methods of Treatment of Obstructions to the Lacrimo-Nasal Duct. *J. Kansas M. Soc.*, 1913, xiii, 279.
By Surg., Gynec. & Obst.

Robertson discusses the treatment of obstruction of the nasal duct and sums it up as follows:

"The majority of all cases of lacrimo-nasal obstruction, in the beginning, can be relieved by very simple measures.

"Syringing with mild astringent antiseptic solutions should always be tried faithfully, even in those cases where a mucopurulent discharge from the sac is present.

"It is better as a rule not to open an acute dacryocystitis through the skin. More satisfactory final results are obtained by letting the pus out through the canaliculus, or by the incision of Agnew, followed by the use of the probe.

"Rapid dilatation by the method of Ziegler is sufficient to effect a cure in many cases formerly made tedious by probing.

"Good results can be accomplished by probing in selected cases if the patient will stand for it.

"When quick relief to chronic dacryocystitis is desired, extirpate the lachrymal sac."

C. G. DARLING.

Coats, G.: Infarction of the Posterior Ciliary Arteries. *Tr. Internat. Cong. Med.*, Lond., 1913, Aug.
By Surg., Gynec. & Obst.

Coats describes the pathological details of two cases in which a wedge-shaped portion of the inner layers of the sclera at the posterior pole was necrotic. A somewhat larger area of the choroid, and a still larger area of the retina, were similarly affected. There was no fusion of the choroid and retina, but a moderate amount of infiltration was present in the surrounding tissues. In the divided eye the area appeared as an atrophic patch 8 to 10 mm. in diameter. It had not been seen with the ophthalmoscope, the cases showing clinically the symptoms of a chronic iridocyclitis. The author points out that the pathological features of these cases differed from those of an ordinary patch of choroidoretinitis in the great preponderance of the necrosis over the inflammatory reaction, and in the absence of fusion of the two tunics. An inflammation severe enough to give rise to such a degree of necrosis must have been accompanied by a large amount of plastic exudation, whereas, as a matter of fact, the signs of inflammation were quite moderate. Therefore the necrosis must have been due only to a cutting off of the blood supply. This supposition was accompan-

ied by the localization of the patch which corresponded well with the distribution of a main posterior ciliary artery. The condition was indeed an infarction of a posterior ciliary artery, and it had the wedge shape which is usual in infarctions elsewhere.

Infarctions of this kind give rise to toxine which cause a certain amount of inflammatory reaction in the surrounding tissues, leading to encapsulation and penetration of the dead tissue with organizing material. In the cases reported it is probable that similar substances diffused forwards through the vitreous, and gave rise to the iridocyclitis which was the chief clinical symptom. It might seem surprising that necrosis *en masse* should occur in so vascular a tissue as the choroid, but it should be remembered that the vitality of a tissue after the obstruction of its blood supply depends not simply on its vascularity, but also on the freedom with which blood from collateral sources can be poured into it. Thus the kidney and spleen are highly vascular organs, but owing to peculiarities in the distribution of their vessels, are subject to infarction. Similarly, in the choroid it had been shown by Leber that the larger ciliary arteries have few branches of communication. The necrosis of the retina, which has a blood supply of its own, is easy to account for. Probably the element of suddenness had something to do with the matter, and perhaps the toxins produced by the necrotic tissue were not without influence. A similar complete necrosis is found on dividing the posterior ciliary arteries in the rabbit.

The presence of necrosis in bulk proved that the obstruction must have been sudden, for gradual blockage of ciliary vessels produces a different and sufficiently well known set of phenomena. The block therefore could not have been due to endarteritis alone, but must have been caused either by thrombosis or embolism. Unfortunately, no details are available as to the cardiac condition of the patients.

Harman, N. B.: The Results of the First Hundred Squint Cases Operated Upon by the New Method of Subconjunctival Reefing and Advancement, with Lengthening of the Antagonist where Necessary. *Tr. Internat. Cong. Med.*, Lond., 1913, Aug.
By Surg., Gynec. & Obst.

In this operation the tendon is not cut or exposed to view. The upper and lower edges are cleared by two button-holes cut through the conjunctiva and capsule. The tendon is freshened by a rasp. Special forceps of simple design are then passed into the button-holes to secure the tendon. The movement

of the forceps folds the tendon into plaits. The ree is sewed up or advanced as the case indicates, or the antagonist is lengthened by a graduated partial tenotomy.

The steps of the reefing advancement are as follows: (1) The eye is secured with an anchor stitch placed at the limbus in the axis of the tendon to be shortened; (2) the position of the tendon is noted; it is pointed out that there are well-defined surface markings and color differences; (3) the button-holes are cut above and below the tendon edge close to the canthus; (4) the tendon is lifted and both surfaces are rasped with the instrument provided; (5) reefing forceps are applied, adjusted to the extent of shortening required, and rotated; (6) the reef is sewed up by the blanket stitch; and (7) the reef is advanced by fixing stitches into the limbus.

The author points out that attempts to secure a large effect by shortening one tendon caused permanent enophthalmos. This was preventable by lengthening the antagonist, which was done by a graduated partial tenotomy — the "jigsaw" operation. The tendon was exposed, secured in "director-forceps" which checked the bleeding and afforded a marked guide to the incisions. Three cuts were made, one severing two thirds of the middle cut. The tendon thereupon extended lengthwise without loosening its attachments or alignment. The author shows how the cuts can be varied so as to secure vertical deviation also.

Results: Of the first 100 serial cases including the earlier experimental operations, the results obtained after an average interval of nine months were: Binocular vision, 4; straight, 36; error less than 3 degrees, 22; error 5 degrees, 23 (these make 85 per cent successes); error 10 degrees, 9; error from 10 to 20 degrees, 4; relapse six months after operation during severe keratitis, 1, and overcorrection found six months after operation, 1.

The technique of the operations was demonstrated on a dummy devised for the purpose.

Bulson, A. E.: The Cause and Treatment of Convergent Squint. *J. Indiana St. M. Ass.*, 1913, vi, 357.

By Surg., Gynec. & Obst.

Bulson reviews the cause and treatment of convergent squint and states that the proper treatment includes: (1) The recognition of the necessity of giving attention at the beginning of the squint. (2) The correction of the refractive error. (3) Orthoptic training. (4) Operative treatment. He then takes up these points in detail. C. G. DARLING.

Heath, F. C.: Sympathetic Ophthalmia with Recovery. *J. Indiana St. M. Ass.*, 1913, vi, 364.

By Surg., Gynec. & Obst.

Heath reports the case of a man whose eye had been injured by a piece of steel which was removed from the vitreous thirteen days after the injury by means of a magnet. Two weeks later the eye was enucleated. Four days later the good eye became

inflamed. There were pigment spots on Descemet's membrane and vitreous opacities. A few days later the eye was much worse. There was marked oedema and severe pain. Vision was nearly abolished.

The treatment given was sodium salicylate, 360 grains a day, inunctions, and finally a hypodermic of pilocarpine grains .1 and nitroglycerine grains .01. During the period of treatment atropine and dionin were used locally. The day following the hypodermic, the patient was salivated and great improvement took place in the eye. The treatment was continued until vision was normal. C. G. DARLING.

Smith, P.: Glaucoma Operations. *Tr. Internat. Cong. Med.*, Lond., 1913, Aug.

By Surg., Gynec. & Obst.

The report shows the extent to which the newer operations for glaucoma have supplanted the classical iridectomy in the practice of British ophthalmic surgeons. In the autumn of 1912 the author addressed an inquiry on the subject to all members of the Ophthalmological Society of the United Kingdom excepting those known to do no operative work. The replies showed that iridectomy, variously executed, still holds an almost undisputed place in the treatment of acute glaucoma, but that in chronic glaucoma operations expressly designed to establish a subconjunctival fistula or filtering cicatrix, and pre-eminently sclerocorneal trephining, have replaced it to a very large extent. Evidence for and against the various procedures is given.

Roy, D.: Observations on Operations for Glaucoma. *South. M. J.*, 1913, vi, 525.

By Surg., Gynec. & Obst.

Roy discusses some of the operations for glaucoma and reports good results in the three cases on which he performed Borthen's operation for iridotaxis. He says:

"These results, while few in number, have been so gratifying and so much better than I had obtained previously with the operation of iridectomy that I must say I hold the operation in high esteem. The simplicity of its technique and the absence of all signs of irritation following the same certainly commends it to the inexperienced operator. The only criticism that could be made is the fact it has not been tried long enough to satisfy us as to its permanent value, and the fact that a prolapsed iris is supposed to make a dangerous eye, especially in producing a sympathetic ophthalmitis. In none of Borthen's cases was there the slightest trouble."

C. G. DARLING.

EAR

Dench, E. B.: Two Cases of Loss of Caloric Vestibular Reaction, with Operative Findings. *Tr. Internat. Cong. Med.*, Lond., 1913, Aug.

By Surg., Gynec. & Obst.

The first case was that of a woman, twenty-four years of age, who had suffered from a chronic middle-

ear suppuration since childhood. There was a history of an acute exacerbation of the aural symptoms two weeks before the patient came under observation. The symptoms comprised severe pain in the ear, tinnitus, dizziness, nausea, and vomiting. The nausea and vomiting were severe at first, but gradually disappeared. The patient was unsteady on standing, and, apparently, fell backward and to the affected side. All other signs were negative. The caloric reaction upon the affected side was noted when the patient was admitted to the hospital, but twenty-four hours later the left labyrinth did not react. Twenty-four hours after admission the patient had a tendency to fall on walking and jumping to the side opposite to the lesion. On account of the sudden loss of the caloric reaction, an increase in the dizziness, and a gradual rise in temperature to nearly 101° , it was decided to perform the radical operation. At the time of the operation a fistula was found in the horizontal semicircular canal, and the oval window also was found open. A complete labyrinth operation was performed according to the Neumann method, and an uneventful recovery resulted.

The second case was that of a boy, fourteen years of age, who had had a discharge from the right ear for six months. As the result of local treatment, this discharge ceased four months after its appearance. Six months after it was first noted the patient returned to the hospital, complaining of severe pain in the right ear and above the insertion of the sterno-mastoid muscle. There was no discharge from the ear. He complained also of headache and dizziness. The left ear was practically normal. There was some granulation tissue in the right tympanic cavity. The boy was admitted to the hospital and the granulation tissue was removed. There was practically no rise in temperature. A caloric test at the time of admission to the hospital showed a normal labyrinth upon each side. The granulation tissue from the right tympanic cavity was removed, and twelve hours later the temperature was 104° . It remained at this level for eight hours. An examination of the right labyrinth showed a negative reaction to the caloric test. Cerebrospinal fluid obtained by spinal puncture was found to be normal by both a cytological and a chemical examination. A blood culture showed streptococci in the blood.

On account of the high temperature, and the absence of meningeal symptoms, a radical operation was performed. The lateral sinus was exposed and found to be filled with an old clot. The internal jugular was excised from a point just below the omohyoid muscle to the base of the skull. The sinus was thoroughly opened and curetted until free hæmorrhage occurred from both the torcular and the bulbar extremities of the sinus. The temperature fell after the operation, and certain pulmonary symptoms, indicative either of a beginning pleurisy or a beginning pneumonia, appeared. This seemed to account for the slight rise in the tempera-

ture, for the cerebrospinal fluid remained normal. On the fifth day after operation there was a sudden rise in the temperature, and cultivation of the fluid showed long chains of streptococci. On the following day a lumbar puncture showed globulins in excess, and pus, blood, and streptococci in the cerebrospinal fluid. A complete labyrinth operation was then performed. Immediately after the operation the temperature fell, but the patient died suddenly, with the symptoms of pulmonary embolism.

The first case demonstrates the satisfactory results of prompt operative interference in cases of beginning acute labyrinthitis.

In the second case the lesion was a mixed lesion; that is, there was a sinus thrombosis of long duration, and a sudden involvement of the labyrinth with extension to the meninges. The author believes there is no question but that the labyrinthine involvement was secondary to the jugular thrombosis. The infection probably spread either through the aquæductus vestibuli or the aquæductus cochleæ which lie in close proximity to the lateral sinus and the jugular bulb. The operative interference in the second case would probably have been successful had not pulmonary embolism occurred.

Shambaugh, G. E.: When to Operate on the Labyrinth in Labyrinth Infection Secondary to Purulent Otitis Media. *Ann. Otol., Rhinol. & Laryngol.*, 1913, xxii, 303. By Surg., Gynec. & Obst.

The author states that in view of the fact that accurate observation of cases of labyrinth infection is still comparatively new, and that a large number of cases of labyrinth empyema recover spontaneously, it is difficult as yet to lay down definite indications for operation to cover all cases.

He considers a labyrinth operation clearly indicated in cases of labyrinth suppuration where a beginning intracranial complication has developed; when it is part of an acute or chronic suppurative otitis media and there are indications for a mastoid operation; and in cases complicated by an erosion of the labyrinth capsule, fistula formation into the labyrinth, facial paralysis, or sequestration of a part or of the whole of the labyrinth capsule.

ELLEN J. PATTERSON.

Botey, R.: The Trephination of the Labyrinth for Vertigo and Buzzing in the Ear (Le trepanation du labyrinthe pour vertiges et bourdonnements). *Tr. Internat. Cong. Med.*, Lond., 1913, Aug. By Surg., Gynec. & Obst.

Operations on the labyrinth for non-suppurative affections of the semicircular canals and cochleæ have not become general. Botey discusses the value of such operations. In patients affected with vertigo and intolerable buzzing in the ears, the lesion is generally in the termination of the cochlear division of the nerve in the cochlea or of the vestibular branch in the ampulla. In such cases, operation on the vestibule and cochlea is effective, and the author describes two cases of his own which were

thoroughly successful. On the other hand, the seat of the trouble may be in the auditory nerve at the base of the brain, in which case a labyrinthine operation will do no good. Botey describes a case of his own, which was unsuccessful. The patient had syphilis. The majority of the cases with a central lesion are syphilitic. Intracranial section of the auditory nerve has been suggested and carried out in a few cases. Three cases are cited in which there was only slight relief or recurrence. In view of the danger of the operation and the small hope of success, he considers that this procedure is not justified. He approves of the operation on the labyrinth, as it is not dangerous, and believes that it should be performed when the condition has not yielded to a reasonably long period of treatment and when the patient must work.

Botey, R.: Anatomical Preparations to Illustrate Trephining of the Labyrinth (Quelques préparations anatomiques de trépanation du labyrinthe). *Tr. Internat. Cong. Med.*, Lond., 1913, Aug.

By Surg., Gynec. & Obst.

Botey makes anatomical preparations of the temporal bone which he uses in his classes to illustrate the various operations on the labyrinth. The places of opening are painted in red and the cavities of the labyrinth are tinted blue. Twelve preparations are described, demonstrating:

1. Old method. Trephining of the horizontal canal through the the fenestrum ovale with enlargement of the latter.
2. Jansen-Neumann method. Resection of the posterior wall of the petrous portion; opening of the canals and of the vestibule. Sigmoid sinus indicated.
3. Bourguet's method. Separate opening of the external, posterior, and superior canals. Opening of the vestibule and cochlea through the tympanum.
4. Botey's method. Opening of the ampulla of the external canal, of the posterior canal, of the posterior wall of the vestibule, of the anterior extremity of the superior canal. Defenestration.
5. Hautant's method. Opening of the ampulla of the external canal and of the vestibule from behind.
6. Ruttin's method. Tunneling behind mastoid, opening of the posterior wall of the vestibule. Defenestration.
7. Opening of the vestibule from behind, and of the ampulla of the external canal, the anterior extremity of the superior canal and the vestibule and cochlea through the tympanum.
8. Opening of the vestibule through the tympanum, without defenestration and after extensive chiseling out.
9. Opening of the external canal and the vestibule from behind after antrotomy without chiseling or defenestration.
10. Opening of the vestibule from behind without defenestration, leaving the ossicles and the external wall of the attic intact.
11. Atypical operation (unpublished case). Opening of the vestibule after resection of the posterior wall of the petrous portion on account of lack of room. Opening of the middle cerebral fossa (abscess). The sigmoid sinus is prolapsed.
12. Specimen demon-

strating the liability of injuring the facial nerve, which is colored yellow, by excavating the posterior part of the mastoid.

A. Goss.

Mouret, J.: The Surgical Anatomy of the Mastoid (L'anatomie chirurgicale de la mastoïde). *Tr. Internat. Cong. Med.*, Lond., 1913, Aug.

By Surg., Gynec. & Obst.

The author traces the limits of the surgical mastoid region, studying its structure and the anatomical relations that make surgical intervention in this region such a delicate procedure.

The surgical mastoid differs from the anatomical mastoid in that it comprises not only the mastoid process, but all the temporal region back of the external auditory meatus, the tympanum, and the semicircular canals. The author outlines an area on the temporal bone which he calls the mastoid region, and studies in detail its form and the anatomical relations of each surface as well as the internal structure.

The external surface, which is *par excellence* the operative region, is studied with special care from both descriptive and topographical points of view.

The relations of the deep parts of the mastoid region to the external surface are demonstrated by means of horizontal sections which enabled the author to establish very definitely the topography of this region and divide it into an antral zone, a subantral zone, an apical zone, an intersinuso-antral zone, a sinal zone and a cerebellar zone. The normal and abnormal locations of these zones and their relations to the character of the bone (cellular, spongy or compact) are studied.

The development of the antrum, its normal and abnormal locations, and trephining of the antrum are given a special chapter. The author describes a method which he calls trans-spina-meatal trephining. It has the advantage over the classic procedure in that it enters the antrum by the shortest and safest route, and reduces to a minimum the danger of injuring either the descending lateral sinus or the facial nerve.

Bryant, W. S.: Management of Mastoid Wounds.

Tr. Internat. Cong. Med., Lond., 1913, Aug.

By Surg., Gynec. & Obst.

The final results after a mastoid operation depend very largely on the management of the mastoid wound. What subsequently befalls this wound, whether it heals quickly with a minimum of scar, a minimum of distress to the patient, and a maximum increase of hearing, depends even more upon the technique of the post-operative care of the wound than upon the technique of the operation. The post-operative treatment must be adapted to meet one of two different events: first, nature's promising attempts to heal the wound must be encouraged; or second, if nature fails, the unsuccessful attempts at healing must be guided. In the first event, our aim is to interfere with the natural process as little as possible; having closed and united the surfaces of

the wound, our sole object is to prevent infection from without. In the second event, various contingencies require attention: (1) Collections of fluid (serum or blood) under pressure within the wound have to be released by a filiform drain or by probing. (2) Collections of pus must be evacuated by probing. (3) Necrosis must be controlled by moist antiseptic dressings and powders. (4) Redundant granulation tissue must be restrained. Granulations are best avoided by preventing infection in the wound. The easiest method of removing them is by curetting. (5) The formation of excessive scar tissue must be prevented by effecting a rapid healing. (6) Tympanic adhesions are also avoided by rapid healing; they are managed by early and repeated tympanic inflation. (7) The formation of permanent fistulæ should be prevented by the avoidance of packing and by the encouragement of cicatricial tissue. (8) In a general way, we have to hurry nature when her reparative process seems too slow. Indolent wounds are aroused by moist stimulating dressings and powders, and are aided by general tonic and specific medication when indicated.

With care and good judgment the result of a mastoid operation can be made eminently satisfactory. The convalescence is reduced to a few days, the scar and deformity become negligible, pain is obviated, and the hearing is improved.

Kramptitz: The Dangers of Ligating the Jugular Vein in Otology and the Possibility of Preventing Them (Gefahren der Jugularisunterbindung in der Ohrenheilkunde und die Möglichkeit ihrer Verhütung). *Internat. Zentralbl. f. Ohrenheilk. u. Rhino-Laryngol.*, 1913, xi, 161.

By Zentralbl. f. d. ges. Chir. u. i. Grenzgeb.

In the year 1880 Zaufal ligated the internal jugular vein for sinus thrombosis of otogenous origin. Since that time the operation has been a recognized procedure for the prevention of otogenous pyæmia. Naturally the focus in the sinus must be opened. On account of numerous other collateral branches some operators will not ligate the jugular vein. According to Stenger no operations should be performed either on the sinus or the jugular vein in the presence of acute suppurative processes within the ear. In chronic cases, especially those complicated with cholesteatomata, ligation of the jugular may be performed in addition to cleaning out the diseased area.

Air embolism and the formation of a new thrombus at the site of ligation are unpleasant complications. Fatal congestion of the brain due to anomalies or hypoplasia of the other vessels may occur. More frequent are transient disturbances of circulation accompanied by headache, cyanosis, and œdema of the side involved. Injury to the vagus nerve has been observed. Ligation of both jugulars need not be fatal. All of the dangers have not brought the operation into discredit. To prevent

the formation of an infected thrombus at the site of ligation the peripheral end of the vein has been sutured to the skin wound. To prevent the formation of sudden œdema of the brain it must be determined whether the opposite jugular vein is patent. This is done most easily by compressing the vein temporarily. The communication between both jugulars is so extensive that one may be ligated without causing much disturbance in the circulation. With bilateral compression swelling of the supraorbital and retinal veins occurs. The same results are noted if one vein is thrombosed and the other is compressed or aplastic.

PAETZOLD.

Jacques, P.: Pharyngeal Drainage of Cranial Suppurations of Otogenous Origin (Sur le drainage pharyngien des suppurations crâniennes d'origine otique). *Tr. Internat. Cong. Med.*, Lond., 1913, Aug.

By Surg., Gynec. & Obst.

Otogenous retro-pharyngeal abscess may have three origins: (1) Adenophlegmon (in 10 per cent of cases, according to the author); (2) the rupture of the floor of the tympanum or of a sublabrynthine cell (44 per cent); and (3) the migration of a nuchal abscess secondary to pachymeningitis (46 per cent).

The author explains the mechanism of this latter variety from two cases of his own with dissection and anatomical sections. The starting point is prolonged suppuration around the sinuses which finds its exit from the skull through the anterior condyloid foramen or even through the occipital bone perforated at its thinnest point back of the condyle.

Outside the skull the pus tends to infiltrate the cellular interstices of the neck, following the occipital artery and its accompanying nerves and veins. Its progress toward the pharynx is cut off by a resistant musculo-aponeurotic barrier extending transversely between the mastoid and the condyle, and vertically between the jugular process of the occipital and the lateral mass of the atlas. It is composed from without inward of the parotid aponeurosis, the styloid process and its muscles, and the rectus capitis lateralis and its aponeurosis which covers the vessel sheaths in front. A somewhat exceptional anatomical condition favors the transmission of the pus toward the pharynx. This is the presence of an intermediate condyloid foramen which transmits a venous channel through the aponeurosis of the rectus capitis lateralis, anastomosing at the external orifice of the anterior condyloid foramen with the plexus of the hypoglossal nerve.

The author believes that the discharge of the pus through the pharynx is favorable because it gives permanent sloping drainage to a collection which is imperfectly evacuated by the freest incision through the nape of the neck. He therefore proposes to favor this "fortunate complication" by cautiously scraping the aponeurotic attachment of the right capitis lateralis to the occipital condyle. A. Goss.

SURGERY OF THE NOSE, THROAT, AND MOUTH

Marschick, H.: Pathology and Diagnosis of Malignant Diseases of the Nose and Nasopharynx. *Tr. Internat. Cong. Med.*, Lond., 1913, Aug.
By Surg., Gynec. & Obst.

Owing to the bad prognosis of malignant tumors of the nose and nasopharynx, many rhinologists have given up operating on these cases. These tumors are fatal because they are located near important organs and in a region of complicated structures. The clinical malignancy is often more important than that demonstrated pathologically. In this article tumors of the nose and accessory sinuses are treated in one group and those of the nasopharynx in another.

1. About 800 cases of malignancy of the nose and sinuses are cited from the literature. Theories of cause relate to chronic irritation, mechanical or chemical, or to changes in the cells without external influence. The relation of empyema or benign tumors (polypi especially) to malignancy is considered. Histologically, the sarcoma is most frequent. They arise usually from the periosteum or bone, with a predilection for the septum or anterior half of the middle turbinate. Carcinomas are most malignant. They originate from the epithelium, the glands, or paradental germinal cells.

Symptoms are often late, the onset usually coming with obstruction and regional pain. Hæmorrhage, eye or brain involvement, often follow. Metastases, except in the regional lymph glands, are rare. Death often results from cerebral complications or hæmorrhage before cachexia has become marked.

2. In the nasopharynx malignancy is less common. Carcinoma prevails and endothelioma is more frequent than in the nose. Lympho-sarcoma originating in the pharyngeal tonsil is not rare. Symptomatically there is a long latent period. At the onset there is cough, deafness, and involvement of the cranial nerves, especially the lower branch of the trifacial; then occipital pain and paralyses. Distant metastases are formed only occasionally. The ease with which hæmorrhage may be started makes the removal of a portion dangerous.

EARLE B. FOWLER.

Kocher and Horand: The Temporary Resection of the Superior Maxilla for Ossifying Chondroma of the Nasopharynx (Sur un cas de résection temporaire du maxillaire supérieur pour un chondrome ossifiant du naso-pharynx). *Lyon chir.*, 1913, x, 135.
By Journal de Chirurgie.

The authors report a case as an example of the usefulness of temporary resection of the superior maxillary as a means of approach to the upper pharynx. Their patient, aged 29, for some months

had had violent headache and signs of progressive bilateral nasal obstruction. On both sides there was symmetrical ophthalmia and paresis of the muscles of the eye, which was most marked in the internal rectus (external strabismus). Examination showed behind the velum a hard, rough tumor filling the pharynx. It did not bleed and did not yield to pressure.

Jaboulay first ligated the right external carotid, and then resected the superior maxillary and lifted it upward and outward. This resection gave very free access to the tumor, which was as large as the fist. The tumor was extirpated along with an orbital prolongation the size of a hazel-nut. The maxillary was then replaced and fixed by ligature of the incisors and the suture of the molar.

The tumor was made up of irregularly distributed layers of cartilage and osseous tissue separated by fibrous bands.

The patient recovered and the cosmetic result was good. The recovery was retarded for a long time, however, by an abundant suppuration which decreased only after the elimination of a large sequestrum involving the alveolar border and the vault of the palate. The right half of the vault of the palate was necrosed. Between the mouth and the nasal cavities and sinuses there was a large opening which caused a marked nasal tone.

CH. LENORMANT.

Iglauer, S.: Some Attempts at the Intranasal Transplantation of Nasal Tissues. *Ann. Otol., Rhinol. & Laryngol.*, 1913, xxii, 308.

By Surg., Gynec. & Obst.

After a limited series of experiments on animals, the author finds that though there are no technical difficulties in the transfer of intranasal tissue from one individual to another of the same species, the surface transplantation will probably fail on account of infection. The submucous transplantation yields better results.

From his clinical experiments he finds that while surface transplantation is not very successful, the submucous transplantation of nasal mucous membrane and underlying bone can be carried out with good prospects for the survival of the transplant, but that the latter tends to become absorbed.

ELEN J. PATTERSON.

Beck, J. C.: Removal of Adenoids by Direct Inspection. *Ann. Otol., Rhinol. & Laryngol.*, 1913, xxii, 273.

By Surg., Gynec. & Obst.

The author claims that by his method of retracting the soft palate, adenoids can be removed by direct inspection under ether anæsthesia more thoroughly

especially around the Eustachian orifice. At the same time the primary tonsillar hæmorrhage can be controlled.

The technique of the operation is as follows: One of the free ends of a small rubber catheter is passed through each nostril and withdrawn through the mouth. After the tonsils are removed, the catheter is drawn taut, one end over each cheek. This brings the pillars into apposition, controls the tonsillar hæmorrhage, and exposes the nasopharynx. With the head extended and the pharyngeal reflex abolished, the adenoid mass can be seen and removed by direct inspection by the method approved by the operator.

ELLEN J. PATTERSON.

Goodale, J. L.: Indications for and the Relative Value of Tonsillotomy and Tonsillectomy.

Tr. Internat. Cong. Med., Lond., 1913, Aug.

By Surg., Gynec. & Obst.

It has not been demonstrated that complete removal of the tonsils is followed by a harmful effect upon the general system.

Tonsillotomy involves usually less trauma than does tonsillectomy, but in the latter the method of removal is of primary importance. A sharp dissection down to the tonsillar artery, with snaring of the vessels, gives the least amount of inflammatory reaction.

Of the two operations, tonsillectomy shows a larger percentage of septic complications, because of the greater trauma it usually occasions, and also the relatively larger number of septic conditions under which of late years an operation is undertaken.

The relative frequency of post-operative hæmorrhage is not definitely established, but in view of the available methods of treatment, it is no longer a serious complication if dependent upon local causes.

While gross deformities of the parts involved are not likely to follow tonsillotomy, cicatricial occlusion of the lacunar orifices is frequent, and may lead to an intensification of the original chronic inflammation. Tonsillectomy in unskilled hands may be followed by marked and injurious distortion, but with good technique should have no other alteration than an approximation, and occasionally, a partial fusion, of the pillars.

The indications for operation should be such pathological changes of the tonsils as are actually a detriment to the individual.

Simple hyperplasia, if obstructive or favoring catarrhal conditions, and if persistent, may be sufficiently treated by a tonsillotomy, especially in children.

The systemic ill effects of chronic tonsillitis may be increased by a tonsillotomy. In such cases, complete removal is preferable to a partial removal, although mild cases of chronic inflammation may be sufficiently relieved by appropriate treatment without excision.

Infection of the fauces due to micro-organisms may not be prevented by removal of the tonsils.

Recurrent local infections or general infections

having their origin in the tonsils require tonsillectomy as soon as a favorable moment for operating arrives. Tonsillotomy may be expected here to prove inadequate.

Recurrent acute catarrhal infections of the throat require complete removal of the tonsils if these show chronic inflammation, although immunity against subsequent attacks is not necessarily secured.

Local tuberculosis of the tonsil requires complete removal of the organ.

In young children with adenoid enlargement requiring removal, the tonsils should not be excised unless they cause demonstrable injury or favor attacks of acute middle-ear inflammation.

If an impairment of the speaking voice is dependent upon tonsillar disturbances, these may be corrected according to the principles already given, and if a tonsillectomy is indicated, it may be performed with proper technique without anxiety.

In singers, slight alteration in the tension of the palatal muscles may influence the voice either favorably or unfavorably. In the case of beginners with harmful alterations of the tonsils, a partial or complete removal may usually be effected if the local or general welfare of the patient demands it. With increasing length of singing experience a correspondingly conservative attitude should be maintained, particularly in respect to truly fine voices.

De Santi, P. R. W.: The Pathology of the Various Acute Inflammations of the Throat and Neck Including Acute Œdema, Phlegmon, Erysipelas, and Angina Ludovici, but Excluding Diphtheria.

Tr. Internat. Cong. Med., Lond., 1913, Aug.

By Surg., Gynec. & Obst.

This paper was a report of eight cases of acute septic inflammations of the throat in which bacteriological examinations were made. The cases were as follows: (1) erysipelas of the pharynx; (2) acute septic inflammation of the tonsils and pharynx; (3) acute gangrenous inflammation of the throat; (4) acute pharyngitis due to streptococcus pyogenes followed by septicæmia, deep glandular inflammation, and pericarditis; (5) acute suppurative inflammation of the larynx; (6) acute œdematous septic laryngitis; (7) acute septic inflammation of the tonsils and pharynx; and (8) acute septic inflammation of the pharynx, tonsils, and buccal mucous membrane with inflammation of the submaxillary cellular tissue.

All of the patients except one were adults in the prime of life. The one exception was a boy 12 years of age. All of the patients were males and previously had been in excellent health. Five of them were hospital patients, and three, private patients. In all, the streptococcus predominated in the cover-glass preparations and cultures. Six of the cases were treated with some form of antistreptococcus serum; one case had an autogenous vaccine in addition. In one case the subsequent history is unknown as the patient refused to enter the hospital. In

another case serum and vaccine treatment were refused, but the patient recovered. In three cases the prognosis was very unfavorable (Nos. 3, 4, and 8). All of the six cases treated made excellent recoveries as did also the patient who refused serum treatment.

The history, clinical symptoms, the course of the disease, and more particularly, the bacteriological examination of this series of cases indicate their pathological identity and point to the conclusion that each one should be considered as showing merely a different degree of virulence of one and the same pathological process. The micro-organisms that are the chief causative factor belong to the streptococcus pyogenes group. Other organisms, however, may be, and are, found; not infrequently more than one organism is present. There is, however, no one specific organism for every one of these various inflammations. The different localization of these septic inflammations depends upon the resisting powers of the parts attacked. An accidental breach of the surface or a pre-existing condition of catarrh renders a part more susceptible to infection.

The prognosis of such cases is always very grave. The sooner this fact is recognized by the general practitioner, the better. Heart failure is the great danger and it is by no means uncommon for a fatal issue to result in twenty-four or forty-eight hours from the outset of the malady. Ludwig's angina should be included in this class of cases and is particularly dangerous to life. In addition to the usual methods of treatment, citric acid in 60 gr. doses may be prescribed to lower the coagulability of the blood so that the lymph that contains large amounts of antibacterial and antitryptic bodies may be freely admitted to the infected parts and the organisms thereby destroyed before the formation of pus.

The main points in the treatment of these inflammations are early recognition, a skilled bacteriological examination, including examination of the blood, and isolation if possible of the offending micro-organism, and serum or vaccine treatment.

A serum should be given as early as possible. It should, moreover, be of a type that most nearly

approaches the autogenous variety. Following the use of a serum or in combination with it an autogenous vaccine should be given as soon as prepared.

The author attributes the recovery of all of his cases to treatment along these lines.

Botey, R.: The Best Method for Extirpating the Larynx (Quelle est la meilleure méthode d'extirpation du larynx?) *Tr. Internat. Cong. Med.*, Lond., 1913, Aug. By Surg., Gynec. & Obst.

Botey discusses the various methods of laryngectomy and points out the advantages and disadvantages of each. The method of preference is Gluck's method. Gluck makes two lateral flaps which give a good view of the field of operation. He then cuts all vessels between two ligatures and extirpates the larynx from above downward, suturing the wound completely before separating the vocal organ from the trachea. This effectually prevents the entrance of septic liquids into the trachea. The glands are removed if they are at all diseased. The trachea is not separated from the œsophagus so there is no necrosis of the rings or gangrene of the posterior wall. This method has been more successful than any other in avoiding broncho-pneumonia and mediastinitis. Gluck reports 63 cases in which there was no death from operation. The operation without removal of the glands requires an hour; with removal of the glands, two hours. For patients who cannot stand so long an operation, Le Bec's method in two stages separated by an interval of three weeks is to be preferred. General anæsthesia is better than local except for very stoic patients. Botey uses Schleich's mixture, chloroform, ether and ethyl chloride, given with an apparatus that mixes oxygen with them automatically.

Special care should be taken in regard to asepsis, and the operation should be performed with all possible speed. The patient should be unusually well nourished before the operation. These precautions, with heat and heart tonics, will prevent surgical shock.

Intelligent and well-trained patients will learn to speak with their pharyngeal voice, and Botey has constructed an apparatus to aid them. A. Goss.

Disinfection of the skin with chlorated alcohol. PEL-LEGRINI. Rev. osp., Roma, 1913, iii, No. 14.

Disinfection by alcohol. NEDZIELNITZKY. Charkov. med. J., 1913, xvi, No. 1.

Disinfection of the field of operation with thymol alcohol. KOEHLER. Deutsche mil.-ärzt. Ztschr., 1913, xlii, No. 16.

Disinfection of the skin of the operative field and of the hands by means of alcohol and iodine. ANIKÉIEFF. J. akush. i jensk. boliez., St. Petersb., 1913, xxviii, Nos. 7-8.

Experimental chemotherapy and the problem of internal disinfection in bacterial infections. J. MORGENROTH. Naturwissenschaften, 1913, i, 609.

Rubber gloves or protective antiseptic applications. DUBARD. Bourgogne méd., 1913, xxi, No. 7.

Alcohol operating gloves. B. KOZLOWKI. Zentralbl. f. Chir., 1913, xl, 1038. [597]

Anæsthetics

Theory of narcosis. J. TRAUBE. Arch. f. d. ges. Physiol., 1913, cliii, 276.

Anæsthesia among the Indians. J. M. G. LUKAYS. Mass. M. J., 1913, 302.

Dosimetric method of administering chloroform. D. W. BUXTON. Tr. Internat. Cong. Med., Lond., 1913, Aug. [597]

Narcosis with heated ether. JULLIARD. Rev. med. Suisse romande, 1913, xxxiii, No. 8.

Three cases of generalized narcosis produced by intramuscular injection of ether. J. A. GAMOLKO. Chirurgia, St. Petersb., 1913, xxxiv, 51.

General anæsthesia by intramuscular injection of ether. M. DESCARPENTRIES. Tr. Internat. Cong. Med., Lond., 1913, Aug. [598]

Oil-ether; an attempt to abolish inhalation anæsthetics. J. T. GWATHMEY. Tr. Internat. Cong. Med., Lond., 1913, Aug. [599]

Prolonged general anæsthesia with ethyl chloride. E. GAULLAUD. Tr. Internat. Cong. Med., Lond., 1913, Aug. [599]

Mixed anæsthesia. ROSSIISKY. Vrach. Gaz., 1913, vi, No. 22.

The danger of the combination of morphine with generalized narcosis and with soporifics. W. STRAUB. München. med. Wchnschr., 1913, lx, 1823.

Nitrous-oxide oxygen analgesia. M. SALZAR. Lancet-Clin., 1913, cx, 114.

The employment of local anæsthesia in surgical practice. A. OBERST. Ztschr. f. ärztl. Fortbild., 1913, x, 513.

Animal experiments on the toxicology of alypin. SCHRÖDER. Deutsche med. Wchnschr., 1913, xxxix, 1459.

Local anæsthesia in oto-rhino-laryngology. W. UFFENORDE. Ztschr. f. Ohrenh., 1913, lxviii, 293.

A modification of mandibular anæsthesia. H. TÜRKHEIM. Deutsche Monatschr. f. Zahnh., 1913, xxxi, 423.

Conduction anæsthesia of the lower jaw. P. GADD. Odontologie, 1913, xlix, 447.

Sacral anæsthesia. SCHLIMPERT. Deutsche Gesellschaft. f. Gynäk., Halle, 1913, May. [600]

New methods in spinal analgesia. T. TUFFIER. Tr. Internat. Cong. Med., Lond., 1913, Aug. [600]

General analgesia by cocaine anæsthesia of the lumbosacral route. LE FILLIATRE. Tr. Internat. Cong. Med., Lond., 1913, Aug. [600]

Paralysis of the phrenic nerve after plexus anæsthesia. F. BRUNNER. Zentralbl. f. Chir., 1913, xl, 1104. [600]

Anæsthesia with ethyl chloride given in small doses on compresses. VANVERTS. L'echo med. du Nord, Lille, 1913, xvii, No. 33.

"Narcosia," a new hamamelis local anæsthetic. GEMBICKI. Deutsche zahnärztl. Wchnschr., 1913, xvi, 521. [601]

Hedonal narcosis. J. P. LASTOTSCHKIN. Chirurgia, St. Petersb., 1913, xxxiv, 1.

A table for employment in intravenous hedonal narcosis. A. M. NIKOLSKI. Chirurgia, St. Petersb., 1913, xxxiv, 30.

Strengthening the effect of ordinary narcotics by the use of bromide salts. M. H. FLAMMER. Ztschr. f. d. ges. exp. Med., 1913, i, 575.

The benefits of double anæsthesia. JOHN W. SEYBOLD. Denver Med. Times, 1913, xxxiii, 44.

The value of anoci-association. J. H. CHALDECOTT and C. W. S. BRYAN. Lancet, Lond., 1913, clxxxv, 721.

Surgical Instruments and Apparatus

An apparatus (anæsthetometer) for measuring and mixing anæsthetics and other vapors and gases. KARL CONNELL. Surg., Gynec. & Obst., 1913, xvii, 245. [601]

An apparatus for producing narcosis by hyperpressure; a new critical discussion and a communication concerning a

new simplified apparatus. W. GERLACH. *Deutsche Ztschr. f. Chir.*, 1913, cxxiii, 205.

A new tongue and cheek holder. A. GUTTMANN. *Deutsche zahnärztl. Wchnschr.*, 1913, xvi, 617.

An improved audiometer. H. HAYS. *Laryngoscope*, 1913, xxiii, 864.

An endoscopic syringe. CHEVALIER JACKSON. *Laryngoscope*, 1913, xxiii, 863.

A coin-catcher for removing coins from the oesophagus. J. R. GILBERT. *J. Am. M. Ass.*, 1913, lxi, 491.

The respirator; an appliance for resuscitation by producing enforced respiration; report of 163 experiments. H. E. TOMPKINS. *N. Y. M. J.*, 1913, xcvi, 369.

Description of an abdominal, lumbo-ilio-sacral support and its uses, advantages and limitations. H. W. MARSHALL. *Boston M. & S. J.*, 1913, clxix, 275.

New instruments for the duodenum and the small intestine. MAX EINHORN. *Berl. klin. Wchnschr.*, 1913, l, 1344.

Stomach clamps. HERTLE. *Zentralbl. f. Chir.*, 1913, xl, No. 33.

An apparatus with pneumatically closed opening for use in colostomy. JOSEF WINKLER. *Wien. klin. Wchnschr.*, 1913, xxvi, 1365.

Use of electric compresses for heat in gynecology and abdominal surgery. RISS. *Marseille méd.*, 1913, l, No. 16.

Apparatus for transportation of patients with injuries of the legs. WEISSENSTEIN. *Mil.-ärzt.*, 1913, xlvii, 205.

The employment of spreading springs in the treatment of purulent processes. MAX TIEGEL. *Zentralbl. f. Chir.*, 1913, xl, 1137.

A new operating table. M. BORCHARDT. *Berl. klin. Wchnschr.*, 1913, l, 1441.

A pus receptacle with handle. MAX TIEGEL. *München. med. Wchnschr.*, 1913, lx, 1941.

An instrument for adjusting the clamps of v. Herff. LANGE. *Zentralbl. f. Gynäk.*, 1913, xxxvii, No. 34.

Care of surgical instruments. DUBREUIL. *J. de med. de Bordeaux*, 1913, lxxxiv, No. 33.

SURGERY OF THE HEAD AND NECK

Head

Congenital bilateral fistulae of the lower lip. MILLER KAHN. *Am. J. M. Sc.*, 1913, cxlvi, 223. [601]

Primary sarcoma of the lower lip. A. J. MARKLEY. *J. Am. M. Ass.*, 1913, lxi, 334.

Parotitis following operative interventions in the abdominal cavity, especially upon the female genitalia. VERNER VON HERZER. *Finska läk.-sällsk. handl.*, Helsingfors, 1913, lv, 52.

Primary and isolated actinomycosis of the salivary glands. GUSTAF SÖDERLUND. *Deutsche med. Wchnschr.*, 1913, xxxix, 1632.

Cysts of the maxillary sinus. COLLET. *Ann. d. mal. de l'oreille, du larynx, du nez et du pharynx*, Par., 1913, xxxix, No. 7.

Dental empyema of the maxillary sinus. PAUL ROSENSTEIN. *Deutsche Monatschr. f. Zahnh.*, 1913, xxxi, 406.

Accidents in lavages of the maxillary sinus. RÉTHI. *Ztschr. f. Laryngol., Rhinol. u. i. Grenzgeb.*, 1913, vi, 519.

The literature of cysts of the maxillary bones. GERBER. *Beitr. z. Anat., Physiol., Path. u. Therap. d. Ohrens, d. Nase, u. d. Halses*, 1913, vi, Nos. 4-6.

Osteoplastic repair of congenital and acquired defects of the lower maxillary bone. RUDOLF GÖBELL. *Deutsche Ztschr. f. Chir.*, 1913, cxxiii, 144.

A case of temporary resection of the superior maxillary bone for an ossifying chondroma of the nasopharynx. KOCHER and HORAND. *Lyon chir.*, 1913, x, No. 2.

The treatment of fractures of the mandible. F. COLEMAN. *Tr. Internat. Cong. Med.*, Lond., 1913, Aug. [602]

Suppuration of the frontal sinuses. VON LÄNG. *Beitr. z. klin. Chir.*, 1913, lxxxiv, 226. [604]

Celluloid plate used 16 years ago to replace defect in frontal bone. H. SCHLOFFER. *Prag. med. Wchnschr.*, 1913, xxxviii, 383.

On the treatment of fractures of the petrous portion of the temporal bone. H. NIMIER and A. NIMIER. *Rev. de chir.*, 1913, xlviii, 22. [604]

Operative treatment of wounds of the skull with blunt instruments. R. BRADE. *Deutsche mil.-ärztl. Ztschr.*, 1913, xlii, 641.

Findings in obscure head lesions. W. F. MANGES. *Tr. Am. Röntg. Ray Soc.*, Boston, 1913, Oct. [604]

Fractures of the skull. E. KILBOURNE TULLIDGE. *Hosp. Bull. Univ. Md.*, 1913, ix, 107.

Prognosis and treatment of compound fracture of the base of the skull. A. C. BURNHAM. *Boston M. & S. J.*, 1913, clxix, 270.

Operative treatment of fibromata of the base of the skull. KRASSINE. *Chirurgia, St. Petersburg*, 1913, xxxiii, No. 193.

Cystic fibrous otitis of the skull. FRANGENHEIM. *Zentralbl. f. Chir.*, 1913, xxxiv, 1345.

A case of hydrocephalus. J. SPEESE. *Arch. Pediatrics*, 1913, xxx, 600.

Traumatic epilepsy. MARCHAND. *Rev. de l. Hosp.*, 1913, vi, No. 6.

Traumatic epilepsy, and its surgical treatment. MATTHIAE. *Deutsche Ztschr. f. Chir.*, 1913, cxxiii, Nos. 5-6.

The question of surgical treatment of cortical, traumatic or non-traumatic, epilepsy. W. J. RASUMOWSKY. *Arch. f. klin. Chir.*, 1913, ci, 1075. [605]

The operative treatment of traumatic epilepsy. KOLACZEK. *Deutsche Ztschr. f. Nervenhe.*, 1913, lxvii-lxviii, Festschr. f. v. Strümpell, 312.

The operative treatment of epilepsy. RAUCH. *Beitr. z. klin. Chir.*, 1913, lxxxv, No. 3.

Surgical treatment of epilepsy. FRACASSI. *Rev. med. d. Rosario*, 1913, iii, No. 3.

Experiments on the cerebral cortex with relation to the production of cortical epilepsy (a) after the administration of hypnotics, (b) after the administration of bromides. G. BIKELES and L. ZBYSEWSKI. *Neurol. Zentralbl.*, 1913, xxxii, 1081.

The individual differences in the extent of the motor area of the cortex. JEANNOT ISRAELSOHN. *Arb. a. d. neurol. Inst. a. d. Wien. Univ.*, 1913, xx, 155.

Sarcomas of the cranial dura mater. DAMBRIN and NANTA. *Arch. med. de Toulouse*, 1913, xx, No. 14.

Hæmangioma of the meninges in vascular nævus of the face. OTTO HEBOLD. *Arch. f. Psychiatr. u. Nervenkrankh.*, 1913, li, 445.

Epidemic meningitis and meningo-bacterin. S. H. WADHAM. *Mil.-Surg.*, 1913, xxxiii, 130.

A case of occipital meningocele. NEGRI. *Clin. chir.*, Milano, 1913, xxi, No. 7.

Autoplastic fat transplantation for defects of the dura and the brain. E. REHN. Arch. f. klin. Chir., 1913, ci, 962. [605]

Disturbances of the gustatory sensation in lesions of the internal capsule and the optic thalamus. PAUL SCHILDER. Deutsche Ztschr. f. Nervenhe., 1913, xlvii-xlviii, Festschr. f. v. Strümpell, 472.

Traumatic intracranial effusions, both intra- and extradural. ROCHET and CHARBONNEL. Prov. med., Par., 1913, xxvi, No. 31.

A human being without a cerebrum. T. HOUGH. Va. M. Semi-Month., 1913, xviii, 239.

A human being without a cerebrum. L. EDINGER and B. FISCHER. Arch. f. d. ges. Physiol., 1913, clii, 535.

Air in the ventricles of the brain following a fracture of the skull; report of a case. W. H. LUCKETT. Surg., Gynec. & Obst., 1913, xvii, 237. [605]

Several instructive false diagnoses in cerebral tumors. EDUARD MÜLLER. Deutsche Ztschr. f. Nervenhe., 1913, xlvii-xlviii, Festschr. f. v. Strümpell, 388.

Increased pressure of the cerebro-spinal fluid in brain tumors. ANDRÉ THOMAS. Clinique, Par., 1913, viii, 514.

The treatment of tumors of the brain and the indications for operation. BRUNS. Tr. Internat. Cong. Med., Lond., 1913, Aug. [606]

Types of paralysis and functional cerebral foci. JOSEPH REICH. Deutsche Ztschr. f. Nervenhe., 1913, xli, 446.

Diagnosis and surgical treatment of diseases of the brain. BYCHOWSKI. Medycyna i Kron. lek., Warszawa, 1913, xlviii, Nos. 33-34.

Aneurisms of the cerebral arteries and their consequences. REINHARDT. Mitt. a. d. Grenzgeb. d. Med. u. Chir., 1913, xxvi, No. 3.

A case of polypus in the vermiform process. P. SSITKOWSKY. Med. Obsr., St. Petersburg, 1913, lxxx, 74.

The clinical value of palpation of the vermiform process. M. RJESAKOFF. Med. Obsr., St. Petersburg, 1913, lxxx, 61.

Surgery of tumors of the ponto-cerebellar angle. MARX. Mitt. a. d. Grenzgeb. d. Med. u. Chir., 1913, xxvi, No. 1.

Median compression of the cerebellum. GREGGIO. Clin. chir., Milano, 1913, xxi, No. 7.

Acromegaly. ADOLF REINHARDT, CREUTZFELDT and HANS GERHARD. Beitr. z. path. Anat. u. z. allg. Path., 1913, lvi, 465.

Acromegaly. A. LERI. Handb. d. Neurol., 1913, iv, 283. [606]

Experimental researches on the physiology of the hypophysis. HANS SCHLIMPERT. Monatschr. f. Geburtsh. u. Gynäk., 1913, xxxviii, 8.

Comparative anatomy and histology of the hypophysis cerebri. W. STENDELL. Arch. f. microscop. Anat., 1913, lxxxii, 289. [607]

Study of lesions of the hypophysis. RONCHETTI. Gior. d. r. Accad. di med. di Torino, 1913, lxxvi, Nos. 3-4.

Pharmacological investigations of the active principles of the hypophysis. H. FÜHNER. Ztschr. f. d. ges. exp. Med., 1913, i, 397. [607]

Paths of discharge from the hypophysis. HANS WASSING. Wien. klin. Wchnschr., 1913, xxvi, 1270.

The provenience of the blood-pressure increasing substance in the hypophysis. G. SCHICKELE. Ztschr. f. d. ges. exp. Med., 1913, i, 545.

Experimental compression of the hypophysis. A. AUSTONI. Policlin., Roma, sez. chir., 1913, xx, 159. [607]

Hypophyseal adiposity (Basophile adenoma of the hypophysis). THEODOR BAUER and HANS WASSING. Wien. klin. Wchnschr., 1913, xxvi, 1236.

The relation of the sexual glands to the hypophysis. BARNABO. Policlin., Roma, sez. chir., 1913, xx, No. 8.

A new method of operation on the hypophysis. PREY-

SING. Internat. Zentralbl. f. Laryngol., Rhinol. u. verw. Wiss., 1913, xxix, 401. [607]

Operations on the hypophysis by the nasal route. G. HOLMGREN. Hygiea, 1913, lxxv, 481. [608]

A method of fixation of the hypophysis and its adnexa in the fresh state. ERWIN THOMAS. Deutsche Ztschr. f. Nervenhe., 1913, xlvii-xlviii, Festschr. f. v. Strümpell, 772.

Radiology of the pituitary body in epilepsy and pituitary disorders. G. C. JOHNSON. Tr. Am. Röntg. Ray Soc., Boston, 1913, Oct. [608]

Clinical studies in pituitary irritation with report of a case. L. J. GENELLA. New Orleans M. & S. J., 1913, lxvi, 93.

Ocular manifestations of disease of the pituitary body. G. M. WALDECK. J. Mich. St. Med. Soc., 1913, xii, 417.

Neck

The avoidance of unsightly scar deformities in the operative treatment of cervical lymphadenitis. JAS. H. NICOLL. Glasgow M. J., 1913, lxxx, 81. [608]

Primary fusio-cellular sarcoma localized in the cervical lymphatic glands. PARREIRA. Med. contemp., Lisbon, 1913, xxxi, No. 33.

The excision of the groups of cervical lymph glands in cancers of the mouth and of the pharynx. M. H. MORESTIN. J. de chir., 1913, x, 657. [609]

Tumors of the carotid body with report of two cases. A. GRAHAM. Cleveland M. J., 1913, xii, 537. [615]

False branchiomas. MASSON. Presse méd., Par., 1913, xxi, No. 65.

The treatment of oedema fugax (Quincke). K. ALBRACHT. Deutsche Ztschr. f. Nervenhe., 1913, xlvii-xlviii, Festschr. f. v. Strümpell, 833.

Contribution to the surgery of the neck. Is unilateral resection of the internal jugular and pneumogastric harmless? P. GUIBAL. Rev. de chir., 1913, xlviii, 96. [615]

Thyroid. W. EDMUNDS. J. Pathol. & Bacteriol., 1913, xviii, No. 1. [616]

Pathological changes of the thyroid gland in syphilis. E. W. BUSCH. Dissertation, St. Petersburg, 1913. [616]

The influence of the normal and the pathologically changed thyroid gland upon the nervous system according to experimental investigations. WALTER. Allg. Ztschr. f. Psychiat., 1913, lxx, 849.

Acute thyroiditis as a complication of acute tonsillitis. CLEMENT F. THEISEN. Albany Med. Ann., 1913, xxxiv, 445.

Metastatic adenoma of the thyroid, simulating a tumor of the spinal cord with compression myelitis, and a method of removing bone marrow from deep-lying bones for diagnostic purposes. H. C. JACOBÆUS. Deutsche Ztschr. f. Nervenhe., 1913, xlix, 74.

An embryonic teratoma of the thyroid region. EHLERS. Beitr. z. path. Anat. u. z. allg. Path., 1913, lvii, No. 1.

Effect of thyroidectomy on thyroid affections. A. KRECKE. Deutsche Ztschr. f. Nervenhe., 1913, xlvii-xlviii, Festschr. f. v. Strümpell, 337. [616]

The therapy of hyperthyroidism. H. A. H. BOUMAN. J.-Lancet, 1913, xxxiii, 425.

Surgical treatment of hyperthyroidism. CHARLES NOOTNAGEL. J.-Lancet, 1913, xxxiii, 423.

Goiter. H. H. HELBING. Eclec. M. J., 1913, lxxiii, 390.

Goiter from the standpoint of the specialist. M. B. TINKER. Laryngoscope, 1913, xxiii, 854.

The clinical and pathological relationships of hyperplastic and non-hyperplastic goiter. H. S. PLUMMER. J. Am. M. Ass., 1913, lxi, 650.

Studies on endemic goiter. DIETERLE, HIRSCHFELD and KLINGER. München. med. Wchnschr., 1913, lx, No. 33.

Notes on the pathology of simple and exophthalmic goiter. L. B. WILSON. *Med. Rec.*, 1913, lxxxiv, 373. [617]
 Treatment of exophthalmic goiter by radiotherapy. BELOT. *Arch. d'electr. med., exp. et clin.*, 1913, xxi, No. 364.

The structure of congenital struma. N. KRASNOGORSKI. *Virchows Arch. f. path. Anat., etc.*, 1913, cxxiii, 152.

Further material toward a theory of struma and Basedow's disease. WELJAMINOFF. *Russk. Vrach.*, 1913, xii, 349.

Diagnostic and therapeutic notes on Basedow's disease. Based on observations of 100 cases. JULIUS HALLERVORDEN. *Therap. d. Gegenw.*, 1913, liv, 295.

Lesions of the thyroid in Basedow's disease. G. ROUSSY and J. CLUNET. *Rev. Neurol.*, 1913, xxi, 1. [617]

Psychoses in Basedow's disease. ERNST COLLA. *Allg. Ztschr. f. Psychiatr. u. psych.-gerichtl. Med.*, 1913, lxx, 525.

Thirty cases of incomplete Basedow's disease or vasomotor neurosis. L. ALQUIER. *Rev. Neurol.*, 1913, xxi, 795.

Treatment of Basedow's disease. O. GÜNZEL. *Klin. therap. Wchnschr.*, 1913, xx, 995.

Myxoedema. HANS EPPINGER. *Handb. d. Neurol., Spez. Neurol.*, 1913, iv.

Parathyroidin treatment of spasmophilia. OSWALD MEYER. *Therap. d. Gegenw.*, 1913, liv, 354.

SURGERY OF THE CHEST

Chest Wall and Breast

Carcinoma and tuberculosis of the same breast. EDUARD BUNDSCHUH. *Beitr. z. path. anat. u. z. allg. Path.*, 1913, lvii, 65.

The treatment of recurrence and metastases from carcinoma of the breast. G. E. PFAHLER. *Tr. Internat. Cong. Med.*, Lond., 1913, Aug. [618]

Suddenly developed bilateral cancer of the breast. MARQUIS. *Gaz. d. Hôp., Par.*, 1913, lxxxvi, No. 91.

Excessive epidermoid development of the cellular elements of a cancer of the breast. PIERRE NADAL. *Bull. et mém. Soc. anat. de Par.*, 1913, lxxxviii, 352.

Retrograde carcinomatous invasion into a lymph gland in a case of cancer of the breast. PIERRE NADAL. *Bull. et mém. Soc. anat. de Par.*, 1913, lxxxviii, 353.

A case of fibro-adenoma of the breast. MIKOULINA-IVANOVA. *Vrach. Gaz.*, 1913, vi, No. 31.

The necessity for operation in all tumors of the breast. H. A. MOFFAT. *S. African M. Rec.*, 1913, xi, 330.

The cystic disease of the mammary gland associated with a cholesteroline cyst. PIERRE NADAL. *Bull. et mém. Soc. anat. de Par.*, 1913, lxxxviii, 355.

A simplified method of treating purulent mastitis by negative suction. W. M. WOLKOWITSCH. *Russk. Vrach.*, St. Petersburg, 1913, xii, 1002.

Penetrating injuries of chest and abdomen. GULEKE. *Arch. f. klin. Chir.*, 1913, ci, 1030. [618]

The treatment of fractures of the clavicle. N. KAEFER. *München. med. Wchnschr.*, 1913, lx, 1599. [618]

Scaphoid scapula. DRÄSEKE. *Ztschr. f. d. Erforsch. u. Behandl. d. jugendl. Schwachsinn.*, 1913, vi, 468. [619]

The scaphoid form of the scapula. BRUCKNER. *Jahrb. f. Kinderheilk.*, 1913, lxxviii, 291.

1. Total extirpation of the scapula for sarcoma. 2. Plastic operation for sarcoma of the knee. HORAK. *Čas. lek. česk.*, 1913, lii, 1038.

Repair of large defects of the diaphragm, the thoracic wall and the pericardium by transplantation of flaps of fascia. ANSCHEN. *Zentralbl. d. Chir.*, 1913, xl, No. 22.

Collapse of the lung in treatment of tuberculosis. SPENGLER. *Cor.-Bl. f. Schweiz. Ärzte*, 1913, xliii, 1025.

Pulmonary tuberculosis and surgery. GORSE and DUPICH. *Rev. de chir., Par.*, 1913, xxxiii, No. 8.

Operative treatment of hæmoptysis caused by the disossification of the thoracic wall, which produced compression of the lung (thoracoplastic pleuro-pneumolysis). LISCHKIEWITSCH. *Beitr. z. klin. Chir.*, 1913, lxxxvi, No. 1.

Therapeutic pneumothorax. S. DAUS. *Ztschr. f. Tuberkul.*, 1913, xx, 383.

Artificial pneumothorax, used in the fourth month of

pregnancy. D. O. KUTHY and G. LOBMAYER. *Beitr. z. klin. d. Tuberkul.*, 1913, xxvii, 285.

A case of artificial pneumothorax in the treatment of pleurisy with effusion. R. M. ALEXANDER. *N. Y. M. J.*, 1913, xcvi, 426.

Interlobar pulsating empyema. E. LEVI. *Wien. klin. Wchnschr.*, 1913, xxvi, 1276.

Experimental researches on the significance of mediastinal rigidity ("Mediastinalstarre") and its artificial production. MENZEL. *Beitr. z. klin. Chir.*, 1913, lxxxvi, No. 1.

Chronic mediastinitis; its cause and treatment. C. LIAN. *Med. Press & Circ.*, 1913, xcvi, 143.

Syphilis of the mediastinum. N. FUSCHEFF. *Vrach. Gaz.*, St. Petersburg, 1913, xx, 987.

Malignant tumor of the mediastinum in an infant thirteen months old. KALLE and SALIN. *Arch. de méd. d. enfants, Par.*, 1913, xvi, No. 8.

A case of arrested development of the thymo-pharyngeal canals. KOURLOFF. *Vrach. Gaz.*, 1913, vi, No. 29.

The thymus gland. KARL BAASCH. *Deutsche med. Wchnschr.*, 1913, xxxix, 1455.

The physiology and pathology of the thymus gland. The significance of hyperplasia of its medullary tissues. GARHARD MEINHOLD. *Deutsche med. Wchnschr.*, 1913, xxxix, 1628.

A contribution to the symptomatology and therapy of thymus hypertrophy. BOISSONNAS. *Ztschr. f. Kinderheilk.*, 1913, vii, 472. [619]

Hypertrophy of the thymus in an infant two and one half years old. SOUTY. *Ann. d. mal. de l'oreille, du larynx, du nez et du pharynx, Par.*, 1913, xxxix, No. 7.

Trachea and Lungs

Report of one hundred tracheotomies. BERWALD. *Klin.-therap. Wchnschr.*, 1913, xx, 989.

The procedure in difficult removal of tracheotomy tube. BRÜGGEMANN. *Ztschr. f. Laryngol., Rhinol. u. i. Grenzgeb.*, 1913, vi, 502.

Tracheo-bronchoscopy and laryngoscopy with head suspended. ZIMNE. *Vrach. Gaz.*, 1913, vi, No. 28.

Bronchoscopic removal of a collar button after twenty-six years' sojourn in the lung. C. JACKSON. *Ann. Otol., Rhinol. & Laryngol.*, 1913, xxii, 360.

A new position for bronchoscopy and œsophagoscopy and its advantages over the classic position. J. MOURET. *Tr. Internat. Cong. Med.*, Lond., 1913, Aug. [619]

History of a broncholith, bronchial calculus or lung stone. WALTER F. CHAPPELL. *Med. Rec.*, 1913, lxxiv, 294.

Tuberculosis of the tracheobronchial glands and its surgical treatment. BETKE. *Beitr. z. klin. Chir.*, 1913, lxxxv, No. 3.

Bronchiogenic carcinoma. H. E. LORENZ. *Beitr. z. klin. Chir.*, 1913, lxxxv, 599. [620]

"Cylindroma" of the upper respiratory passages. WILLY PFEIFFER. *Arch. f. Laryngol. u. Rhinol.*, 1913, xxvii, 156.

The spontaneous healing of pulmonary wounds. MAX TIEGEL. *Arch. f. klin. Chir.*, 1913, ci, 921.

Foreign bodies in the lungs; a report of two cases. H. R. M. LANDIS. *Penn. M. J.*, 1913, xvi, 870.

Two cases of rupture of the lung without fracture of the rib. WIDERÖE. *Norsk. Mag. f. Lägevidensk.*, Christiania, 1913, lxxiv, No. 9.

A case of saccharomycete infection of the lungs. W. WOVSCHEIN. *Med. Rec.*, 1913, lxxxiv, 388.

Artificial respiration. GÖRAN LILJESTRAND. *Mitt. a. d. Grenzgeb. d. Med. u. Chir.*, 1913, xxvi, 470.

Pituitrin in operative and spontaneous hæmorrhage of the respiratory passages. S. CITELLI. *Tr. Internat. Cong. Med.*, Lond., 1913, Aug. [620]

Heart and Vascular System

Injuries to the heart. LEOTTA. *Policlin.*, Roma, sez. chir., 1913, xx, No. 8.

Diagnosis of injuries of the heart. HÄCKER. *Beitr. z. klin. Chir.*, 1913, lxxxvi, No. 1.

A case of prolonged cessation of heart action resulting from a needle injury to the heart. LEPORSKY. *Russk. Vrach.*, 1913, xii, 118. [620]

Needle in the heart fifteen months; death; autopsy. W. P. NORTHRUP. *Am. J. Dis. Children*, 1913, vi, 87.

Two operations for wounds of the heart; one death; one recovery. CERNÉ. *Normandie med.*, 1913, xxix, No. 15.

Primary tumors of valves of the heart. G. DEAN and A. W. FALCONER. *J. Pathol. & Bacteriol.*, 1913, xviii, No. 1. [621]

Paroxysmal tachycardia in surgery. KAUSCH. *Verhandl. d. Gesellsch. deutscher Naturforsch. u. Ärzte*, 1913, ii, part 2, 110.

Pericardiolysis in a certain affection of the heart or supracardiac thoracotomy. H. DELAGENIÈRE. *Arch. prov. de Chir.*, 1913, xxii, 317. [621]

Further experimental studies on resorption in the region of the pericardium. GORINSTEIN. *Beitr. z. klin. Chir.*, 1913, lxxxvi, No. 1.

Absorption through the pericardium. C. L. GORINSTEIN. *Beitr. z. klin. Chir.*, 1913, lxxxvi, 229.

Caseous pericarditis and accident. AUERBACH. *München. med. Wchnschr.*, 1913, lx, No. 33.

Pharynx and Œsophagus

Congenital occlusions of the œsophagus and lesser bowel. G. H. EDINGTON. *Glasgow M. J.*, 1913, lxxx, 90.

False teeth arrested in the œsophagus for eight days. KELBLING. *Med. Klin.*, Berl., 1913, ix, No. 32.

A case of stenosis of the œsophagus and pylorus from ingestion of a caustic liquid. CERVERA Y RUIZ and LUIS Y YAGUE. *Rev. iber.-am. de cien. med.*, Madrid, 1913, xxx, No. 107.

Congenital atresia of the œsophagus; gastrotomy. STEINERT. *Prag. med. Wchnschr.*, 1913, xxxviii, No. 32.

Means of facilitating alimentation in carcinoma of the œsophagus. W. KRIENITZ. *Deutsche med. Wchnschr.*, 1913, xxxix, 1200.

The surgical treatment of carcinoma of the œsophagus. WILLY MEYER. *München. med. Wchnschr.*, 1913, lx, 1316.

Cancer of the œsophagus. MELLO. *Med. contemp.*, Lisbon, 1913, xxxi, No. 32.

Plastic surgery of the œsophagus. HALPERN. *Chirurgia*, St. Petersburg, 1913, xxxiii, No. 194.

Miscellaneous

Thoracic wounds caused by fire-arms. HUGUIER. *Paris chir.*, 1913, v, No. 5.

A case of compression of the thorax resulting in hæmorrhages due to congestion. ZIMMERMAN. *Beitr. z. klin. Chir.*, 1913, lxxxv, No. 3.

SURGERY OF THE ABDOMEN

Abdominal Wall and Peritoneum

Pfannenstiel's transverse incision. GODART. *Policlin.*, Brussels, 1913, xxii, No. 15.

Contributions on the subject of abdominal drainage. N. N. PETROFF. *Chir. arch. Veliaminova*, 1913, xxix, 195. [622]

A case of penetrating wound of the abdomen, with remarks on prophylaxis and treatment of peritonitis. F. WEBER. *München. med. Wchnschr.*, 1913, lx, 1772.

A tumor containing smooth muscle fibres discharged spontaneously through a laparotomy scar. IMBERT and MOIROUD. *Marseille méd.*, 1913, l, No. 16.

Paravesical chronically inflamed tumors of the abdominal wall. A. HOCK. *Ztschr. f. urol. Chir.*, 1913, i, 453.

Congenital defect of abdominal muscles, with anomaly of urinary apparatus. LEWIS THATCHER. *Edinb. M. J.*, 1913, xi, 127.

Rupture of the rectus muscles of the abdomen during gymnastics. ROMANTZEFF. *Vofenno-med. J.*, St. Petersburg, 1913, ccxxxvii, No. 4.

A case of echinococcus of the rectus muscle of the abdomen. FIRFAROFF. *Vrach. Gaz.*, 1913, vi, No. 23.

Subphrenic abscess. LEDDERHOSE. *Deutsche med. Wchnschr.*, 1913, xxxix, No. 31.

Pathogenesis of some forms of post-operative subphrenic abscess. FASANO. *Gazz. d. Osp. e d. Clin.*, Milano, 1913, xxxiv, No. 91.

Retroperitoneal sarcoma. KRON. *Chirurgia*, St. Petersburg, 1913, xxxiii, No. 194.

Formation of retroperitoneal lipomata, with special consideration of lipomata of the mesentery. EBNER. *Beitr. z. klin. Chir.*, 1913, lxxxvi, No. 1.

Gauze or rubber-tube drainage for the peritoneal cavity. J. Mo. St. M. Ass., 1913, x, 57.

Antiseptic tampon in peritonitis. CREDÉ. *Zentralbl. f. Chir.*, 1913, xl, 1373.

Acute progressive peritonitis. FISCHER. *Beitr. z. klin. Chir.*, 1913, lxxxv, No. 3.

Tetany in perforating peritonitis. HOLLERDORF. *Deutsche med. Wchnschr.*, 1913, xxxix, No. 31.

Biliary peritonitis. ROBERT VOGEL. *Wien. klin. Wchnschr.*, 1913, xxvi, 1153.

Free suppurative peritonitis due to pyosalpinx. JASPER HALPENNY. *Canad. Med. Ass. J.*, 1913, ii, 679.

Intraperitoneal employment of collargol in diffuse purulent peritonitis. R. JELKE. München. med. Wchnschr., 1913, lx, 1828.

Happy outcome of a case of tubercular peritonitis. GARRIGA. Rev. de Cien. med. de Barcelona, 1913, xxxix, No. 7.

A case of tubercular peritonitis cured at Lourdes. DAVID. J. d. sc. méd. de Lille, 1913, xxxvi, No. 32.

The treatment of ascitic tuberculous peritonitis (laparotomy and lavage with oxygen-impregnated water). GUACCERO. Clin. chir., Milano, 1913, xxi, No. 7.

The operative treatment of peritoneal and genital tuberculosis. O. SCHMIDT. Ztschr. f. Geburtsh. u. Gynäk., 1913, lxxiii, 404.

Pseudomyxoma of the peritoneum of appendicular origin. DELETTREX. Rev. de gynéc. et de chir. abdom., 1913, xxi, No. 1.

Atmospheric air in the abdomen following laparotomies. MAX COHN. Berl. klin. Wchnschr., 1913, l, 1352.

Abdominal adhesions. J. T. BURRUS. Va. Med. Semi-Month., 1913, xviii, 218.

Casuistics of rare form of inguinal hernia. CEREPNINE. Chirurgia, St. Petersburg., 1913, xxxiii, No. 194.

Inguinal hernias of the female genitalia, herniary adnexitis. DANIEL. Beitr. z. Geburtsh. u. Gynäk., 1913, xviii, No. 3.

Pathogenesis of encysted hernia and encysted communicating hernia. SULTAN and KURTZHALSS. Beitr. z. path. Anat. u. z. allg. Path., 1913, lvii, No. 1.

Epigastric hernia. DELBET. J. d. Prat., Par., 1913, xxvii, No. 34.

Epigastric hernia of the stomach. MANTELLI. Gior. d. r. Accad. di Med. di Torino, 1913, lxxvi, No. 3-4.

Painful epigastric hernia as a symptom of gastric ulcer. ALESSANDRINI. Policlin., Roma, 1913, xx, No. 31.

Heo-appendicular hernia of the appendix. L. W. ALLEN. Surg., Gynec. & Obst., 1913, xvii, 191. [622]

Two cases of incarcerated internal hernia in the region of the bladder. TRNKA. Čas. lek. česk., 1913, lii, 873.

Retrograde incarceration of the intestine in hernias. VON WISTINGHAUSEN. Deutsche Ztschr. f. Chir., 1913, cxvii, 212. [622]

The reduction of hernia. F. G. GALE. Mass. M. J., 1913, No. 8, 295.

Local anæsthesia in the radical cure of hernia. T. K. OATES. W. Va. M. J., 1913, viii, 51.

Radical cure of hernia by buried sutures of metallic thread. ROUX DE BRIGNOLLES and WEILL. Marseille méd., 1913, l, No. 16.

Importance of early operation for the radical cure of hernia. H. W. AUSTIN. N. Y. M. J., 1913, xcvi, 319.

A new operation for the cure of indirect inguinal hernia. U. C. BATES. Northwest Med., 1913, v, 211.

Some reasons for advising no delay in operating all forms of hernia. J. FRANKEL. N. Y. M. J., 1913, xcvi, 378.

The radical operation of inguinal hernia. H. DRESSMANN. Verhandl. d. Gesellsch. deutsche Naturforsch. u. Ärzte, 1913, ii, part 2, 150.

Technique of radical operation for inguinal hernia. KLEINSCHMIDT. München. med. Wchnschr., 1913, lx, 1920.

An improvement upon the Lotheisen-Föderl radical operation in crural hernias by the employment of free aponeurotic grafts. GÖBEL. Zentralbl. f. Chir., 1913, xl, No. 32.

Plastic operation to close defect in inguinal hernia. E. POLYA. Virchow's Arch. f. path. Anat., etc., 1913, ccxiii, 504.

Prolapse of omentum and stomach caused by a punctured wound which penetrated the thoracic and abdominal cavities. ALFRED KIRSCHNER. Dissertation, Königsberg, 1913.

Primary hydatid cyst of the great omentum. FERRER. Presse med., Par., 1913, xxi, No. 64.

Abscess of the omental sac following necrosis of the pancreas. BITTORF. Mitt. a. d. Grenzgeb. d. Med. u. Chir., 1913, xxvi, No. 1.

Tumor of the omentum with twist of pedicle, giving symptoms of acute appendicitis. G. LEGIARDI-LAURA. Med. Rec., 1913, lxxiv, 205.

A case of thrombosis of the mesentery. DROUIN and PARCELIER. J. de Med. de Bordeaux, 1913, lxxxiv, No. 33.

Thrombosis of the mesentery. E. LAPLACE. Tr. Internat. Cong. Med., Lond., 1913, Aug. [623]

Dermoid cyst of the mesentery. CASTELLO. Rev. de Med. y Cir., Habana, 1913, xviii, No. 11.

Gastro-Intestinal Tract

Tests for secretion and motility of the stomach. J. SCHUTZ. Wien. med. Wchnschr., 1913, lxiii, 927.

Organacidia gastrica. MARK I. KNAPP. Med. Council, 1913, xviii, 293.

The relation of the röntgen picture of the human stomach to its anatomical structure. Contribution to the anatomy and physiology of the stomach. GÖSTA FORSELL. Arch. u. Atlas d. norm. u. path. Anat. in typischen Röntgenbildern, Hamburg, 1913, xii.

Present status of radiographic examination of stomach and intestines. HOLZKNECHT. Arch. d'electr. med., exp. et clin., 1913, xxi, No. 364.

Recent results obtained with radiology of the stomach. HÜRTER. Beitr. z. klin. Med., 1913, ix, 177.

The value of X-ray pictures in the air-distended stomach as a means of checking the bismuth picture. W. RÖPKE. Verhandl. d. Gesellsch. deutscher Naturforsch. u. Ärzte, 1913, ii, part 2, 190.

A method of obtaining a radiograph of the stomach at any particular phase of its contraction. C. THURSTAN HOLLAND. Arch. Röntg. Ray, 1913, xviii, 98. [623]

The positive value of the röntgen method in the diagnosis of gastric and duodenal lesions. A. W. GEORGE. Tr. Am. Röntg. Ray Soc., Boston, 1913, Oct. [623]

Study of the mechanism of the stomach after gastroenterostomy by means of the X-ray. JOHN H. OUTLAND, E. H. SKINNER and LOGAN CLENDENING. Surg., Gynec. & Obst., 1913, xvii, 175. [624]

Mechanism of stomach and gall-bladder. HOHLWEG. Med. Klin., Berl., 1913, ix, 1420.

The metabolism of creatin and creatinin in severe lesions of the stomach. LAURA ORIOLI. Internat. Beitr. z. Path. u. Therap. d. Ernährungsstör., 1913, iv, 421.

Diagnosis and differential diagnosis of gastro-duodenal lesions. L. G. COLE. Tr. Am. Röntg. Ray Soc., Boston, 1913, Oct. [624]

A case of acute dilatation of the stomach complicating pneumonia. EDWARD H. GOODMAN. N. Y. M. J., 1913, xcvi, 271.

The rôle of gastric and intestinal stasis in some cases of epilepsy. HALE POWERS. Boston M. & S. J., 1913, clxix, 189.

Indications afforded by X-rays for and against operations in diseases of the stomach and results of such operations. A. H. PIRIE. Tr. Am. Röntg. Ray Soc., Boston, 1913, Oct. [625]

Diagnosis of gastric ulcers suddenly penetrating into the free abdominal cavity. HANS RYSER. Cor.-Bl. f. schweiz. Ärzte, 1913, xliii, 961.

Pathology and treatment of ulcer of the stomach; diagnosis and treatment of chronic juxta-pyloric ulcer. KEMP. Ugesk. f. Læger, Kjøbenhavn, 1913, lxxv, Nos. 36-37.

Two cases of perforation of gastric ulcer. TIMBAL and LAVAU. Toulouse méd., 1913, xv, No. 15.

The digestion of living tissue in the stomach, and a study of the pathogenesis of round ulcer of the stomach. KAWAMURA. Mitt. a. d. Grenzgeb. d. Med. u. Chir., 1913, xxvi, No. 3.

Chronic juxta-pyloric ulcer of the stomach. FABER. Med. Klin., Berl., 1913, No. 34.

The production of ulcer of the stomach in the rat. CHARLES SINGER. Lancet, Lond., 1913, clxxxv, 279.

Late ulcer of the stomach. RISPAL and TIMBAL. Toulouse méd., 1913, xv, No. 14.

Experimental employment of X-ray treatment in gastric ulcer. EUGEN KODON. Fortschr. a. d. Geb. d. Röntgenstr., 1913, xx, 505.

Experiences in the surgical treatment of benign affections of the stomach and duodenum. A. HENLE. Verhandl. d. Gesellsch. deutscher Naturf. u. Ärzte, 1913, ii, 144. [625]

Diagnosis of gastric cancer. A. R. LENSMA. Northwest Med., 1913, v, 217.

Primary myosarcoma of the stomach and the diagnostic difficulties in tumors of the gastric wall. AMELUNG. Beitr. z. klin. Chir., 1913, lxxvi, No. 1.

Carcinoma of the stomach from a surgical standpoint. R. E. VENNING. W. Va. M. J., 1913, viii, 37.

Operative treatment of cancer of the stomach. WILLIAM J. MAYO. J. Am. M. Ass., 1913, lxi, 540.

The treatment of hæmatemesis. OTTO GRÜNBAUM. Practitioner, Lond., 1913, xci, 157.

Gastroscopy and its clinical value. LICHTENDORF. Russk. Vrach, St. Petersburg, 1913, xii, No. 32.

Some phases of surgery of the stomach. GEORGE WOOLSEY. N. Y. St. J. Med., 1913, xiii, 417.

Surgical indications of certain gastro-intestinal symptoms. J. DOUGLAS. N. Y. M. J., 1913, xcvi, 359.

Local anæsthesia in gastric surgery. COMBIER. Bourgogne méd., Dijon, 1913, xxi, No. 7.

Partial gastrectomy. S. W. F. RICHARDSON. So. African M. Rec., 1913, xi, 344.

Changes in the digestive process after gastro-duodenotomy, gastrojejunostomy, and total gastrectomy. DAGAEW. Mitt. a. d. Grenzgeb. d. Med. u. Chir., 1913, xxvi, No. 1.

Congenital stenosis of the pylorus. A. STRAUCH. Med. Rec., 1913, lxxxiv, 386.

Congenital hypertrophic stenosis of the pylorus. C. G. MIXTER. Boston M. & S. J., 1913, clxix, 309.

Stenosis of the pylorus and the formation of a ligamentum suspensorium ventriculi by transplantation of free aponeurotic fascia. RUDOLF GÖBEL. Zentralbl. f. Chir., 1913, xl, 1332.

Congenital pyloric stenosis, with report of case. L. S. BOOKER. Va. M. Semi-Month., 1913, xviii, 243.

The technique of exclusion of the pylorus. POLYA. Zentralbl. f. Chir., xl, No. 34.

The technique of exclusion of the pylorus. ADOLPH HOFFMANN. Zentralbl. f. Chir., 1913, xl, 1331.

Technique of X-ray examination of the duodenum. O. DAVID. Zentralbl. f. inn. Med., 1913, xxxiv, 531.

Diagnostic value of radiology in diseases of the duodenum, based on 31 operative cases. MÜLLER. Mitt. a. d. Grenzgeb. d. Med. u. Chir., 1913, xxvi, No. 1.

Permanent alimentation through a duodenal sound. PAUL LAZARUS. Berl. klin. Wchnschr., 1913, l, 1391.

Indications for duodenal alimentation. M. EINHORN. Deutsche med. Wchnschr., 1913, xxxix, 1404. [626]

Symptoms, diagnosis and treatment of duodenal ulcer. ROERSCH. Scalp. et Liege med., 1913, lxvi, No. 7.

Duodenal ulcer. ROSENGART. München. med. Wchnschr., 1913, lx, 1737.

Duodenal ulcer of nervous origin. WESTPHAL and KATSCH. Mitt. a. d. Grenzgeb. d. Med. u. Chir., 1913, xxvi, No. 3.

Duodenal ulcer with illustrative cases. L. H. HEMPELMANN. Interst. M. J., 1913, xx, 726.

Further experiences with duodenal ulcer. M. EINHORN. Med. Rec., 1913, lxxxiv, 369.

Hæmorrhagic form of duodenal ulcer. CASTAIGNE. J. de Med. et de Chir., Montreal, 1913, viii, No. 6.

Duodenal treatment. ROSENBERGER. Med. Klin., Berl., 1913, ix, No. 31.

Jejunostomy. PAUCHET. Clinique, Par., 1913, vii, No. 34.

The physiology of gastro-jejunostomy. H. J. PATERSON. Tr. Internat. Cong. Med., Lond., 1913, Aug. [626]

Intestinal obstruction. JOHN A. HARTWELL. J. Exp. Med., 1913, xviii, 113.

Intestinal invagination. DOBRUCKI. Prezgl. chir. i ginéc., 1913, ix, 73.

A case of volvulus of the small intestine complicating general peritonitis; recovery. C. WILLETT CUNNINGTON. Lancet, Lond., 1913, clxxxv, 387.

The diagnosis of intussusception. I. M. SNOW and M. CLINTON. Am. J. Dis. Children, 1913, vi, 93.

Intussusception of the stomach and duodenum due to a gastric polypus. H. WADE. Surg., Gynec. & Obst., 1913, xvii, 184.

Acute intussusception. H. LETT. Clin. J., 1913, xlii, 312.

Congenital multiple atresia of the small intestine. PETRIVASKY. Čas. lek. česk., 1913, lii, 871.

Intestinal occlusion and the value of radiology in the diagnosis of intestinal stenosis. MATHIEU. J. d. Prat., Par., 1913, xxvii, No. 33.

A case of intestinal occlusion with congenital retro-position of the large intestine. RÖVSING. Hosp.-Tid., Kjøbenhavn, 1913, lvi, No. 31.

Fœtal peritoneal folds and their relation to post-natal chronic and acute occlusions of the large and small intestine. J. R. EASTMAN. J. Am. M. Ass., 1913, lxi, 625. [627]

Treatment of ileus caused by post-operative adhesions. ZAHRADNICKY. Wien. med. Wchnschr., 1913, lxii, No. 32.

Malpositions of the abdominal viscera in intestinal stasis. D. Y. KEITH. Ky. M. J., 1913, xi, 638.

Chronic intestinal stasis. L. MILLER KAHN. N. Y. M. J., 1913, xcvi, 274.

Surgical aspects of intestinal stasis from an anatomic point of view. J. E. SUMMERS. J. Am. M. Ass., 1913, lxi, 639. [628]

Diffuse adenomatous intestinal polyposis. SCAGLIOSI. Deutsche med. Wchnschr., 1913, xxxix, No. 31.

Intestinal polyposis of intestinal polyadenomatosis. BOHAY. Jahrb. f. Kinderh. u. phys. Erzieh., 1913, lxxviii, No. 2.

A case of pneumatosis cystoides intestinorum. MIASNIKOFF. Vrach. Gaz., 1913, vi, No. 8.

The surgical and pathological importance of certain intestinal parasites. GRÜNBAUM. Dissertation, Heidelberg, 1913.

Mucous cyst of the cæcum in an infant 10 weeks old, producing obstruction of the ileocecal valve and symptoms simulating intussusception. A. D. BLACKADER. Am. J. Dis. Children, 1913, vi, 99.

Lipoma of the cæcum causing an invagination; laparotomy, disinvagination, removal of the tumor; recovery. MARIANO CICALO. Clin. chir., Milano, 1913, xxi, No. 7.

Hypertrophic ileocecal tuberculosis in a patient with pulmonary tuberculosis. SANTY and DURAND. Lyon méd., Lyon, 1913, cxxi, No. 31.

Pinching the appendix in the diagnosis of chronic appendicitis. ANTHONY BASSLER. *Am. J. M. Sc.*, 1913, cxlvi, 204.

Diagnosis of atonic condition of the appendix. HEINRICH STERN. *Deutsche med. Wchnschr.*, 1913, xxxix, 1305.

Diagnosis of important pathological changes associated with inflammation of vermiform appendix for treatment. WALTER GRIESS. *Lancet-Clin.*, 1913, cx, 174.

An appendix free in the abdominal cavity without suppurative peritonitis. J. WAGNER. *Med. Rec.*, 1913, lxxxiv, 339.

Inflammatory diverticula of the appendix. TICHOMIROFF. *Vrach. Gaz.*, St. Petersburg, 1913, xx, 650.

The appendix and some of its diseases. H. H. HIESCHER. *N. Y. M. J.*, 1913, xcvi, 373.

The pathogenesis of so-called "chronic inflammation of the appendix." DOBBERTIN. *Deutsche med. Wchnschr.*, 1913, xxxix, 1549.

Present status of blood examination in appendicitis and progressive appendicular peritonitis. SCHULTZE. *Mitt. a. d. Grenzgeb. d. Med. u. Chir.*, 1913, xxvi, No. 1.

Traumatic appendicitis. SCHWABE. *Ztschr. f. Versicherungsmed.*, 1913, vi, 225.

Chronic appendicitis in its relation to hyperacidity of the gastric juice. H. ILLOWAY. *N. Y. M. J.*, 1913, xcvi, 224.

Faulty circulation of the blood in Arneth's apparatus in chronic appendicitis. SAMOILLO. *Chirurgia, St. Petersburg*, 1913, xxxiii, No. 194.

Appendicitis in war. YERSIN. *Rev. suisse de méd.*, 1913, xiii, No. 22.

Appendicitis complicated by abscess of the liver. LASTOTCHKINE. *Vrach. Gaz.*, 1913, vi, No. 13.

Pseudomyxomatous cyst of the appendix. HAMMESFAHR. *Deutsche med. Wchnschr.*, 1913, xxxix, No. 31.

Dermoid cysts developed between the leaves of the meso-appendix; their differential diagnostic points from appendiceal tumors. WILLEMS. *Beitr. z. klin. Chir.*, 1913, lxxxvi, No. 1.

Reply to Koffman's views on extirpation of the appendix. E. SONNENBURG. *Zentralbl. f. Chir.*, 1913, xl, 1364.

Treatment and pathology of appendicitis. BENJAMIN S. PURSE. *Med. Rec.*, 1913, lxxxiv, 296.

When to operate in acute appendicitis. C. M. SWALE. *Iowa M. J.*, 1913, xx, 69.

Post-operative treatment in appendix operations. SORGE. *Berl. klin. Wchnschr.*, 1913, l, No. 32.

Pathology of the large intestine; diverticulum. PAUCHET. *Clinique, Par.*, 1913, viii, No. 31.

Volvulus of the large intestine. ED. BUNDSCHUH. *Beitr. z. klin. Chir.*, 1913, lxxxv, 58.

The operative treatment of malignant disease of the large intestine, excluding the rectum. W. KÖRTE. *Tr. Internat. Cong. Med.*, Lond., 1913, Aug. [628]

Deposits of lamellæ in the region of the proximal segment of the large intestine as an anatomical formation (ligamentum varioforme). REZANOFF. *Chirurgia, St. Petersburg*, 1913, xxxiii, No. 194.

Surgery of the large intestine with the exception of the rectum. B. K. FINKELSTEIN. *Arch. f. klin. Chir.*, 1913, ci, 936.

X-ray observations on colonic peristalsis and antiperistalsis with special reference to the function of the ileocolic valve. J. T. CASE. *Tr. Internat. Cong. Med.*, Lond., 1913, Aug. [628]

Ulcerative colitis. ANTHONY BASSLER. *Interst. M. J.*, 1913, xx, 707.

Ulcerative colitis. JULIAN KRETSCHMER. *Zentralbl. f. d. Grenzgeb. d. Med. u. d. Chir.*, 1913, xvii, 66.

A brief survey of the prognosis and treatment of con-

genital and acquired dilatation of the colon. LEWIS J. FRIEDMAN. *Am. J. Surg.*, 1913, xxvii, 291.

A case of Hirschsprung's disease. H. C. VAN DEN VRIJHOEF. *Wien. klin. Wchnschr.*, 1913, xxvi, 1309.

The diagnosis of Hirschsprung's disease. FRANK. *Mitt. a. d. Grenzgeb. d. Med. u. Chir.*, 1913, xxvi, No. 1.

The ultimate nervous results of acute angulation of the sigmoid and the consequent faecal stasis. W. H. AXTELL. *Northwest Med.*, 1913, v, 215.

Surgical treatment of chronic constipation. A. E. HERTZLER. *J. Mo. St. M. Ass.*, 1913, x, 48.

Experimental transplantation of intestine after extensive excision of the sigmoid. J. SHELTON HORSLEY. *J. Am. M. Ass.*, 1913, lxi, 544.

Mobilization of the base of the pelvic mesocolon to re-establish direct continuity of the intestine in resection of the iliac colon and the terminal portion of the descending colon. VIGNOLO. *Rif. med.*, Naples, 1913, xxix, No. 33.

Polyposis of the rectum. BORMAN. *Vrach. Gaz.*, 1913, vi, No. 20.

Continence of the bowel after radical operation for carcinoma of the rectum. HERBERT KÖRBL. *Arch. f. klin. Chir.*, 1913, ci, 449. [629]

The treatment of prolapse of the rectum in children. FELIX PIELSTICKER. *Monatschr. f. Kinderh.*, 1913, xii, 111.

Amputation of the rectum with exclusion of the pelvic colon. G. KELLING. *Zentralbl. f. Chir.*, 1913, xl, 947.

Permanent artificial anus. CARL. *Beitr. z. klin. Chir.*, 1913, lxxxvi, No. 1.

Sphincteric atrophy; causes, consequence and treatment. RALPH W. JACKSON. *Boston M. & S. J.*, 1912, clxix, 221.

Topography and function of the normal digestive organs studied with the aid of radiography; localization of foreign bodies in their interior. CATCHEVITCH. *Srpski arh. za celok. lek.*, Beograd, 1913, xix, No. 233.

Results obtained by deep topographic palpation of the digestive canal. HAUSMANN. *Berl. klin. Wchnschr.*, 1913, l, No. 32.

Experimental radiological studies on the physiology and pathology of the alimentary tract. R. LENK and F. EISLER. *München med. Wchnschr.*, 1913, lx, 1031. [630]

The technique of röntgen-ray examination of the gastrointestinal tract and the interpretation of screen and plate findings. R. D. CARMAN. *J. Am. M. Ass.*, 1913, lxi, 321. [630]

Syphilis of the gastro-intestinal tract. J. G. WELLS. *Post-Graduate*, 1913, xxviii, 715.

Recent treatment of gastro-intestinal stasis due to ptosis of the alimentary canal. T. J. B. KELLY. *Australas. M. Gaz.*, 1913, xxxiv, 172.

Liver, Pancreas, and Spleen

Ptosis of the liver and X-rays. GOBEAUX. *Ann. de la Policlin. centr. de Brux.*, 1913, xiii, No. 6.

Cirrhosis of the liver. J. M. WHYTE. *Clin. J.*, 1913, xlii, 317.

Etiological differential diagnosis and interpretation of cirrhoses of the liver. CAILLIAU. *Gaz. d. hôp.*, Par., 1913, lxxxvi, No. 94.

Operative method of treatment of ascites in cirrhosis of the liver. MANTELLI. *Gior. d. r. Accad. di Med. di Torino*, 1913, lxxvi, Nos. 3-4.

Diseases of the liver and gall passages; a contribution to tropical surgery. R. LESK. *Geneesk. Tijdschr. voor Ned. Ind.*, 1913, liii, 356.

Diagnosis of abscess of the liver. CORDARELLI. *Boll. d. Clin.*, xxx, No. 7.

Traumatic abscess of the liver. D'AGOSTINO. *Rif. med.*, Naples, 1913, xxix, No. 33.

A case of abscess of the liver in appendicitis. BARADOUINE. *Chirurgia*, St. Petersburg, 1913, xxxiii, No. 194.

Abscess of the liver after scarlet fever in child eight years old. MOURAVIEFF. *Chirurgia*, St. Petersburg, 1913, xxxiii, No. 194.

Treatment of abscess of the liver. PLICQUE. *Bull. méd.*, Par., 1913, xxvii, No. 61.

Hydatid cyst of the liver. W. M. SOWERS. *Va. M. Semi-Month.*, 1913, xviii, 241.

Multiple unilocular echinococcal cysts of the liver and spleen. VICHNEVSKY. *Sibirsk. Vrach. Gaz.*, 1913, vi, No. 30.

Spontaneous suppuration of echinococci of the liver. RITTERSHAUS. *Beitr. z. klin. Chir.*, 1913, lxxxv, 641.

Early recognition of surgical lesions of the liver. C. R. OGDEN. *W. Va. M. J.*, 1913, viii, 46.

Applicability of fascia lata in resections of the liver. B. CHESIN. *Zentralbl. f. Chir.*, 1913, xl, 1173.

Cholelithiasis. A. AOYAMA. *Beitr. z. path. Anat. u. z. allg. Path.*, 1913, lvii, 168.

Cholelithiasis associated with duodenal ulcer and pancreatic abscess. FRANZ VON FINK. *Prag. med. Wchnschr.*, 1913, xxxviii, 396.

Cholelithiasis with a short review of one hundred necropsies. W. OPHULS. *Cal. St. J. M.*, 1913, xi, 306.

Gall-stones. F. J. STEWARD. *Clin. J.*, 1913, xlii, 305.

The diatetic treatment of gall-stones. SALOMON. *Med. Klin.*, Berl., 1913, ix, 1317.

Management after gall-stone operations. WELLER VAN HOOK. *Iowa M. J.*, 1913, xx, 79.

The influence on gastric secretion of aseptic foreign bodies in the gall-bladder. O. H. PERRY PEPPER. *Am. J. M. Sc.*, 1913, cxlvi, 220.

Gall-tract disease; some clinical features frequently overlooked in its diagnosis. C. M. COOPER. *Cal. St. J. M.*, 1913, xi, 301.

The symptomatology of gall-bladder disease. H. C. MOFFITT. *Cal. St. J. M.*, 1913, xi, 306.

Surgical treatment of gall-bladder disease. W. I. TERRY. *Cal. St. J. M.*, 1913, xi, 304.

Anomalous ligament of the gall-bladder. KONJETZNY. *Zentralbl. f. Chir.*, 1913, xl, 1408.

Cholecystostomy by oblique fistula. JOSEPH WIENER. *Surg., Gynec. & Obst.*, 1913, xvii, 232.

What is the origin of pure cholesterol calculi? ASCHOFF. *München. med. Wchnschr.*, 1913, lx, No. 32.

The origin of so-called "white bile" in absolute and permanent occlusion of the choledochus. BERTOG. *Mitt. a. d. Grenzgeb. d. Med. u. Chir.*, 1913, xxvi, No. 1.

So-called biliary peritonitis. SICK and FRANKEL. *Beitr. z. klin. Chir.*, 1913, lxxxv, No. 3.

Hæmorrhagic pancreatitis. W. D. HAINES. *Lancet-Clin.*, 1913, cx, 198.

Chronic pancreatitis. SCHMIDT. *Mitt. a. d. Grenzgeb. d. Med. u. Chir.*, 1913, xxvi, No. 1.

Acute necrosis of the pancreas. J. GOBIET. *Wien. klin. Wchnschr.*, 1913, xxvi, 1381.

A case of fatty necrosis of the pancreas. CHODJACHE. *Russk. Vrach.*, St. Petersburg, 1913, xii, No. 31.

A rare case of hydatid cyst of the pancreas cured by marsupialization. G. PARLAVECCHIO. *Pensiero méd.*, 1913, No. 2. [631]

Surgery of the pancreas. HABS. *Med. Klin.*, Berl., 1913, ix, 1277.

The amount of work done by the spleen. FRITZ. *Verzár. Biochem. Ztschr.*, 1913, liii, 69.

Pathology of the function of the spleen. EPPINGER. *Berl. klin. Wchnschr.*, 1913, l, No. 34.

A new contribution on physiology of the spleen; iron content of the bile and blood of splenectomized animals. ANGELO PUGLIESESE. *Biochem. Ztschr.*, 1913, lii, 423.

Subcutaneous traumatic rupture of the spleen and its treatment. L. NORRLIN. *Upsala Läkaref. Förh.*, N. F. 1913, xviii, 214. [631]

A rare disease of the spleen; sarcoma alveolaris or endothelioma lienis. COULKOFF. *Vrach. Gaz.*, 1913, vi, Nos. 16-17-18.

Banti's disease. R. GRÜTZNER. *Fortschr. d. Med.*, 1913, xxxi, 869.

The relation of the spleen to active immunity from tumors. A supplement and correction with regard to the article of the same title by H. Apolani. A. BRAUNSTEIN. *Ztschr. f. Immunitätsforsch.*, 1913, xviii, 330.

The inhibitory influence of the spleen upon the growth of rat sarcomas. PAUL BIACH and OSCAR WELTMANN. *Wien. klin. Wchnschr.*, 1913, xxvi, 1115. [632]

A case of splenomegaly. KRAUS. *Berl. Wchnschr.*, 1913, l, No. 31.

The treatment of primary splenomegaly, especially by exsplenopexy. PARLAVECCHIO. *Clin. chir.*, Milano, 1913, xxi, No. 7.

Splenomegaly associated with hepatic cirrhosis during the ascitic period, splenectomy and Calma's operation; contribution to the study and treatment of chronic splenomegaly due to thrombosis of the splenic circulatory system. TANSINI and MORONE. *Rev. de chir.*, Par., 1913, xxxiii, No. 8.

Miscellaneous

Diagnosis in abdominal emergencies. WILLIAM SHEEN. *Clinical J.*, 1913, xlii, 273.

Clinical interpretation of chronic abdominal enlargement in children, with especial reference to a new differential sign between rachitis and tuberculous peritonitis. H. B. SHEFFIELD. *Med. Rec.*, 1913, lxxxiv, 382.

Sensitiveness of the abdominal cavity. KAPPIS. *Mitt. a. d. Grenzgeb. d. Med. u. Chir.*, 1913, xxvi, No. 3.

The hæmostatic action of fatty tissue in injuries of parenchymatous organs of the abdomen. A. POLENOFF and M. LADYGIN. *Vrach. Gaz.*, St. Petersburg, 1913, xx, 737. [632]

The elevated head and trunk position in the treatment of surgical lesions of the abdomen. R. S. FOWLER. *Tr. Internat. Cong. Med.*, Lond., 1913, Aug. [632]

Concerning visceral organisms. A. CARREL. *J. Exp. Med.*, 1913, xviii, 155. [633]

SURGERY OF THE EXTREMITIES

Diseases of Bones, Joints, Muscles, Tendons— General Conditions Commonly Found in the Extremities

Köhler's bone disease. C. BLES. *München. med. Wchnschr.*, 1913, lx, 1941.

Tuberculosis of bones and joints. VEREBELY. *Pest. med.-chir. Presse*, Budapest, 1913, xlix, No. 33.

The employment of the X-ray in tuberculosis of bones and joints. E. A. OPPENHEIM. *Berl. klin. Wchnschr.*, 1913, l, 1433.

The treatment of surgical tuberculosis by natural and

artificial light. OSKAR VULPIUS. *Strahlentherapie*, 1913, iii, 104.

The treatment of surgical tuberculosis by artificial light. RICHARD HAGEMANN. *Deutsche med. Wchnschr.*, 1913, xxxix, 1450.

Heliotherapeutic and air treatment of surgical tuberculosis. PAUL GLÄSSNER. *Berl. klin. Wchnschr.*, 1913, l, 1434.

The conservative methods of treating surgical tuberculosis. ED. MENNE. *Deutsche Ztschr. f. Chir.*, 1913, cxxiii, 357.

Tuberculin therapy in surgical tuberculosis with the correct dosage accurately determined by the cutaneous reaction. B. Z. CASHMAN. *Am. J. M. Sc.*, 1913, cxlvi, 213.

Syphilitic bone and joint conditions. H. W. FRAUENTHAL. *Tr. Internat. Cong. Med.*, Lond., 1913, Aug. [633]

Acute osteomyelitis and plastic operations on bone in childhood; from the material of the Emperor and Empress Frederick Children's Hospital from 1890-1912. F. WACHSNER. *Arch. f. Kinderh.*, Stuttg., 1913, lx-lxi, *Festschr. f. Adolf Baginsky*, 748. [634]

Acute osteomyelitis of the pubes. THOMSCHKE. *Deutsche Ztschr. f. Chir.*, 1913, cxxiii, 290.

Traumatic dissecting epiphysitis of the tibia in adolescence. EBBINGHAUS. *Deutsche med. Wchnschr.*, 1913, xxxix, No. 32.

Typhoid periostitis. H. W. DACHTLER. *Tr. Am. Röntg. Ray. Soc.*, Boston, 1913, Oct. [634]

Family chondro dystrophy. G. A. WAGNER. *Arch. f. Gynäk.*, 1913, c, 70.

Experimental scorbutus and the röntgen-ray diagnosis of scorbutus. TALBOT, DODD, and PETERSON. *Boston M. & S. J.*, 1913, clxix, 232. [634]

The pathology of idiopathic osteopsathyrosis. DENIS G. ZESAS. *Deutsche Ztschr. f. Chir.*, cxxiii, 380.

Blue sclera and osteopsathyrosis. A. PETERS. *Klin. Monatsbl. f. Augenh.*, 1913, li, 594.

Echinococci of the bones. A. EBERLE. *Chirurgia*, St. Petersburg, 1913, xxxiii, 781.

Osteomalacia and psychosis. W. M. VAN DER SCHEER. *Arch. f. Psychiat.*, 1913, l, 845. [635]

Multiple cartilaginous exostoses. G. AVÉ-LALLEMANT. *Fortschr. a. d. Geb. d. Röntgenstr.*, 1913, xx, 439.

Bone cysts; osteitis fibrosa and multiple exostoses. N. PAUS. *Norsk. Mag. f. Lægevidensk.*, Christiania, 1913, lxxiv, 634. [635]

Two cases of primary endothelioma of the bones. ABETTI. *Policlin.*, Roma, 1913, sez. chir., xx, No. 8.

Regeneration of bone from periosteum. S. L. HAAS. *Surg., Gynec. & Obst.*, 1913, xvii, 164. [635]

Unusual bone lesions. ADOLPH HARTUNG. *Tr. Am. Röntg. Ray Soc.*, Boston, 1913, Oct. [636]

Diseases of joints and bone marrow. LEONARD W. ELY. *Am. J. Surg.*, 1913, xxvii, 309. [636]

Tabetic osteoarthropathies. M. J. CETCHOWITCH. *Russk. Vrach.*, 1913, xii, 960.

Physiotherapy of joint diseases, especially tuberculosis. M. WILMS. *Ztschr. f. orthop. Chir.*, 1913, xxxii, 321.

The technique of diathermal treatment of affections of the joints. ALBERT E. STEIN. *Deutsche med. Wchnschr.*, 1913, xxxix, 1308.

Modern out-patient and ambulatory treatment of joint tuberculosis, especially tuberculosis of the hip. BECKER and PAPPEDECK. *Med. Klin.*, Berl., 1913, No. 34.

A case of congenital ankylosis of the humero-ulnar joint. CRAMER. *Zentralbl. f. chir. u. mech. Orthop.*, 1913, vii, No. 9.

Presentation of operated cases of ankylosis. A. SCHANZ. *Zentralbl. f. Chir.*, 1913, xl, 1339.

Uric acid arthritis in the X-ray picture. EUGEN JACOBSON. *Mitt. a. d. Grenzgeb. d. Med. u. Chir.*, 1913, xxvi, 531.

The etiology of arthritis deformans. KARL WAGNER. *Wien. med. Wchnschr.*, 1913, lxiii, 1907.

Treatment of arthritis deformans. G. A. WOLLENBERG. *Ztschr. f. orthop. Chir.*, 1913, xxxii, 442.

Gonorrhœal arthritis. MAUCLAIRE. *Prog. méd.*, Par., 1913, xlv, No. 31.

Good effect of local use of salicylic acid in gonorrhœal arthritis. A. S. SOLOWZOWA. *Russk. Vrach.*, 1913, xii, 992.

Etiology of rheumatism. WOODSON MOSS. *Med. Herald*, 1913, xxxii, 283.

Acute rheumatism. FREDERICK H. THOMPSON. *Med. Sentinel*, 1913, xxi, 1074.

Treatment of rheumatism. E. H. MARTIN. *Med. Herald*, 1913, xxxii, 285.

Chondroma of the capsule of the shoulder joint. HAGEMANN. *Med. Klin.*, Berl., 1913, ix, No. 31.

Hip-joints. CRAMER. *Zentralbl. f. chir. u. mech. Orthop.*, 1913, vii, No. 9.

The mechanical treatment of hip disease. J. RIDLON. *Tr. Internat. Cong. Med.*, Lond., 1913, Aug. [636]

Contracture of the hip joint in tuberculous coxitis. R. WERNDORFF. *Ztschr. f. orthop. Chir.*, 1913, xxxii, 201.

The pathology of the knee-joint. FERDINAND BÄHR. *Deutsche med. Wchnschr.*, 1913, xxxix, 1462.

Penetrating wounds of the knee-joint. MÜLLER. *Zentralbl. f. Chir.*, 1913, xl, 1108.

Injection of vaseline into the joints. THORKILD RÖVSING. *Hosp.-Tid.*, Kjøbenh., 1913, lvi, 859.

Atrophy of muscles in affections of the joints. J. H. TEUJI. *Nippon-geka-Gakkai-Zasshi*, 1913, xiv, 172.

Primary muscle sarcomata. F. LANDOIS. *Versamml. d. Gesellsch. deutscher Naturforsch. u. Ärzte*, 1913, ii, ix.

The cavernous form of muscular angioma. BORCHARD. *Beitr. z. path. Anat. u. z. allg. Path.*, 1913, lvii, 30.

Operative paralysis of the muscular triangularis. MANASSE. *Zentralbl. f. Chir.*, 1913, xl, No. 33.

Retrocalcaneal bursitis. CHARLES STANLEY WHITE. *N. Y. M. J.*, 1913, xcvi, 263.

A case of gonorrhœal tendovaginitis. RAUSCHENBERGER. *München. med. Wchnschr.*, 1913, lx, 1828.

Simple ganglion at the wrist. EDWARD H. SCHOTT. *Hosp. Bull. Univ. Md.*, 1913, ix, 107.

Pathological changes in the tendon sheaths after injuries to the fingers. W. STEMPER. *Ärztl. Sachverst.-Zeit.*, 1913, xix, 340.

Operative treatment of gangrene of the lower extremities. A. LIDSKJ. *Vrach. Gaz.*, St. Petersburg, 1913, xx, 991.

Fractures and Dislocations

Address in Surgery — Fractures and their treatment. J. ALEX. HUTCHISON. *Canad. J. Med. & Surg.*, 1913, xxxiv, 93.

Spontaneous fractures as a result of syphilis. RUHEMANN. *Ärztl. Sachverst.-Zeit.*, 1913, xix, 357.

Spontaneous fracture in carcinoma of the bones. G. W. HAWLEY. *Am. J. Orth. Surg.*, 1913, xi, 139.

The reposition of fractured bones under local anæsthesia. B. DOLLINGER. *Zentralbl. f. Chir.*, 1913, xl, 763. [637]

Juxta-epiphyseal sprain and sprain fracture of the lower end of the radius. KELLOGG SPEED. *Surg., Gynec. & Obst.*, 1913, xvii, 241. [637]

The nail extension treatment of fractures. PETSCHKE. *Zentralbl. f. Chir.*, 1913, xl, No. 31.

Comment upon Kulenkampff's article entitled "On the technique of Steinmann's nail extension treatment." STEINMANN. *Zentralbl. f. Chir.*, 1913, xl, No. 31.

Reply to Steinmann's remarks. KULENKAMFF. *Zentralbl. f. Chir.*, 1913, xl, No. 31.

Experiences with Steinmann's nail extension method in fractures of the femur. JOHN C. A. GERSTER. *Am. J. M. Sc.*, 1913, cxlvi, 157.

An apparatus for nail extension treatment which will not become displaced. N. SPIEGEL. *Deutsche med. Wchnschr.*, 1913, xxxix, 1205.

Treatment of radial fractures. A. TROELL. *Allm. sven. Läkartidn.*, Stockholm, 1913, x, 577. [638]

Fracture of the humerus with radial paralysis. DELBET. *J. d. Prat.*, Par., 1913, xxvii, No. 31.

Current methods of treating fractures of the limbs. VEGNER. *Chirurgia*, St. Petersburg, 1913, xxxiii, No. 193.

Fractures and pseudarthroses of the bones of the leg in infants. KIRMISSON. *J. d. Prat.*, Par., 1913, xxvii, No. 32.

Fracture of the femur. G. E. ARMSTRONG. *Tr. Internat. Cong. Med.*, Lond., 1913, Aug. [638]

Rare form of fracture of the knee-joint. O. BREHM. *St. Petersburg. med. Ztschr.*, 1913, xxxviii, 189.

Fractures of the knee-joint. GOTTSTEIN. *Zentralbl. f. Chir.*, 1913, xl, 1145.

An interesting case of fracture of the lower third of the leg, with epiphyseal separation of the tibia; its mechanism and the mechanism in general of fractures of the lower third of the leg. BOUVIER. *J. d. med. de Bordeaux*, 1913, lxxxiv, No. 32.

Three cases of complicated luxation. ALHAIQUE. *Rif. med.*, Naples, 1913, xxix, No. 31.

A rare complication of luxation of the humerus. CIPOLLINO. *Gazz. d. osp. e d. Clin.*, Milano, 1913, xxxiv, No. 93.

A typical injury of the medial condyle of the femur. PAUL EWALD. *München. med. Wchnschr.*, 1913, lx, 1662.

Congenital backward luxation of the knee-joint. LAZARAGA. *Med. Klin.*, Berl., 1913, ix, 1037.

A rare case of congenital luxation of the knee-joint. ALFRED WACHTER. *Deutsche Ztschr. f. Chir.*, 1913, cxxiii, 190.

Injury of the crucial ligaments of the knee-joint. H. GÖTJES. *Deutsche Ztschr. f. Chir.*, 1913, cxxiii, 221.

Luxation of the internal meniscus of the right knee; reduction. ROUX DE BRIGNOLLES. *Marseille méd.*, 1913, l, No. 16.

Lateral displacement of the meniscus. BLECHER. *Deutsche Ztschr. f. Chir.*, 1913, cxxiii, 601.

Rare traumatic injuries of the foot (posterior luxation of the foot). P. M. FRASSIN. *Chirurgia*, St. Petersburg, 1913, xxxiii, 808.

Luxation of the foot below the ankle. NIC PAUS. *Norsk. Mag. f. Lægevidensk.*, Christiania, 1913, lxxiv, 634.

Surgery of the Bones, Joints, etc.

The open treatment of fractures; a few remarks. P. DE WITT. *Nashville J. M. & S.*, 1913, cvii, 337.

An absorbable plate for use in open treatment of fractures. ALEXIUS MCGLANNAN. *J. Am. M. Ass.*, 1913, lxi, 333.

Open treatment of fractures (osteosynthesis) with special consideration of the permanent results obtained. TRÖLL. *Nord. med. Arch.*, Stockholm, 1913, xli, (Chir. F. 1).

A review of the treatment of old fractures of the patella. GUÉNU and GATELLIER. *Rev. de chir.*, Par., 1913, xxxiii, No. 8.

Cauterization of bone for loss of substance before filling the cavity. FIORAVANTI. *Ref. med.*, Naples, 1913, xxix, No. 31.

Plugging bone cavities with free transplantation of fat. M. KRABBEL. *Beitr. z. klin. Chir.*, 1913, lxxxv, 400. [639]

A case of bone graft from one man to another for the restoration of the lower half of the femur. RÖVSING. *Hosp.-Tid.*, Kjøbenhavn., 1913, lvi, No. 31.

Three attempts at grafts of bones and joints. MAUCLAIRE. *Bull. med.*, Par., 1913, xxvii, No. 66.

Repair of a phalanx of a finger. LEXER. *München. med. Wchnschr.*, 1913, lx, 1855.

Treatment of syndactylism. G. LERDA. *Zentralbl. f. Chir.*, 1913, xl, 1396.

A simplified sole for wear in flat-foot. BRANDENBERG. *Zentralbl. f. chir. u. mech. Orthop.*, 1913, vii, No. 9.

Bandage to be applied under plaster in treatment of club-foot. SPRENGEL. *München. med. Wchnschr.*, 1913, lx, 1490.

Human carriers in poliomyelitis. W. P. LUCAS and R. E. OSGOOD. *Am. J. Orth. Surg.*, 1913, xi, 135. [640]

SURGERY OF THE SPINAL COLUMN AND CORD

- Röntgen ray diagnosis of the lumbar spine and the sacro-iliac articulations. C. H. BUCHOLZ. *Tr. Am. Röntg. Ray Soc.*, Boston, 1913, Oct. [640]
- Compressed fracture of the spinal column while skiing. GRÖNDAHL. *Norsk. Mag. f. Lægevidn.*, Christiana, 1913, lxxiv, No. 8.
- Congenital presacral tumors. FARIN. *Deutsche Ztschr. f. Chir.*, 1913, cxxiii, Nos. 5-6.
- A frequent anomaly of the lower thoracic spinal column. WILHELM GUNDERMANN. *München. med. Wchnschr.*, 1913, lx, 1878.
- Defects within the lower spinal canal. HORACE REED. *J. Okla. St. Med. Ass.*, 1913, vi, 114.
- The clinical significance of occult spina bifida. EUGEN BIBERGEIL. *Berl. klin. Wchnschr.*, 1913, l, 1481.
- Ankylosis of the spinal column. R. GOLANT. *Russk. Vrach, St. Petersburg.*, 1913, xii, 1029.
- Rigidity of ankylosis of the spine with nervous symptom complex. BECHTEREFF. *Russk. Vrach, St. Petersburg.*, 1913, xii, Nos. 30-31.
- Rigidity of the vertebral column. HOLANT. *Russk. Vrach, St. Petersburg.*, 1913, xii, No. 29.
- Scoliosis; its prognosis. JOHN L. PORTER. *Am. J. Orth. Surg.*, 1913, xi, 42.
- Hysterical scolioses. REINGER. *Berl. klin. Wchnschr.*, 1913, l, 1495.
- Apprentice's scoliosis. J. ELSNER. *Ztschr. f. orth. Chir.*, 1913, xxxii, 277.
- Congenital scoliosis traceable to the presence of a semi-vertebra. DUBREUIL-CHAMBARDEL. *Arch. gén. de chir.*, Par., 1913, vii, No. 7.
- The physiological treatment of pathological scoliosis by rotation. A. M. FORBES. *Brit. M. J.*, 1913, ii, 536.
- Modern treatment of scoliosis; how to treat its different forms. CALOT. *J. d. Prat., Par.*, 1913, xxvii, No. 34.
- The treatment of scoliosis. R. W. LOVETT. *Tr. Internat. Cong. Med.*, Lond., 1913, Aug. [641]
- The treatment of lateral curvature of the spine by the Forbes method. Z. B. ADAMS. *Am. J. Orth. Surg.*, 1913, xi, 97. [641]
- The rotation treatment of scoliosis. A. M. FORBES. *Am. J. Orth. Surg.*, 1913, xi, 75.
- The treatment of scoliosis, especially by Abbott's method. F. BITTNER. *Prag. med. Wchnschr.*, 1913, xxxviii, 471.
- Abbott's technique in the treatment of scoliosis. KOSINSKI. *Przegl. lek.*, Kraków, 1913, lii, No. 13.
- The treatment of scoliosis after Abbott's method. P. VERSTRAETEN. *Belgique med.*, 1913, xx, 375.
- Treatment of scoliosis by Abbott's method. VAN NECK. *J. med. de Brux.*, 1913, xxiii, No. 30.
- Abbott's method of treating grave cases of scoliosis. DELCHEF. *Ann. de la Policlin. centr. de Brux.*, 1913, xiii, 161.
- Corrective jackets in the treatment of structural scoliosis with special reference to mensuration and record. A. H. FREIBERG. *Am. J. Orth. Surg.*, 1913, xi, 29.
- An introduction to the symposium on lateral curvature. A. G. COOK. *Am. J. Orth. Surg.*, 1913, xi, 1.
- Movements or positions of the normal spine and their relations to lateral curvature. E. G. ABBOTT. *Am. J. Orth. Surg.*, 1913, xi, 13.
- A consideration of the correction of the fixed types of lateral curvature, complicated by visceral derangements, especially those of the cardiac variety, with a slight modification of Abbott's method. R. O. REISENBACH. *Am. J. Orth. Surg.*, 1913, xi, 46.
- The forcible correction (Abbott's method) of roto-lateral curvature of the spine: a preliminary report. WALTER F. STERN. *Ohio St. M. J.*, 1913, ix, 275.
- A case of cervical spondylitis cured by heliotherapy. KIENAST and FRANKFURTER. *Wien. med. Wchnschr.*, 1913, lxii, No. 35.
- The treatment of spondylitis. A. HENLE. *Verhandl. d. Gesellsch. deutscher Naturforsch. u. Ärzte*, 1912, Part 2, 192.
- What to do after corrective jackets are removed. E. H. BRADFORD. *Am. J. Orth. Surg.*, 1913, xi, 63.
- A case of acute gonorrhoeal spondylarthritis. HEINRICH SANDER. *München. med. Wchnschr.*, 1913, lx, 1830.
- Transplantation of a part of the tibia in the treatment of Pott's disease. GUILLLOT. *Arch. med.-chir. de Normandie*, 1913, iv, No. 7.
- Anomalies of the sacro-lumbar articulation. E. S. HATCH. *N. Orl. M. & S. J.*, 1913, lxvi, 119.
- The treatment of chronic progressive diseases of the spinal cord by X-rays with an account of two cases. FRANCIS HERNAMAN-JOHNSON. *Brit. M. J.*, 1913, ii, 299.
- The treatment of spondylitic paralysis. P. BADE. *München. med. Wchnschr.*, 1913, lx, 1432. [641]
- Late epidermitization of myelomeningoceles. M. R. BONSMANN. *Virchow's Arch. f. path. Anat.*, etc., 1913, cxxiii, 131.

SURGERY OF THE NERVOUS SYSTEM

- New facts in regard to the nature of sciatica and new methods for the operative treatment of the disease. A. STOFFEL. *München. med. Wchnschr.*, 1913, lx, 1365. [642]
- Some cases of sciatica cured by the injection of strychnine. RETIVOFF. *Vrach. Gaz.*, St. Petersburg., 1913, xx, No. 32.
- Treatment of sciatica. SCHURIG. *München. med. Wchnschr.*, 1913, lx, No. 32.
- Gliomatous neuro-epitheliomata in the gluteal region. C. KOBER. *Ztschr. f. d. ges. Neurol. u. Psychiatr.*, 1913, xvii, 500.
- Traumatic bilateral external rectus paralysis with transient paresis of the left facial nerve. E. A. SHUMWAY. *Med. Rec.*, 1913, lxxxiv, 340.
- The operative treatment of traumatic paralysis of peripheral nerves. LUXENBOURG. *Deutsche Ztschr. f. Chir.*, 1913, cxxiii, Nos. 5-6.
- Treatment of neuralgia of the brachial plexus with Kulenkampff's anaesthesia. M. TÖBBEN. *München. med. Wchnschr.*, 1913, lx, 1883.
- Stöffel's operation. KÖLLIKER. *Zentralbl. f. Chir.*, 1913, xl, 1372.

DISEASES AND SURGERY OF THE SKIN, FASCIA, APPENDAGES

Treatment of burns from heliotherapy. AIMS. Gaz. d. Hôp., Par., 1913, lxxxvi, No. 88.

Treatment of burns from heliotherapy. MIRAMOND DE LA ROQUETTE. Gaz. d. Hôp., Par., 1913, lxxxvi, No. 96.

Treatment of burns by amidoazotoluol. BERLATZKY. Pract. Vrach, St. Petersburg., 1913, xii, No. 31.

Treatment of burns by Røvsing's method. IPSSEN. Hosp.-Tid., Kjøbenh., 1913, lvi, No. 31.

Burns treated after the method of Røvsing. O. WULFF. Hosp.-Tid., Kjøbenh., 1913, lv, 912.

A case of primary actinomycosis of the skin; incubation and latent period of actinomycosis. HOLLAND. Norsk. Mag. f. Lægevidn., Christiania, 1913, lxxiv, No. 8.

Neuroma cutis (dolorosum). M. L. HEIDINGSFELD. J. Am. M. Ass., 1913, lxi, 405.

Case of X-ray ulcer lasting eleven months with no tendency to healing; recovery after use of Zeller's paste. R. EBEN. Prag. med. Wchnschr., 1913, xxxviii, 498.

Treatment of varicose ulcers with simple adhesive

plaster bandages. WERTHEIMER. München. med. Wchnschr., 1913, lx, 1490.

Treatment of chronic ulcers of the leg, with special reference to symptomatology and diagnosis. E. ADAMS. Internat. J. Surg., 1913, xxvi, 288.

Free transplantation of fascia. J. SSOBOKEFF. Russk. Vrach, St. Petersburg., 1913, xii, 1096.

Free transplantation of fascia. HANS HERMANN SCHMID. Gynäk. Rundschau, 1913, vii, 429.

Experimental work in fascia transplantation. VALENTIN. Deutsche med. Wchnschr., 1913, xxxix, No. 31.

Experimental researches on homoioplastic transplantation of fascia. VALENTIN. Beitr. z. klin. Chir., 1913, lxxxv, No. 3.

Presents tatus of autoplasic free transplantation of fascia. KIRSCHNER. Beitr. z. klin. Chir., 1913, lxxxvi, No. 1.

Some modifications in the technique of Ollier-Thiersch grafts. HARDOUIN. Presse méd., Par., 1913, xxi, No. 68.

Skin grafting. WALTER R. PARKER. J. Mich. St. Med. Soc., 1913, xii, 414.

MISCELLANEOUS

Clinical Entities—Tumors, Ulcers, Abscesses, etc.

Diagnosis and pathology of the polyglandular system. KARL CSÉPAI. Deutsche Arch. f. klin. Med., 1913, cxi, 271.

Predisposition for tumors. M. GOLDZIEHER and E. ROSENTHAL. Ztschr. f. Krebsforsch., 1913, xiii, 321.

Generalized sarcomatosis. KLINGEBIEL. J. de Med. de Bordeaux, 1913, lxxxiv, No. 32.

The question of sarcomatous tumors in dogs. ANTISCHKOFF. Charkow. med. J., 1913, xv, 271.

Treatment of lymphosarcoma. FABIAN. München. med. Wchnschr., 1913, lx, No. 34.

The present status of our knowledge of malignant granuloma, with special consideration of its etiology. OSCAR MEYER. Folia hæmatol., 1913, xv, 205.

Erethistic granuloma. B. MAYHOFER. Osterr.-ungar. Vierteljahrschr. f. Zahnk., 1913, xxix, 169.

Chorio-epithelioma. C. B. KINYON. Internat. J. Surg., 1913, xxvi, 285.

Fibroma with twisted pedicle. S. POZZI and G. ROUHIER. Bull. et mém. Soc. anat. de Par., 1913, lxxxviii, 365.

Note on a case of symmetrical lipomatosis. MARTIN. Paris méd., Par., 1913, No. 36.

A case of botryomycosis in man. BOSELLINI. Clin. chir., Milano, 1913, xxi, No. 7.

Tropical abscess. ZUR WERTH. Deutsche mil.-Ärztl. Ztschr., 1913, xlii, 584.

Abscess due to streptothrix eppingeri (actinomyces asteroides) resembling a staphylococcal infection. W. BROUGHTON-ALCOCK. Brit. M. J., 1913, ii, 299.

Some unusual cases of hydatid disease. H. O'HARA. Med. Press & Circ., 1913, xcvi, 224.

The surgical cure of leprosy, based on a new theory of infection. E. S. GOODHUE. N. Y. M. J., 1913, xcvi, 266.

Case of artificial phlegmon. MILENOUCHKINE. Voenno-med. J., 1913, ccxxxvii, No. 4.

Report of a case of rabies. J. CHRIS O'DAY. Med. Sentinel, 1913, xxi, 1070.

Report of a case of rabies. CALVIN S. WHITE. Med. Sentinel, 1913, xxi, 1072.

Report of a case of rabies. LOUIS BUCK. Med. Sentinel, 1913, xxi, 1073.

Anthrax and its treatment. W. A. LIGNON. Ky. M. J., 1913, xi, 648.

The importance of pain and shock in operative mortality. LEIGH F. WATSON. J. Okla. St. Med. Ass., 1913, vi, 121.

The kinetic theory of shock and its prevention through anoci-association (shockless operation). G. W. CRILE. Cleveland M. J., 1913, xii, 513.

Morphological changes in tissue with changes in environment; replacement of surface epithelium of grafted tissue by adjacent epithelium. G. M. SMITH. J. Med. Research, 1913, xxviii, 423. [644]

Life of tissue outside of organism. PETROFF. Vrach. Gaz., St. Petersburg, 1913, xx, No. 30.

Cultivation of tissues outside the organism. GUIRGOLAFF. Vrach. Gaz., St. Petersburg, 1913, xx, Nos. 30-31.

Experiments with the cultivation of tissues. DRONOVSKY and POLEFF. Vrach. Gaz., St. Petersburg, 1913, xx, No. 29.

Spontaneous autoplasty by gradual extension of tissue, due to a position allowing immediate union. MORESTIN. Presse méd., Paris, 1913, xxi, No. 65.

Importance of free transplantation in modern surgery. H. KÜTTNER. Naturwissensch., 1913, i, 513. [645]

The clinical character and the treatment of railway injuries. W. W. SSISEMSKI. Russk. Vrach, St. Petersburg, 1913, xii, 24. [645]

Injuries by frost in weather above freezing temperature. A. KÖHLER. Zentralbl. f. Chir., 1913, xl, 1362.

Sera, Vaccines and Ferments

Study of the sources of error in the use of dialysis as a method of serologic research; effect of the blood content of the organ. ABDERHALDEN and WEIL. München. med. Wchnschr., 1913, lx, No. 30.

Serologic diagnosis of malignant disease and pregnancy by Abderhalden's method. GAMBAROFF. Novoev Med., St. Petersburg, 1913, vii, No. 14.

Diagnosis of cancer by Abderhalden's method. VOLTER. Russk. Vrach, St. Petersburg, 1913, xii, No. 32.

Value of the antitryptic reaction of the blood serum in the diagnosis of cancer. Vrach. Gaz., 1913, vi, Nos. 24-25.

The present status of serum therapy. W. B. JENNINGS. N. Y. M. J., 1913, xcvi, 420.

A case of serum therapeutics. M. RAM. Indian. M. Gaz., 1913, xlviii, 308.

Marmorek's anti-tuberculosis serum. REIMANN. Beitr. z. klin. Chir., 1913, lxxxv, No. 3.

Treatment of surgical tuberculosis with Marmorek's serum. PAVESIO. Rif. med., Naples, 1913, xxix, Nos. 33-34.

Tuberculin treatment. H. MACKENZIE. Lancet, Lond., 1913, clxxxv, 521.

Theses on tuberculin treatment. SAHLI. Lancet, Lond., 1913, clxxxv, 379. [646]

The anti-streptococci serum and electragol in the treatment of otogenous septic generalized infection. JOHANN LANG. Arch. f. Ohrenh., 1913, xc, 252.

Serum diagnosis of echinococcus. ZILBERG and CHMELITZKY. Charov. med. J., 1913, xvi, No. 1.

Anti-streptococcus serum. G. H. WEAVER. J. Am. M. Ass., 1913, lxi, 661.

A new diphtheria antitoxin. E. VON BEHRING. Deutsche med. Wchnschr., 1913, xxxix, 873. [646]

Alterations produced in complement-containing serums by introduction of lecithin. J. CRUICKSHANK and T. J. MACKIE. J. Pathol. & Bacteriol., 1913, xviii, No. 1. [646]

Clinical observations upon the influence of gonococcus vaccines in chronic gonorrhoeal arthritis. SSEMENOFF. Russk. Vrach, St. Petersburg, 1913, xii, 246.

Sterilized pus for the treatment of infections. V. B. NESFIELD. Indian. M. Gaz., 1913, xlviii, 307.

The local specific therapy of infections. SIMON FLEXNER. J. Am. M. Ass., 1913, lxi, 447.

A further contribution on the specificity of the protective ferments; the action of the blood serum of pregnant rabbits upon various organs. ABDERHALDEN and SCHIFF. München. med. Wchnschr., 1913, lx, 1923.

The reaction of the antigen antibodies and their employment in cancer. O. SCHMIDT. München. med. Wchnschr., 1913, lx, 1858.

Immunity by scientific bacterization versus natural immunization in self-limiting diseases of bacterial origin. ROEHR. N. Y. M. J., 1913, xcvi, 229.

A contribution to the relation between proteid cleavage products and anaphylaxis. AUER and VAN SLYKE. J. Exp. Med., 1913, xviii, 210. [647]

Blood

Studies in circulation. HUGO RIBBERT. Virchow's Arch. f. path. Anat., etc., 1913, cxliii, 17.

Studies in the circulation in man. VI. Observations on the blood flow in the hands (mainly) in anaemia. G. N. STEWART. J. Exp. Med., 1913, xviii, 113.

The value of the auscultatory method for the determination of blood pressure. W. E. RICHARD SCHOTTSTAEDT. Ohio St. M. J., 1913, ix, 373.

Blood pressure in infants, especially in gastro-enteritis. H. K. HILL. Arch. Pediatrics, 1913, xxx, 588.

Variations of the urea content of the blood, with a practical method for its determination. G. W. McCASKEY. Med. Rec., 1913, lxxxiv, 380.

Hard traumatic oedema. R. MORIAN. Verhandl. d. Gesellsch. deutscher Naturforsch. u. Ärzte, 1913, ii, part 2, 137.

The operative treatment of chronic oedema. W. BÜCKER. München. med. Wchnschr., 1913, lx, 1774.

Acute myelogenous leucemia or a peculiar sepsis due to streptococci. OSCAR GANS. Beitr. z. path. Anat. u. z. allg. Path., 1913, lvi, 441.

The surgical treatment of certain forms of icterus. A. W. MAYO-ROBSON. Wien. med. Wchnschr., 1913, lxiii, 2020.

Hæmorrhage in scarlet fever. KLIMENKO. Russk. Vrach, St. Petersburg, 1913, xii, 615.

Neurotic hæmorrhage. C. HART. Frankfurt. Ztschr. f. Pathol., 1913, xiii, 242.

Contributions to hæmophilia. H. HEYTER. Mitt. a. d. Hamburg, Staatskrankenanst., 1913, xiv, 9. [647]

Thrombosis of the splenic and portal veins. GOLDMAN. Deutsche med. Wchnschr., 1913, xxxix, No. 32.

Chronic mesenteric thrombosis. JOHN C. STANLEY. St. Paul M. J., 1913, xv, 381.

The treatment of thrombosis of the bulb of the jugular vein. BLUMENTHAL. Ztschr. f. Ohrenh. u. f. d. Krankh. d. Luftw., 1913, lxix, No. 1.

Thrombosis of the condyloid vessels. BEYER. Beitr. z. Anat., Physiol., Path. u. Therap. d. Ohres, d. Nase u. d. Halses, 1913, xi, Nos. 4-6.

Venous thrombosis of the right arm, called phlebitis from exertion. PELLOT. *Paris méd.*, 1913, No. 37.

Fat embolism. WILLIAM S. WALSH. *Hosp. Bull. Univ. Md.*, 1913, ix, 107.

Fat embolism of the large circulatory vessels and its causes. FROMBERG. *Mitt. a. d. Grenzgeb. d. Med. u. Chir.*, 1913, xxvi, No. 1.

Experimental researches on gas embolism following injection of air into the bladder. CARLO CANTINI. *Bull. d. sc. med.*, Bologna, 1913, lxxxiv, 491.

Direct transfusion of blood. H. FLÖRCKEN. *Verhandl. d. Gesellschaft. deutscher Naturforsch. u. Ärzte*, 1913, ii, part 2, 178.

A simplified method of direct blood transfusion with self-retaining tubes. L. H. LANDON. *J. Am. M. Ass.*, 1913, lxi, 490.

Blood and Lymph Vessels

Study of aneurisms of the small vessels; a case of traumatic aneurism of the radial artery from a subcutaneous lesion. DOBROVOLSKAIA. *Pract. Vrach, St. Petersburg*, 1913, xii, No. 29.

Aneurism of arteries of small caliber. DOBROVOLSKAIA. *Beitr. z. klin. Chir.*, 1913, lxxxv, No. 3.

A case of aneurism of the abdominal aorta associated with perforation of the stomach by a round ulcer. S. M. ZYPKIN. *Deutsche med. Wchnschr.*, 1913, xxxix, 1145.

Varicose veins and accidents. LINIGER. *Monatschr. f. Unfallh. u. Invalidenwes.*, 1913, xx, 209.

A palpatory symptom of valvular insufficiency in beginning and invisible varices. E. HESSE. *Beitr. z. klin. Chir.*, 1913, lxxxv, 591. [647]

Operative treatment of varices. R. C. ÖHMANN. *Finska läk.-sällsk. handl.*, 1913, lv, 1.

Operative treatment of varicose veins after a very small incision. HOLFELDER. *Zentralbl. f. Chir.*, 1913, xl, No. 33.

Sapheno-femoral anastomosis in varicose veins. WEICHERT. *Berl. klin. Wchnschr.*, 1913, l, 1396.

The compression of the abdominal aorta. FELICE LA TORRE. *Ginec. minore*, 1913, vi, 65.

Obliteration of the superior vena cava. HEBARD. *Gaz. d. Hôp., Par.*, 1913, lxxxvi, No. 87.

Wieting's operation. NASSETI. *Clin. chir., Milano*, 1913, xxi, No. 7.

Vessel suture with measures for widening the lumen of the vessels, and its use in operations in blood vessels on the human subject. DOBROVOLSKAIA. *Russk. Vrach*, 1913, xii, 938.

Ruotte's operation. SIMON. *Berl. klin. Wchnschr.*, 1913, l, 1501.

Transplantation of blood vessels. CHARBONNEL. *Gaz. hebdom. d. sc. med. de Bord.*, 1913, xxxiv, No. 31.

The technique of intravenous administration. BERLIN. *Denver Med. Times*, 1913, xxxiii, 43.

Hodgkin's disease. LAGRIGNON. *J. de Med. et de Chir. de Montreal*, 1913, viii, No. 6.

On lymphogranulomatosis and its relation to other systematized lesions of the hæmopoetic system. H. GUGGENHEIM. *Thèse de doct., Par.*, 1913. [648]

Simultaneous occurrence of cancer and tuberculosis of an axillary lymph-gland. PIERRE NADAL. *Bull. et mém. Soc. anat. de Par.*, 1913, lxxxviii, 354.

A case of lymphangioma circumscriptum. PAUL E. BECHET. *J. Am. M. Ass.*, 1913, lxi, 333.

Injuries of the thoracic duct in operations in the left supraclavicular region. W. M. NASAROFF. *Arb. d. chir. Klin., Prof. W. A. Oppel, Med. Akad. z. St. Petersburg*, 1913, iv, 125.

An acid-fast bacillus from a case of ulcerated throat. C. SHEARMAN. *Australas. M. Gaz.*, 1913, xxxiv, 95.

Gas bacillus infection. D. GUTHRIE. *Penn. M. J.*, 1913, xvi, 863.

Bacterium lactis aerogenes causing fatal septicæmia. HIRSCHBRUCH and ZIEMANN. *Zentralbl. f. Bakteriolog. Parasitenk. u. Infektionskrankh.*, 1913, lxx, 281.

An unusual case of septicopyæmia. W. B. COFFEY, G. R. CARSON and W. T. CUMMINS. *N. Y. M. J.*, 1913, xcvi, 377.

A case of streptococcosis, with a survey of streptococcoses. W. E. BROTHURUS. *Duodecim.*, 1913, No. 6, 1.

Biology of the gonococcus; its importance in gynecology and obstetrics. CHIRCHOFF. *Novoe v med.*, St. Petersburg, 1913, Nos. 13-14.

Importation of cutaneous germs by the knife. ALFRED STEINEGGER. *Zentralbl. f. Chir.*, 1913, xl, 1033.

Surgical Therapeutics

Distribution and excretion of urotropine in the human body and its relation to the differential diagnosis of hydrocephalus, according to Ibrahim. W. USENER. *Ztschr. f. Kinderh.*, 1913, viii, 111.

Unfavorable effects of hexamethylenetetramin (urotropine). WILHELM CUNTZ. *München. med. Wchnschr.*, 1913, lx, 1656.

An experimental study of sodium bicarbonate and other allied salts in shock. SEELIG, TIERNEY and RODENBAUGH. *Am. J. M. Sc.*, 1913, cxlvi, 157.

Experimental tests of hormonal. L. SCHLAGINTWEIT. *Arch. Internat. de pharmacod. et de therap.*, 1913, xxiii, 77.

The effect of morphine on the circulation. E. ANDERES. *Arch. f. exp. Path. u. Pharmak.*, 1913, lxxii, 331.

Influence of raw paraffin oil on the growth of epithelium. FR. ESSLINGER. *Beitr. z. klin. Chir.*, 1913, lxxxv, 715.

Chemotherapeutic experiments upon cancerous subjects by the aid of selenium-iodine-methylene blue. A. BRAUNSTEIN. *Berl. klin. Wchnschr.*, 1913, l, 1102.

Injections of insoluble radium sulphate in inoperable cancers. LEDOUX-LEBARD. *Arch. d'électric. méd., Bordeaux*, 1913, xxi, No. 363.

The influence of copper upon the growth of mouse carcinoma. A. J. GELARIE. *Brit. M. J.*, 1913, ii, 213.

The intravenous employment of camphor. W. WEINTRAUD. *Deutsche med. Wchnschr.*, 1913, xxxix, 1352.

Some notes on a new guaiacol chlor-iodide compound in the treatment of various conditions. JOHN MABERLY. *Lancet, Lond.*, 1913, clxxxv, 282.

The present status of bismuth paste treatment of suppurative sinuses and empyema. EMIL G. BECK. *Tr. Internat. Cong. Med., Lond.*, 1913, Aug. [648]

Noviform in the treatment of wounds. SPECK. *München. med. Wchnschr.*, 1913, lx, No. 34.

Treatment of wounds with mastisol and "mechanical asepsis" by Dettingen's method. HANASIEWICZ. *Wien. med. Wchnschr.*, 1913, lxii, No. 35.

Some dangers from hydrate of chloral. T. D. CROTHERS. *Med. Council*, 1913, xviii, 290.

The anatomical and clinical relations of the sphenoidal sinus to the cavernous sinus and the nerve stems of the oculomotor, trochlear, trigeminal, abducens and vidianus nerves. GREENFIELD SLUDER. *Arch. f. Laryngol. u. Rhinol.*, 1913, xxvii, 369.

Electrology

The physical principles involved in X-ray dosage. CHRISTEN. *Strahlentherapie*, 1913, iii, 162.

The correct reading of color changes in X-ray dosage. G. BUCKY. *Strahlentherapie*, 1913, iii, 172.

The radiochromoscope; an instrument for measuring exact X-ray dosage. T. NOGIER. *Strahlentherapie*, 1913, iii, 165.

Secondary rays originating in the animal tissues. S. RUSS. *Strahlentherapie*, 1913, iii, 308.

The radiograph in relation to the diagnosis and treatment of gastric and intestinal lesions. H. P. COLE. *Atlanta J.-Rec. Med.*, 1913, lx, 197.

The early use of the röntgen ray in the study of the alimentary canal. W. B. CANNON. *Tr. Am. Röntg. Ray Soc.*, Boston, 1913, Oct. [648]

Diagnostic mistakes occasioned by faulty X-ray pictures. E. B. H. VAN LIER. *Ztschr. f. Röntgenk.*, 1913, xv, 205.

The statistics of the X-ray examination for stone in the urinary tract. C. T. HOLLAND. *Tr. Internat. Cong. Med.*, Lond., 1913, Aug. [649]

Stereo-röntgenographic determination of the position of foreign bodies. VON HOLST. *Russk. Vrach*, St. Petersburg, 1913, xii, 800.

New method of external application of radium. VALLET. *Presse méd.*, Par., 1913, xxi, No. 69.

Effect of radio-active substances and radiations upon normal and pathological tissues. W. S. LAZARUS-BARLOW. *Tr. Internat. Cong. Med.*, Lond., 1913, Aug. [649]

Modern röntgen therapy. MEYER. *Deutsche med. Wchnschr.*, 1913, xxxix, No. 31.

Some remarks on radiotherapy. H. W. REYNOLDS. *So. African M. Rec.*, 1913, xi, 347.

Progress of radium-therapy. SAUBERMANN. *Arch. Röntg. Ray*, 1913, xviii, 98. [649]

Theoretical and practical contributions on röntgenotherapy. ERNST HOLZBACH. *Strahlentherapie*, 1913, iii, 279.

Röntgenotherapy in measured massive doses. LANGE. *J. Am. M. Ass.*, 1913, lxi, 556. [650]

Theory and practice of radium and mesothorium treatment. A. STICKER. *Strahlentherapie*, 1913, iii, 1.

Radium in malignant disease. R. ABBE. *Tr. Internat. Cong. Med.*, Lond., 1913, Aug. [650]

Treatment by radiotherapy of some cases of sarcoma and malignant tumors diagnosed clinically. LABEAU. *Gaz. hebdom. d. sc. méd. de Bordeaux*, 1913, xxxiv, No. 34.

Experiences with radium treatment of malignant tumors. ALFRED EXNER. *Wien. klin. Wchnschr.*, 1913, xxvi, 1203.

X-ray treatment of malignant tumors and its combination with other methods of treatment. CHRISTOPH MÜLLER. *Strahlentherapie*, 1913, iii, 177.

The combined chemo- and röntgenotherapy of malignant tumors. LUDWIG SEELIGMANN. *Deutsche med. Wchnschr.*, 1913, xxxix, 1310.

The influence of röntgen rays upon malignant tumors. MAX LEVY-DORN. *Strahlentherapie*, 1913, iii, 210.

Radiotherapeutic treatment of tumors. S. LÖWENTHAL. *Berl. klin. Wchnschr.*, 1913, l, 1519.

The healing process of osteosarcoma under the influence of the röntgen rays. GEORGE E. PFAHLER. *J. Am. M. Ass.*, lxi, 547.

Radiotherapy of carcinomata. PAUL LAZARUS. *Berl. klin. Wchnschr.*, 1913, l, 1304.

What can be done in cancer with röntgen rays? WM. ALLEN PUSEY. *J. Am. M. Ass.*, 1913, lxi, 552. [650]

Treatment of cancer by radium. BAYET. *J. med. de Brux.*, 1913, xxiii, No. 32.

Mesothorium in the treatment of cancer in Germany. GUNSETT. *Arch. d'électric. méd.*, Bordeaux, 1913, xxi, No. 363.

Technique of radiotherapy of cancer. BUMM and VOIGTS. *München med. Wchnschr.*, 1913, lx, No. 31.

Effect of radiotherapy and intravenous chemotherapy on inoperable cancer of the uterus. SEELIGMANN. *München. med. Wchnschr.*, 1913, lx, No. 34.

Effect of radiotherapy and intravenous chemotherapy on inoperable uterine cancer. KLOTZ. *München. med. Wchnschr.*, 1913, lx, No. 31.

Deep radiotherapy. HEIMANN. *Strahlentherapie*, 1913, iii, No. 2.

Röntgen technique of deep therapy. A. F. HOLDING. *Tr. Röntg. Ray Soc.*, Boston, 1913, Oct. [651]

Results obtained with deep radiotherapy. WEITZEL. *Strahlentherapie*, 1913, iii, No. 2.

Results of treatment with X-rays. PETERSEN. *Zentralbl. f. Chir.*, 1913, xl, 1402.

Late injury of the skin and internal organs following X-ray treatment. H. E. SCHMIDT. *Deutsche med. Wchnschr.*, 1913, xxxix, 1553.

Explanation of death caused by X-rays. P. FRAENCKEL and H. MARX. *Arch. f. Kriminal-Anthropol. u. Kriminalist.*, 1913, liv, 103.

Accidents from electricity. F. FRISCHL. *Wien. klin. Wchnschr.*, 1913, xxvi, 1430.

Clinical contributions on injuries by electricity. GOTTLIEB MALÝ. *Deutsche Ztschr. f. Nervenhe.*, 1913, xlv, 366.

Heliotherapy. AIMES. *Montpellier med.*, 1913, xxxvii, No. 23.

Heliotherapy. GUGE. *Deutsche Ztschr. f. Chir.*, 1913, cxxiii, Nos. 5-6.

Remarks on the question of heliotherapeutics. G. A. GUYE. *Deutsche Ztschr. f. Chir.*, 1913, cxxiii, 608.

Military and Naval Surgery

Military surgery. GUSTAVUS M. BLECH. *Am. J. Surg.*, 1913, xxvii, 309.

The Red Cross; notes on war surgery. SLAJMER. *Srpski arh. za celok. lek.*, Beograd, 1913, xix, No. 233.

The Red Cross; notes on war surgery. BOUDISSAV-LEVITCH. *Srpski arh. za celok. lek.*, Beograd, 1913, xix, No. 234.

The limits of conservative treatment in military surgery. KLAPP. *Med. Klin.*, Berl., 1913, ix, 1326.

Surgical observations at the military hospital at Batoum. FROLOFF. *Voenno-med. J.*, St. Petersburg, 1913, ccxxxvii, No. 4.

Periostitis from over-exertion and spontaneous fractures in the army. W. WOLF. *Deutsche mil.-ärztl. Ztschr.*, 1913, xlii, 548. [651]

Experiences with the mastisol bandage in the Servian-Turkish war. STIERLIN and VISCHER. *Cor.-Bl. f. schweiz. Ärzte*, 1913, xliii, 688. [651]

GYNECOLOGY

Uterus

Surgical anatomy of the pelvic uterus in the female of the human species. E. PAPIN. Arch. mens. d'obst. et de gynec., 1913, ii, 1.

Are the uterus and its adnexa suspended or supported? JACOBS. Gynecologie, Par., 1913, xvii, No. 6.

The biological and biochemical function of the endometrium. RIDDLE GOFFE. Internat. Cong. Med., Lond., 1913, Aug.

Carcinoma of the cervix of the uterus. KELLY and NEEL. Bull. Johns Hopkins Hosp., 1913, xxiv, 231. [652]

Cure of carcinoma as a result of bioscopic test curettement. STRATZ. Zentralbl. f. gynec., 1913, xxxvii, No. 31.

Carcinoma of the uterus treated by the Percy cautery method, with autopsy. F. M. LOOMIS. Physician & Surg., 1913, xxxv, 350.

Effect of mesothorium and X-rays on carcinoma of the uterus and ovaries. HAENDLY. Strahlentherapie, 1913, iii, No. 2.

Results obtained with X-ray treatment of carcinoma of the uterus, ovaries and mammæ. G. KLEIN. Deutsche Gesellsch. f. Gynäk., Halle, 1913, May. [652]

The histology of cancer of the uterus. LIEGNER. Beitr. z. Geburtsh. u. Gynäk., 1913, xviii, No. 3.

Cystoscopic examinations in cancer of the cervix of the uterus. HARTMANN. Paris méd., 1913, No. 22, 523.

The results of mesothorium treatment in cancers. A. PINKUSS. Berl. klin. Wchnschr., 1913, l, 1105. [652]

Comparative study of methods of operation for cancer of the uterus and their results. OTT. Russk. Vrach, St. Petersburg, 1913, xii, No. 32.

The treatment of uterine cancer in its very first stages. NEUWIRTH. Zentralbl. f. Gynäk., 1913, xxxvii, No. 33.

Malignant degeneration of chorionic villi extending into the blood circulation; a contribution to malignant chorio-epithelioma. NAGY. Arch. f. Gynäk., 1913, c, No. 2.

Endothelioma of the uterus of traumatic origin, causing complete rotation of the organ on its transverse axis. CURTIS and VANVERTS. L'écho med. du Nord, Lille, 1913, xvii, No. 32.

A rare case of total sarcomatosis of the uterus. CONSTANTINI. Clin. chir., Milano, 1913, xxi, No. 7.

The question of cystic degeneration of uterine myomata. E. GUNAKOFF. Ztschr. f. Geburtsh. u. Gynäk., 1913, xxviii, 715. [653]

Many-celled myomata and myosarcomata of the uterus. RAAB. Arch. f. Gynäk., 1913, c, No. 2.

Experiences with the X-ray in the treatment of hæmorrhagic metropathies and myomas. LANGE. München. med. Wchnschr., 1913, lx, 1740. [653]

Axial torsion of the myomatous uterus. POTH. Zentralbl. f. Gynäk., 1913, xxxvii, No. 31.

Mesothorium in the treatment of hæmorrhagic metropathies and of myomata. A. PINKUSS. Deutsche med. Wchnschr., 1913, xxxix, 1041. [653]

The histopathology of the Fallopian tube in uterine fibromyomata. MAUGERI. Ann. de ostet. e ginec., Milano, 1913, xxxv, No. 7.

Interstitial uterine fibroma and cancer of the cervix. JACOBS. Bull. Soc. belge de gynec. et d'obst., 1913, xxiv, 279.

Hæmorrhages of the menopause and cancer. ANDRÉ CROTTI. Ohio St. M. J., 1913, ix, 370.

Uterine sclerosis and its connection with uterine hæmorrhages. F. W. BUKOJEMSKY. Arch. f. Gynäk., 1913, xcix, 463. [654]

Chronic parametritis and displacements. ZIEGENSPECK. Deutsche Gesellsch. f. Gynäk., Halle, 1913, May. [654]

The operative treatment of chronic inflammatory infiltrations of the pelvic basis, with special consideration of posterior parametritis. FALGOWSKI. Gynäk. Rundschau, 1913, vii, No. 15.

Mud and mineral baths during menstruation. A. A. RUSSAKOVA-SWOWITSCH. Ztschr. f. Geburtsh. u. Gynäk., 1913, xxviii, 783. [654]

Partial muscular atrophy in myopathies. ROSE. Semaine méd., Par., 1913, xxxiii, No. 33.

Leukoplakia uteri. THOMPSON F. SWEENEY. Am. J. Obst., N. Y., 1913, lxviii, 236. [654]

Reflex vomiting and uterine displacement a clinical study. T. M. WEST. Va. M. Semi-Month., 1913, xviii, 226.

Associated occurrence of uterovaginal prolapse; hysterocolopexy and its indications. LENORMANT. Gynecologie, Par., 1913, xvii, No. 6.

Exohysteropexy or suspension of the uterus in hammock form as a treatment of prolapse of the genitalia. DELASSUS. Semaine gynec., Par., 1913, 245.

Elimination of the danger of peritonitis in the operative treatment of rupture of the uterus and of perforating injuries of the uterus. WALTER SIGWART. Arch. f. Gynäk., 1913, c, 196.

The indications for and technique of defundatio uteri. A. RIECK. Frauenarzt, 1913, xxviii, 242. [654]

Adnexal and Periuterine Conditions

Giant ovary. S. POZZI and ROUHIER. Bull. et mém. Soc. anat. de Par., 1913, lxxxviii, 369.

Internal secretion of ovaries and its relation to the lymphocytes. F. HEINMANN. Ztschr. f. Geburtsh. u. Gynäk., 1913, lxxiii, 538. [655]

A clinical and anatomical pathological contribution to the study of hæmorrhages of ovarian origin. BERTINO. Ginecologia, Milano, 1913, x, No. 4.

Sarcoma developing within a teratoma of the ovary with metastases in the great omentum. H. KLOSS. Zentralbl. f. allg. Pathol. u. pathol. Anat., 1913, xxiv, 482. [655]

Ovarian teratomata. CHARLES STANLEY WHITE. Am. J. Obst., N. Y., 1913, lxviii, 236.

Carcinomatous degeneration of ovarian cysts. ULESKO-STROGONOFF. Russk. Vrach, St. Petersburg, 1913, xii, 604. [655]

Suppurative dermoid cyst of the left ovary as a complication of puerperium. BERTINO. Ginecologia, Milano, 1913, x, No. 5.

The disadvantages of the conservative surgery of ovarian cysts. SILHOL. Arch. mens. d'obst. et de gynec., 1913, ii, 338.

Experimentally obtained results of radio-active treatment of the ovaries. LACASSAGNE. Ann. de gynec. et d'obst., Par., 1913, x, Aug.

The removal of blood from the peritoneal cavity following rupture of the tube. BAISCH. Monatschr. f. Geburtsh. u. Gynäk., 1913, xxxvii, 714. [655]

Chorio-epithelioma of the tube. ALPHONSE HUGUIER and LORRAIN. Bull. et mém. Soc. anat. de Par., 1913, lxxxviii, 343.

Three cases of tuberculosis of the adnexa. DE ROUVILLE. *Montpellier med.*, 1913, xxxvii, No. 30.

The conservative surgical therapeutic procedure in the treatment of tuberculosis of the adnexa. PATEL and OLIVIER. *Rev. de gynéc. et de chir. abdom.*, Par., 1913, xxi, No. 1.

Affections of the adnexa; inflammations and tubal pregnancy. W. HANNES. *Ergebn. d. Chir. u. Orthop.*, 1913, vi, 609. [655]

Fibromyomata of the broad ligament. ALFIERI. *Ginecologia*, Milano, 1913, x, No. 3.

One hundred cases of ventrofixion of the round ligaments after my own method and 100 operations after the method of Alexander-Adams with sutures buried as a matter of principle and without a single recurrence. RISSMANN. *Ztschr. f. Geburtsh. u. Gynäk.*, 1913, lxxiii, No. 3.

External Genitalia

Vaginal injections. PAUL DALCHÉ. *Rev. prat. d. mal. d. organ. génito-urin.*, 1913, x, 275.

Vaginal bacteria and endogenous infection. O. BONDY. *Ztschr. f. Geburtsh. u. Gynäk.*, 1913, lxxiii, 604. [656]

A case of primary cancer of the vagina associated with leucoplasia. LÖHNBERG. *Ztschr. f. Geburtsh. u. Gynäk.*, 1913, lxxiii, No. 3.

Cysts of the vagina. BATALINE. *Sibirsk. Vrach. Gaz.*, 1913, vi, No. 21.

Radical treatment of vaginal hydrocele by the inguinal path of access. GOMAIN. *Lyon chir.*, 1913, x, No. 2.

Vaccine therapy in the treatment of vulvo-vaginitis. W. R. JACK. *Glasgow M. J.*, 1913, lxxx, 84. [656]

The iodine treatment of gonorrhœa in the female. O. HOFMANN. *Interst. M. J.*, 1913, xx, 733. [657]

Prolapse of the mucous membrane of the urethra in girls (intussusceptive mucosæ urethræ). M. G. KISCHNIR. *Russk. Vrach. St. Petersburg.*, 1913, xii, 1038.

Lacerations of the perineum: prevention and treatment. H. E. PRICE. *Ellingwood's Therapeutist*, 1913, vii, 267.

Miscellaneous

Address in gynecology. THOMAS S. CULLEN. *Canad. M. Ass. J.*, 1913, iii, 658. [657]

Points and pitfalls in gynecological diagnosis. JOHN BENJAMIN HELLER. *Practitioner*, Lond., 1913, xci, 157.

Present status of radiotherapy in gynecology. ENGELHORN. *Strahlentherapie*, 1913, iii, No. 2.

Röntgenotherapy in gynecology. GEORGE E. PFAHLER. *Tr. Am. Röntg. Ray Soc.*, Boston, 1913, Oct. [657]

Röntgenotherapy in gynecology. KIRSTEIN. *Gynäk. Rundschau*, 1913, vii, No. 15.

Mesothorium in gynecology. SIGWART and HÄNDLY. *Med. Klin.*, Berl., 1913, ix, No. 33.

Technique of gynecological mesothorium treatment. GAUSS. *Strahlentherapie*, 1913, iii, No. 2.

Mesothorium treatment of genital cancer. JUNG. *Strahlentherapie*, 1913, iii, No. 2.

Effect of röntgen and mesothorium rays on tumors of the genital organs. KROEMER. *Strahlentherapie*, 1913, iii, No. 2.

The cystoscopic diagnosis of a ureteral calculus and its removal by the vaginal route. F. HEINSIUS. *Ztsch. f. Geburtsh. u. Gynäk.*, 1913, lxxiii, 441. [657]

A case of acute retention of the urine in gynatresia. H. LOHNSTEIN. *Ztschr. f. Urol.*, 1913, vii, 630.

Congenital anomalies in the urinary apparatus in woman. M. PIETKIEWICZ. *Przegl. i ginec.*, Washawa, 1913, viii, 343.

External female pseudohermaphroditism. KÜSTNER. *Ztschr. f. Geburtsh. u. Gynäk.*, 1913, lxxiii, No. 3.

The modern diagnosis and treatment of gynecological and obstetrical patients with syphilis. J. B. SQUIER. *N. Y. M. J.*, 1913, xcvi, 357. [658]

Bacteriological control of sepsis during gynecological laparotomies. W. SIGWART. *Arch. f. Gynäk.*, 1913, xcix, 284. [658]

Relations between affections of the veins and the female genitalia. RUD. TH. JASCHKE. *Zentralbl. f. d. Grenzgeb. d. Med. u. Chir.*, 1913, xvii, 115.

Relations of inflammatory conditions of the colon to the female genitalia and to functional neuroses. E. OPITZ. *Ztschr. f. Geburtsh. u. Gynäk.*, 1913, lxxiii, 362.

The surgical treatment of pelvic thrombosis of septic origin. HENRY JELLETT. *Surg., Gynec. & Obst.*, 1913, xvii, 147. [658]

Associated occurrence of tubercular and neoplastic genitalia. PAMPININI. *Ann. di ostet. e ginec.*, Milano, 1913, xxxv, No. 7.

Basedow's disease and genital organs. LAMPÉ. *Deutsche Gesellsch. f. Gynäk.*, Halle, 1913, May. [659]

The changes in the blood during menstruation. V. CANTONI. *Arch. f. Gynäk.*, 1913, xcix, 541.

Precocious menstruation. GENGENBACH. *J. Am. M. Ass.*, 1913, lxi, 563. [659]

The demonstration of menstrual blood by the glyco-geniodin reaction. F. DYRENFURTH. *Ztschr. f. Med.-Beamte*, Berl., 1913, xxvi, 452.

Passionate phenomena; hyperemia and hæmorrhages of the female genitalia following subcutaneous injection of ovarian or placental extract. BERNARD ASCHNER. *Arch. f. Gynäk.*, 1913, xcix, 534.

The drop method for the injection of saline solutions into the rectum in gynecology. KOUSKOVA-OUSSOVA. *J. akush. i jensk. boliez.*, St. Petersburg, 1913, xxviii, Nos. 7-8.

OBSTETRICS

Pregnancy and Its Complications

The elastic area in the isthmus of the uterus as a positive and early sign of uterine pregnancy. LOUIS J. LADINSKI. *Am. J. Obst., N. Y.*, 1913, lxviii, 210. [660]

The determination of the duration of pregnancy on the basis of histological placental findings and the possible practical utility of these findings. A reply to Peters'

article of the same title. J. SCHOTTLENDER. *Zentralbl. f. Gynäk.*, 1913, xxxvii, 806. [660]

Nitrogen metabolism during pregnancy. S. A. GAMMELTOFT. *Skandinav. Arch. f. Physiol.*, 1913, xxviii, 325. [660]

The cholesterol content of the bile during pregnancy. J. W. MCNEE. *Deutsche med. Wchnschr.*, 1913, xxxix, 994. [660]

A case of partial retroflexion of the pregnant uterus. FONYO. *Zentralbl. f. Gynäk.*, 1913, xxxvii, No. 34.

Uterine myomata complicating pregnancy. W. T. CHENHALL. *Australas. M. Gaz.*, 1913, xxxiv, 122.

Uterine fibroids and pregnancy. W. TRETOWAN. *Australas. M. Gaz.*, 1913, xxxiv, 119.

The pernicious vomiting of pregnancy. R. A. KINGMAN. *Am. Med.*, 1913, viii, 519. [660]

Mitral stenosis complicating pregnancy. S. E. MUNSON. *Illinois M. J.*, 1913, xxiv, 114.

Patent ductus arteriosus; report of a case complicated by pregnancy. LEO BROOKS ROSENTHAL. *Am. J. Obst.*, N. Y., 1913, lxviii, 252. [661]

Frequency and significance of cardiac disease during pregnancy. PANKOW. *Deutsche Gesellsch. f. Gynäk.*, Halle, 1913, May. [661]

Addison's disease and pregnancy. VOGT. *München. med. Wchnschr.*, 1913, lx, No. 33.

Cystic kidneys and pregnancy. F. HEINSIUS. *Ztschr. f. Geburtsh. u. Gynäk.*, 1913, lxxiii, 429.

Pyelonephritis in pregnancy. CHAUFFARD. *J. d. Prat.*, Par., 1913, xxvii, No. 34.

Hæmorrhages in pregnancy. DAVERNE. *Année méd.*, Caen., 1913, xxxviii, 273.

The surgical treatment of bacillus coli communis infection complicating pregnancy with report of cases. E. P. DAVIS. *Tr. Internat. Cong. Med.*, Lond., 1913, Aug. [662]

Ectopic pregnancy in the ovarian ligament; a contribution to the anatomical diagnosis of advanced cases. E. ENGELKING. *Monatschr. f. Geburtsh. u. Gynäk.*, 1913, xxxvii, 740. [662]

Clinical data on extra-uterine pregnancy. CHOMIAKOVA-BOUSLOVA. *J. akush. i jensk. boliez.*, St. Petersburg, 1913, xxviii, Nos. 7-8.

Extra-uterine pregnancy. R. C. FRAVEL. *Va. M. Semi-Month.*, 1913, xviii, 220.

Treatment of extra-uterine gravidity. E. FALK. *Arch. f. Gynäk.*, 1913, xcix, 638.

Tubal or extra-uterine pregnancy. J. HUGH CARTER. *South. M. J.*, 1913, vi, 521.

Tubal pregnancy. HARTMANN. *Nord. med. Arch.*, Stockholm, 1913, xlvi (Chir. F. 1).

Diagnosis of pregnancy developed in rudimentary horn of the uterus. BRUNO. *J. akush. i jensk. boliez.*, St. Petersburg, 1913, xxviii, Nos. 7-8.

The diagnosis and treatment of eclampsia. G. W. KOSMAK. *Merck's Arch.*, 1913, xv, 243.

The indications for abdominal Cæsarean section. REUBEN PETERSON. *Surg., Gynec. & Obst.*, 1913, xvii, 198. [662]

Statistics on supra-symphyseal transperitoneal Cæsarean section. G. RONCAGLIA. *Ann. di ostet. e ginec.*, 1913, xxxv, 206.

The present technique of abdominal Cæsarean section in France. JEANNIN. *Presse méd.*, Par., 1913, xxi, No. 65.

Cæsarean section with hysterectomy in cases of positive infection. J. F. BALDWIN. *N. Y. M. J.*, 1913, xcvi, 372. [662]

Two unusual cases of ectopic pregnancy, one a triplet. J. F. BALDWIN. *J. Am. M. Ass.*, 1913, lxi, 392. [663]

Early miscarriage. WALLICH. *Rev. de gynéc. et de chir. abdom.*, Par., 1913, xxi, No. 1.

Bacteriological examination in the treatment of abortion. A. SCHERER. *Orvosi hetil.*, Budapest, 1913, lvii, 337.

The artificial interruption of pregnancy and sterilization in one session by the abdominal route. H. SELHEIM. *Monatschr. f. Geburtsh. u. Gynäk.*, 1913, xxxviii, 166.

Labor and Its Complications

Present views on the management of normal labor. CHARLES F. DENNY. *St. Paul M. J.*, 1913, xv, 381.

Difficult labor. H. C. CLARK. *Ky. M. J.*, 1913, xi, 740.

Prolonged precipitate parturition due to disengagement of the disproportionate head. A. E. GALLANT. *Med. Rec.*, 1913, lxxxiv, 337. [663]

A case of complete spontaneous rupture of the uterus at the moment of delivery. PETROPAVLOVSKY. *Vrach. Gaz.*, St. Petersburg, 1913, xx, No. 30.

Uterine rupture following the use of pituglandol. ESPENT. *München. med. Wchnschr.*, 1913, No. 32.

Delivery in total paralysis of the body. M. BOGDANOWITSCH. *Zentralbl. f. Gynäk.*, 1913, xxxvii, 809. [663]

Subcutaneous symphyseotomy. DE BOVIS. *Semaine méd.*, Par., 1913, xxxiii, No. 33.

Puerperium and Its Complications

A case of puerperal tetanus with recovery. WERNER. *Monatschr. f. Geburtsh. u. Gynäk.*, 1913, xxxvii, 671. [664]

A case of puerperal sepsis cured by operation. BRIX. *München. med. Wchnschr.*, 1913, lx, 1325.

An unusual case of extension necrosis of the puerperal uterus. A. VON REDING. *Cor.-Bl. f. Schweiz. Ärzte.*, 1913, xliii, 651.

Emptying the uterus as a method of treatment of puerperal eclampsia. REUBEN PETERSON. *Am. J. Obst.*, N. Y., 1913, lxviii, 201. [664]

The medical versus the surgical treatment of puerperal eclampsia. E. G. ZINKE. *N. Y. St. J. M.*, 1913, xiii, 422. [664]

On the management of the interior of the uterus in post-abortal and post-partial infection. J. POLAK. *Tr. Internat. Cong. Med.*, Lond., 1913, Aug. [664]

Peroneus paresis post-partum. C. STAUDE. *Monatschr. f. Geburtsh. u. Gynäk.*, 1913, xxxvii, 611. [665]

Miscellaneous

Beriberi in infancy. Poisoning of the nursing by the milk of a mother affected with beriberi. Based on the work of American physicians in the Philippines. KRONECKER. *Allg. med. Zentralztg.*, 1913, lxxxii, 404.

A study of stillbirths. L. W. THOMAS. *N. Y. M. J.*, 1913, xcvi, 413.

Fœtal hormones. B. WOLFF. *Habilitationschrift*, Rostock, 1913. [665]

The use of fœtal serum to cause the onset of labor. A. F. ROUGHY. *M. S. J.*, Calcutta, 1913, x, 109. [666]

Intra-uterine rupture of the fœtal liver. DIETRICH. *Monatschr. f. Geburtsh. u. Gynäk.*, 1913, xxxvii, 868. [666]

Organic specificity of the pregnancy ferments in relation to the placenta. G. PLOTKIN. *München. med. Wchnschr.*, 1913, lx, 1942.

On some phosphatids derived from the human placenta. C. SAKAKI. *Biochem. Ztschr.*, 1913, liv, 1.

Diagnosis of retro-placental hæmorrhage. BONNET-LABORDERIE. *J. d. sc. méd. de Lille*, 1913, xxxvi, No. 30.

Care of the umbilical stump. FRED L. ADAIR. *J. Am. M. Ass.*, 1913, lxi, 537. [666]

Sacral anæsthesia. S. SCHLIMPERT. *Deutsche Gesellsch. f. Gynäk.*, Halle, 1913, May.

The relations between menstruation and nursing the child. D. TIBONE. *Rassegna d'ostet. e ginec.*, Napoli, 1913, xxii, 129.

The care of the nipple during pregnancy. KRÜGER. *Monatschr. f. Geburtsh. u. Gynäk.*, 1913, xxxvii, 867. [667]

The clinical significance of the urine in pregnancy. HAROLD C. BAILEY. *Am. J. Obst., N. Y.*, 1913, lxviii, 252 [667]

The influence of the thyroid glands on pregnancy and lactation. W. M. THOMPSON. *Surg., Gynec. & Obst.*, 1913, xvii, 225. [667]

The biological diagnosis of pregnancy. POLANO. *Monatschr. f. Geburtsh. u. Gynäk.*, 1913, xxxvii, 857. [667]

The serodiagnosis of pregnancy. HENRY SCHWARZ. *J. Am. M. Ass.*, 1913, lxi, 484. [667]

Can Abderhalden's dialization method be used in differential diagnosis? E. SCHIFF. *Deutsche Gesellsch. f. Gynäk.*, Halle, 1913, May. [667]

The applicability of Abderhalden's reaction for the serum diagnosis of pregnancy. F. MACCABRUNI. *München. med. Wchnschr.*, 1913, lx, 1259. [668]

Diagnostic value of Abderhalden's serum reaction. BRUCK. *München. med. Wchnschr.*, 1913, No. 32. [668]

Clinical observations on Abderhalden's reaction. JAWORSKI. *Gynäk. Rundschau*, 1913, vii, No. 15. [668]

The therapeutic use of the normal serum of pregnancy. A. MAYER. *München. med. Wchnschr.*, 1913, lx, 1411. [668]

Pituitrin in obstetrics. JENNINGS C. LITZENBERG. *St. Paul M. J.*, 1913, xv, 399. [668]

A case of rupture of the uterus following the administration of pituitrin. E. HERZ. *Zentralbl. f. Gynäk.*, 1913, xxxvii, 720. [668]

Experiences with pituglandol in obstetrics. A. FUCHS. *Ztschr. f. Geburtsh. u. Gynäk.*, 1913, lxxiii, 517. [668]

The modification of the hæmoglobin catalyzer during pregnancy. ERNST ENGELHORN. *München. med. Wchnschr.*, 1913, lx, 1195. [668]

The relation of the cervix to sterility and pregnancy. M. F. GOLDBERGER. *Internat. J. Surg.*, 1913, xxvi, 269. [668]

Gonorrhœa in relation to pregnancy and the puerperal period. A. S. JAEGER. *J. Indiana St. M. Ass.*, 1913, vi, 353. [668]

Retrospect of 510 obstetrical cases. J. B. CRAMMER. *South. M. J.*, 1913, vi, 543. [668]

Experiences in a private obstetrical practice extending over 25 years. HENRY J. KREUTZMANN. *Monatschr. f. Geburtsh. u. Gynäk.*, 1913, xxxviii, 260. [668]

A review of obstetrical literature of the third quarter of the year 1912. K. FRANKENSTEIN. *Fortschr. d. Med.*, 1913, xxxi, 958. [668]

Radical and conservative management of some obstetric problems. ROSCOE D. McMILLAN. *Hosp. Bull. Univ. Md.*, 1913, ix, 100. [668]

GENITO-URINARY SURGERY

Kidney and Ureter

The pathology of the suprarenal capsules. KONRAD HELLY. *München. med. Wchnschr.*, 1913, lx, 1811. [669]

Associated occurrence of heterotopic bone marrow and aberrant tissue of the suprarenal capsule. ALDO BOLAFFI. *Arch. per le sc. med., Torino.*, 1913, xxxvii, 132. [669]

Tumors of the medulla of the suprarenal glands, particularly sympathetic neuroblastoma. HERXHEIMER. *Beitr. z. path. Anat. u. z. allg. Path.*, 1913, lvii, No. 1. [669]

Physiology of kidney secretion. O. COHNHEIM. *Sitzungsber. d. Heidelb. Akad. d. Wissensch. Math.-naturw. Cl.*, 1913, vi, 1. [669]

Radiographical examination of the kidneys. S. P. GRIGORJEW. *Verhandl. d. XII Kong. russ. Chir.*, 1913, xii, 173. [669]

Clinical observations on the influence of the nerves on the secretion of the kidneys. GRASER. *Deutsche Ztschr. f. Nervenhe.*, 1913, xlvii-xlviii, 176. [669]

Anatomical changes in the kidney after ligation of the ureter. M. KAWASOYE. *Ztschr. f. gynäk. Urol.*, 1913, iv, 107. [669]

Experimental data on the influence of the injured kidney on the opposite kidney. ISOBE. *Mitt. a. d. Grenzgeb. d. Med. u. Chir.*, 1913, xxvi, No. 1. [669]

The pathology and treatment of nephrolithiasis. WILHELM KARAO. *Med. Klin., Berl.*, 1913, ix, 1282. [669]

Renal calculus in relation to the kidney and ureter. STEPHEN E. TRACY. *Am. J. Obst., N. Y.*, 1913, lxviii, 201. [669]

Operation of choice in renal calculus. LEGUEU. *Clinique, Par.*, 1913, viii, No. 31. [669]

Movable kidney. C. MACLAURIN. *Australas. M. Gaz.*, 1913, xxxiv, 191. [669]

Bacteriology of the urine in relation to movable kidney. DAVID HADDEN. *Cal. St. J. Med.*, 1913, xi, 326. [669]

Congenital movable kidney. CATHELIN. *Paris méd.*, 1913, No. 37. [670]

Operation for floating kidney. K. VOGEL. *Verhandl. d. Gesellsch. deutscher Naturforsch. u. Ärzte*, 1913, ii, part 2, 156. [670]

Supernumerary kidneys. SUTER. *Folia urol., Leipz.*, 1913, viii, No. 1. [670]

Two congenital renal anomalies. VAN RISSELICK. *Zentralbl. f. Chir.*, 1913, xl, 1296. [670]

Essential hæmaturia, with a report of a case cured by injection of adrenalin through the ureteral catheter. HARVEY MOORE. *Urol. & Cutan. Rev.*, 1913, xvi, 107. [670]

An unusual case of renal hæmaturia; unilateral chronic hæmorrhagic nephritis; decapsulation; apparent cure; recurrence; bilateral involvement; decapsulation of both kidneys six years later. W. G. VINCENT. *Med. Rec.*, 1913, lxxxiv, 106. [670]

On the value of a renal hæmaturia immediately following nephrectomy for tuberculosis. M. PENA. *J. d'Urol.*, 1913, iv, 43. [670]

Unilateral hæmorrhages in nephritis. STRÄTER. *Zentralbl. f. Chir.*, 1913, xl, 1297. [670]

Fibrin detritus in the renal pelvis. N. W. PETROW. *Zentralbl. f. allg. Path. u. path. Anat.*, 1913, xxiv, 633. [670]

Tumor of the left kidney. KIRMISSON. *Clinique, Par.*, 1913, viii, No. 31. [670]

Three unusual cases of renal tumor, with a discussion of the operative treatment of the condition. J. SWIFT JOLY. *Practitioner, Lond.*, xci, 179. [670]

Suppurated polycystic renal tumor associated with marked intra-cystic hæmorrhage. Removal of the same in a woman in a very weak and anæmic state under local anæsthesia; rapid recovery. LE FILLIATRE. *Bull. et mém. Soc. anat. de Par.*, 1913, lxxxvi, 389. [670]

Case of congenital cystic kidney associated with uterine fibroid. R. PETERSON. *Physician & Surg.*, 1913, xxxv, 345. [670]

Functional diagnosis of kidney disease. G. W. McCASKEY. *Lancet-Clin.*, 1913, cx, 164.

The amount of work done by diseased kidneys. Experimental researches. ST. CSERNA and G. KELEMEN. *Biochem. Ztschr.*, 1913, liii, 41.

The question of ascending infection of the kidney and the prevention of the same in implantation of the ureter into the bowel. A. J. ILJIN. *Dissertation*, St. Petersburg, 1913. [670]

Unilateral septic infection of the kidneys. A. P. CONDON. *N. Y. M. J.*, 1913, xcvi, 279. [670]

Purulent pyelitis. LEONARD D. FRESCOLN. *Urol. & Cutan. Rev.*, 1913, xvi, 425.

Unilateral painful chronic nephritis. TODDEL. *Folia urol.*, Leipzig, 1913, viii, No. 1.

Painful chronic nephritis. LE CLERC-DANDOY. *J. med. de Brux.*, 1913, xxiii, No. 31.

Thirty-four cases of chronic nephritis treated operatively since 1901. TH. ROVSING. *Cong. Verhandl. d. Nord. chir. Forening*, Kjøbenhavn, 1913.

Treatment of nephritis. C. A. WILLIAMS. *Hahneman. Month.*, 1913, xlviii, 569.

Perinephritic abscess. STUDEBAKER. *Iowa M. J.*, 1913, xx, 75.

Case of post-operative serous perinephritis. A. BAUER-EISEN. *Ztschr. f. gynäk., Urol.*, 1913, iv, 124.

Renal tuberculosis. RIVERA Y. MOSET. *Rev. de med. y cir. prat.*, Madrid, 1913, xxxvii, No. 1277.

Diagnosis of renal tuberculosis. PUYADE. *Argent. med.* Buenos Aires, 1913, xi, No. 31.

Diagnosis and treatment of tuberculosis of the kidney. PAUCHET. *Bull. méd., Par.*, 1913, xxvii, No. 62.

Localization of renal tuberculosis by radiography. PAPIN. *Arch. urol. clin. de Necker*, 1913, i, 197. [671]

Tuberculosis of the kidney and bladder including urogenital tuberculosis. RUPPRECHT. *München. med. Wchnschr.*, 1913, lx, 1459.

Radiography in renal tuberculosis. LEGUEU. *Clinique, Par.*, 1913, viii, No. 33.

A clinical lecture on tuberculosis of the urinary tract. J. HOWELL EVANS. *Lancet*, Lond., 1913, clxxxv, 273.

Infection of the urinary tract in children by the colon bacillus. J. THOMSON. *Lancet*, Lond., 1913, clxxxv, 467. [671]

Adrenal hypernephroma in the adult female associated with male secondary characters. E. GLYNN and J. T. HEWETSON. *J. Pathol. and Bacteriol.*, 1913, xviii, No. 1. [672]

Pyelography. L. JACHES. *Tr. Am. Röntg. Ray Soc.*, Boston, 1913, Oct. [672]

The technique and accidents of pyelography. LÉGUEU and PAPIN. *Arch. urol. clin. de Necker*, 1913, i, 12. [672]

Kidney surgery. H. HEIDLER. *Prag. med. Wchnschr.*, 1913, xxxviii, 507.

General clinical aspects of surgical kidney. CATHELIN. *Prog. med., Par.*, 1913, xlv, No. 33.

Experiences in renal surgery. G. VON ILLYÉS. *Buda-pest*: Franklin, 1913. [673]

Pyelotomy. ÖLSNER. *Ztschr. f. Urol.*, 1913, vii, 535.

Technique of nephro-, pyelo-, and ureterolithotomy. JOHN H. GIBBON. *Ann. Surg., Phila.*, 1913, lviii, 232. [673]

Nephropexy by means of free transplantation of bands of fascia. CORDUA. *Zentralbl. f. Chir.*, 1913, xl, No. 32.

Renal transplantations. VILLARD and PERRIN. *Lyon chir.*, 1913, x, No. 2.

The present status of renal functional tests with special reference to phenolsulphonephthalein. FROMM and SOUTHWELL. *Albany Med. Ann.*, 1913, xxxiv, 445.

The phenolsulphonephthalein test (Abel and Row-

tree's test). G. MOURIQUAND. *Lyon méd.*, 1913, cxxi, 297.

Functional diagnosis of renal affections. JANOWSKY. *Russk. Vrach.*, St. Petersburg, 1913, xii, 169.

Experimental studies of the diagnosis of kidney function. W. R. BRAIZEW. *Verhandl. d. XII Kong. russ. Chir.*, 1913, xii, 167.

Contribution to the functional diagnosis of the kidney. R. BROMBERG. *Beitr. z. klin. Chir.*, 1913, lxxxv, 411. [673]

The difference between the secretion and the retention of coloring matter in the kidney. GEORGE BÄHR. *Zentralbl. f. allg. Path. u. path. Anat.*, 1913, xxiv, 625.

Calculus anuria. HERESCU. *Spitalul*, Bucarest, 1913, xxxiii, No. 9.

Hydronephrosis produced by experimental ureteral obstruction. G. D. SCOTT. *J. Indiana St. M. Ass.*, 1913, vi, 339. [673]

Gonococcic ureterocystitis, right uropyonephrosis, nephrostomy, left pyonephrosis, posterior pyelotomy, late secondary nephrectomy. Recovery. BOULANGER. *Folia urol.*, Leipzig, 1913, vii, No. 11.

A new ureterocystoscope, arranged for ready exchange of the catheters, with a contribution to asepsis of ureteral catheterization. VOGEL. *Ztschr. f. Urol.*, 1913, vii, No. 8.

Fixation of the ureters into the large intestine. L. LEGUEU. *Gazz. d. osp. e d. clin.*, Milano, 1913, xxxiv, 848.

Bladder, Urethra and Penis

A case of traumatic intraperitoneal rupture of the bladder. BARADOUINE. *Chirurgia*, St. Petersburg, 1913, xxxiii, No. 193.

Study of vesical calculi. OLIVIERA, SOUZA and O. MORENO. *Med. moderna*, 1913, xx, 209.

Modern tendencies in the treatment of vesical calculus. IZQUIERDO SANCHEZ. *Prensa med.*, Havana, 1913, iv, No. 7.

Modern conception of treatment of vesical calculus. CATHELIN. *J. d. Prat.*, Par., 1913, xxvii, No. 32.

The surgical treatment of bladder-stone in children. TRIFILIEFF. *Chirurgia*, St. Petersburg, 1913, xxxiii, No. 193.

Foreign bodies in the bladder and their treatment. LÉGUEU. *Allg. wien. med. Ztg.*, 1913, lviii, 176. [674]

A hairpin in the bladder. LEGUEU. *Rev. prat. d. mal. d. organ. génito-urin.*, 1913, x, 203.

The relief of vesical obstruction in selected cases. H. G. BUGBEE. *N. Y. St. J. M.*, 1913, xiii, 410. [674]

Bladder deformity after ventro-suspension. WELLER VAN HOOK. *Urol. & Cutaneous Rev.*, 1913, xvi, 427.

Electro-coagulation of tumors of the bladder. LÉGUEU. *Arch. urol. clin. de Necker*, 1913, i, 131. [674]

The endovesical treatment of tumors of the bladder. L. CASPER. *Ztschr. f. Urol.*, 1913, vii, 700.

Intravesical treatment of papilloma of the bladder by electrolysis. R. OPPENHEIMER. *Ztschr. f. Urol.*, 1913, vii, 728.

A case of marked secondary hæmorrhage following operation for papilloma of the bladder by high-frequency currents. C. SCHNEIDER. *Ztschr. f. Urol.*, 1913, vii, 638.

A case of leucoplasia of the bladder. AXEL LENDORF. *Hosp-Tid.*, Kjøbenhavn, 1913, lvi, 887.

The etiology and treatment of cystitis in women. F. W. GRIFFITH. *Merck's Arch.*, 1913, xv, 240.

Transformation of a cystic into a glandular cystitis. J. FRANÇOIS. *J. d'urol.*, 1913, iv, 207. [674]

Syphilis of the bladder. A. DREYER. *Dermatol. Ztschr.*, 1913, xx, 477.

Operative treatment of diseases of the neck of the bladder and the posterior urethra. E. WOSSIDLO. *Berl. klin. Wchnschr.*, 1913, l, 1570.

Endovesical and endourethral treatment by high-frequency currents. ROBERT BACHRACH. *Folia urol., Leipz.*, 1913, vii, 685.

Epicystotomy with empty bladder. LASTARIA. *Arch. ital. di ginec., Napoli*, 1913, xvi, No. 7.

Total cystectomy for multiple or infiltrated neoplasms of the bladder. P. HERESCO. *J. d'urol.*, 1913, iv, 169.

Clinical findings relative to operative cystoscopy. LEO. BÜRGER. *Ztschr. f. urol. Chir.*, 1913, i, 419.

Cystoscopy and ureteral catheterization. MOORE. *Clin. Med.*, 1913, xx, 663.

Topography of the bladder with special reference to cystoscopy. V. C. PEDERSEN. *N. Y. M. J.*, 1913, xcvi, 353.

Angioma of the urethra as a cause of grave hæmorrhages. A. WOLFF. *Wien. klin. Wchnschr.*, 1913, xxvi, 1364.

Posterior urethroscopy by Goldschmidt's method. PRIOR. *Hosp-Tid., Kjøbenh.*, 1913, lvi, No. 37.

Internal urethrotomy. R. FRONSTEIN. *Vrach. Gaz., St. Petersburg*, 1913, xx, 925.

Plastic surgery of the male urethra. KLIOUTCHAREFF. *Chirurgia, St. Petersburg*, 1913, xxxiii, No. 193.

Multiple myoma of the penis. A casuistic communication. FRANZ STAVIANICEK. *Ztschr. f. Urol.*, 1913, vii, 635.

Tuberculosis of the penis. J. LEWINSKI. *Dermat. Ztschr.*, 1913, xx, 692.

The treatment of gonorrhœa in the male. DANIEL T. MILLER. *Indianapolis M. J.*, 1913, xvi, 321.

Genital Organs

Disturbances of the development of the testicles in children. HEINRICH VOSS. *Zentralbl. f. allg. Path. u. path. Anat.*, 1913, xxiv, 433.

Treatment of cryptorchism. HANUSA. *Zentralbl. f. Chir.*, 1913, xl, 1411.

Necrosis of the testicle from torsion of the cord; case report and observations. VISCONTINI. *Gaz. d. osp. e d. Clin., Milano*, 1913, xxxiv, No. 100.

Radical cure of malignant tumors of the testicle by extirpation of the juxta-aortic glands. MARAGLIANO. *Rif. med., Naples*, 1913, xxix, Nos. 33-34.

Tuberculosis of the testicle and hæmaturia. HENRY K. MORTON. *Med. Times*, 1913, xli, 237.

Traumatic tuberculosis of the testicles, its interpretation and treatment in respect to medicine and insurance. O. RÖPKE. *Ztschr. f. Versicherungsmed.*, 1913, vi, 161.

Surgical treatment of ectopy of the testicles. BARNABO. *Policlin., Roma*, 1913, sez. chir., xx, No. 8.

The question of reproductive potency in tuberculosis of the epididymis. FÜRBRINGER. *Deutsche med. Wchnschr.*, 1913, xxxix, 1393.

Acute non-gonorrhœal orchitis and epididymitis with special consideration of bacteriological examination. H. STROINK. *Deutsche med. Wchnschr.*, 1913, xxxix, 1551.

The treatment of gonorrhœal complications, especially gonorrhœal epididymitis, by electrargol. JULIUS FÜRTH. *Dermat. Wchnschr.*, 1913, lvi, 689.

Epididymotomy. The radical operative treatment of epididymitis. LAUREN S. ECKELS. *J. Am. M. Ass.*, 1913, lxi, 470. [675]

Connective tissue cysts of the vas deferens. PAOLO FIORI. *Deutsche med. Wchnschr.*, 1913, xxxix, 1145.

The pathogenesis of hydrocele. ZESAS. *Zentralbl. f. Chir.*, 1913, xl, No. 33.

Hydrocele and hematocele. OKINCZYC. *Prog. med., Par.*, 1913, xlv, No. 33.

The operation of hydrocele. MÜLLER. *Zentralbl. f. Chir.*, 1913, xl, 1140.

Operation on the seminal vesicles. F. VÖLCKER. *Arch. f. klin. Chir.*, 1913, ci, 1088.

The remote effects of lesions of the prostate and deep urethra. THOMAS MCCRAE. *J. Am. M. Ass.*, 1913, lxi, 477. [675]

Diagnosis and treatment of early malignant disease of the prostate. H. KÜMMELL. *Tr. Internat. Cong. Med., Lond.*, 1913, Aug. [675]

A case of syphilis of the prostate gland. MAX HESSE. *Dermat. Wchnschr.*, 1913, lvi, 685.

Four cases of atrophy of the prostate gland. VICTOR CÆSAR. *Ztschr. f. Urol.*, 1913, vii, 615.

Present status of therapy in hypertrophy of the prostate gland. E. GRUNERT. *Ztschr. f. urol. Chir.*, 1913, i, 395.

Modifications of the theory of hypertrophy of the prostate. KIELLEUTHNER. *München. med. Wchnschr.*, 1913, lx, 1701.

What value is to be ascribed to Bottini's operation in the treatment of hypertrophy of the prostate gland. EUGEN REMETE. *Ztschr. f. urol. Chir.*, 1913, i, 387.

Prostatectomy. JOHN B. DEEVER. *Surg., Gynec. & Obst.*, 1913, xvii, 157. [676]

Prostatectomy. CIMINO. *Gazz. d. osp. e d. Clin., Milano*, 1913, xxxiv, No. 90.

Suprapubic prostatectomy. HUGH CABOT. *Surg., Gynec. & Obst.*, 1913, xvii, 213. [677]

Suprapubic prostatectomy by Morcellement. D. W. BASHAM. *Urol. & Cutan. Rev.*, 1913, xvi, 428.

A modified drainage for suprapubic prostatectomy. G. H. DAY. *N. Y. M. J.*, 1913, xcvi, 425. [677]

Miscellaneous

Urologic diagnosis. E. O. SMITH. *W. Va. M. J.*, 1913, viii, 37.

Serodiagnosis of gonorrhœal affections. FINKELSTEIN and GERCHOUNE. *Russk. j. cojnuch i vener. boliez., Moscow*, 1913, xxv, No. 4.

Erection in affections of the urinary tract. REGINALDO DOS SANTOS. *Med. contemp., Lisbon*, 1913, xxxi, 182.

Hetralin in infections of the uro-genital apparatus. VIKTOR DRUCKER. *Zentralbl. f. d. ges. Therap.*, 1913, xxxi, 393.

Infection of the urinary passages with colon bacillus. HESS. *Mitt. a. d. Grenzgeb. d. Med. u. Chir.*, 1913, xxvi, No. 1.

Preliminary report on the cutaneous deposit reaction of gonococci bacterin. N. E. ARONSTAM. *Urol. & Cutan. Rev.*, 1913, xvi, 410.

Morphology of a species of actinomyces of the male genital organs; treatment by vaccination. T. COHN. *Zentralbl. f. Bakteriöl., Parasitenk. u. Infektionskrankh.*, 1913, lxx, 290.

The importance of the germinal glands with respect to changes in sexual passion. G. SCHICKELE. *Ztschr. f. d. ges. exp. Med.*, 1913, i, 539.

Interesting malformations of the genital organs of man. ANSPRENGER. *München. med. Wchnschr.*, 1913, lx, No. 31.

Perineal suppuration in a typhoid carrier. LEVY. *Deutsche med. Wchnschr.*, 1913, xxxix, No. 31.

A combined cystoscope and evacuator. STANTON. *N. Y. M. J.*, 1913, xcvi, 265.

Conservative surgical treatment in urology. ARTHUR SCHWENK. *Ztschr. f. ärztl. Fortbild.*, 1913, x, 456.

Uterus with two Fallopian tubes and two testicles in the herniary sac in an individual with normally developed male external genitalia. PELLEGRINI. *Ginecologia, Milano*, 1913, x, No. 5.

SURGERY OF THE EYE AND EAR

Eye

Concerning certain ocular injuries and their treatment. G. E. DE SCHWEINITZ. *Therap. Gaz.*, 1913, xxix, 533.

Cases of injury to the lens and of foreign body in the eye. J. L. GIBSON. *Australas. M. Gaz.*, 1913, xxxiv, 167.

The present approved methods of treatment of obstructions to the lacrimo-nasal duct. E. N. ROBERTSON. *J. Kansas M. Soc.*, 1913, xiii, 279. [678]

Infarction of the posterior ciliary arteries. G. COATS. *Tr. Internat. Cong. Med.*, Lond., 1913, Aug. [678]

The results of the first hundred squint cases operated upon by the new method of subconjunctival reefing and advancement with lengthening of the antagonist where necessary. N. B. HARMAN. *Tr. Internat. Cong. Med.*, Lond., 1913, Aug. [678]

The cause and treatment of convergent squint. A. E. BULSON. *J. Indiana St. M. Ass.*, 1913, vi, 357. [679]

Sympathetic ophthalmia, with recovery. F. C. HEATH. *J. Indiana St. M. Ass.*, 1913, vi, 364. [679]

Unusual types of punctate cataract. T. B. HOLLOWAY. *Ophth. Rec.*, 1913, xxii, 407.

Diagnosis of sarcoma of the choroid; two cases of sarcoma with decreased intra-ocular pressure and one case of sarcoma of the eye. SELENKOWSKY. *Russk. Vrach*, St. Petersburg, 1913, xii, 553.

Sarcoma of the orbit following Mules's operation. D. WOOD. *Ophth. Rec.*, 1913, xxii, 422.

Melanotic sarcoma of the choroid coat of the eyeball; report of a case with apparent secondary involvement of retina. GEORGE P. KEIPER. *Ann. Ophth.*, 1913, xxi, 445.

A huge orbital osteoma. E. M. BLAKE. *Ophth. Rec.*, 1913, xxii, 419.

Glaucoma operation. P. SMITH. *Tr. Internat. Cong. Med.*, Lond., 1913, Aug. [679]

Observations on operations for glaucoma. DUNBAR ROY. *South. M. J.*, 1913, vi, 525. [679]

Dermoid of the eyes. KRAILSHEIMER. *Klin. Monatsbl. f. Augenh.*, 1913, ii, 796.

A case of bilateral orbital phlegmon following empyema of the frontal sinus and the ethmoidal cells, with special consideration of the pathological anatomical findings. S. TAKASHINA. *Klin. Monatsbl. f. Augenh.*, 1913, ii, 35.

Orbital cellulitis caused by staphylococci. S. B. MUNCASTER. *Ophth. Rec.*, 1913, xxii, 413.

Tamponade treatment of accessory sinuses for intra-ocular inflammations. WM. S. MANNING. *South. M. J.*, 1913, vi, 531.

The use of a conjunctival flap in the treatment of corneal infection and pannus. ELMER G. STARR. *Ann. Ophth.*, 1913, xxi, 471.

Ocular manifestations in nasal and aural diseases which probably indicate involvement of the sympathetic nervous system. W. H. HASKIN. *Ann. Otol., Rhinol. & Laryngol.*, 1913, xxii, 384.

Deformity of the skull with ocular symptoms. HARALD LARSEN. *Klin. Monatsbl. f. Augenh.*, 1913, ii, 145.

Ophthalmic progress in Egypt. A. F. MACCALLAN. *Lancet*, Lond., 1913, clxxxv, 470.

The importance of ophthalmological examination in immigrants. MARTIN COHEN. *Med. Rev. Rev.*, 1913, xxix, 484.

An address on the influence of the British Medical Association in establishing ophthalmology as a special science. THOMAS H. BICKERTON. *Brit. M. J.*, 1913, ii, 213.

A contribution to the history of the magnet as applied to ophthalmic surgery. H. G. SHIPMAN. *Cleveland M. J.*, 1913, xii, 550.

Ear

Conservatively treated peri-auricular, subperiosteal abscesses in scarlet fever. SÖRENSEN. *Therap. Monatschr.*, 1913, xxvii, 568.

Abscess of frontal lobe of the brain, of otitic origin, with exhibition of specimens. T. P. BERENS. *Ann. Otol., Rhinol. & Laryngol.*, 1913, xxii, 433.

Danger signals in suppuration of the middle ear. J. HOLLINGER. *Illinois M. J.*, 1913, xxiv, 107.

Peri-sinus abscess as a complication to acute middle ear suppuration. JAMES HARPER. *Practitioner*, Lond., 1913, xci, 213.

Treatment of chronic suppurative otitis. FERNANDEZ SECO. *Rev. de med. y cir. pract.*, Madrid, 1913, xxxvii, No. 1279.

Phylacogen in middle ear abscess. S. G. DABNEY. *Louisville Month. J.*, 1913, xx, 74.

Intracranial division of the auditory nerve for persistent tinnitus. CHARLES FRAZIER. *J. Am. M. Ass.*, 1913, lxi, 327.

The diagnosis of rupture into the lateral ventricle and of acute internal meningitis. E. RUTTIN. *Laryngoscope*, 1913, xxiii, 819.

Brief consideration of certain recent views regarding otosclerosis. T. HARRIS. *Laryngoscope*, 1913, xxiii, 801.

Abscess of the vestibule of dental origin. FARGIN-FAYOLLE. *Paris méd.*, 1913, No. 35.

Two cases of loss of caloric vestibule reaction, with operative findings. E. B. DENCH. *Tr. Internat. Cong. Med.*, Lond., 1913, Aug. [679]

Report of twenty cases of inflammatory affections of the labyrinth. PHILLIPS, FOWLER, KOPENTZKY and SHARP. *N. Y. M. J.*, 1913, xcvi, 209.

When to operate on the labyrinth in labyrinth infection secondary to purulent otitis media. G. E. SHAMBAUGH. *Ann. Otol., Rhinol. & Laryngol.*, 1913, xxii, 303. [680]

The technique of the labyrinth operation. E. B. DENCH. *Laryngoscope*, 1913, 814.

Trephining of the labyrinth for vertigo and buzzing in the ears. R. BOTEY. *Tr. Internat. Cong. Med.*, Lond., 1913, Aug. [680]

Anatomical preparations to illustrate trephining of labyrinth. R. BOTEY. *Tr. Internat. Cong. Med.*, Lond., 1913, Aug. [681]

The report of a case of paracoustic vertigo and nystagmus cured by operation on the labyrinth. J. R. PAGE. *Ann. Otol., Rhinol. & Laryngol.*, 1913, xxii, 321.

Diagnosis and treatment of acute mastoiditis. GEORGE H. MATHEWSON. *Canad. M. Ass. J.*, 1913, iii, 672.

Mastoiditis; diagnosis; non-surgical treatment and indications for operation. C. A. HARKNESS. *Clinique*, 1913, xxxiv, 427.

Surgical anatomy of the mastoid. J. MOURET. *Tr. Internat. Cong. Med.*, Lond., 1913, Aug. [681]

The combined laboratory and X-ray indications for the mastoid operation. G. S. DIXON. *Ann. Otol., Rhinol. & Laryngol.*, 1913, xxii, 369.

Clinical indications for the mastoid operation. W. S. BRYANT. *Ann. Otol., Rhinol. & Laryngol.*, 1913, xxii, 482.

The radical mastoid operation in children. D. G. YATES. *Am. J. Surg.*, 1913, xxvii, 293.

Management of mastoid wounds. W. S. BRYANT. Tr. Internat. Cong. Med., Lond., 1913, Aug. [681]

Dangers of ligating the jugular vein in otology and possibility of preventing them. KRAMPITZ. Internat. Zentralbl. f. Ohrenheilk. u. Rhino-Laryngol., 1913, xi, 161. [682]

Pharyngeal drainage of cranial suppurations of otogenous origin. P. JACQUES. Tr. Internat. Cong. Med., Lond., 1913, Aug. [682]

Illuminated ear speculum. FREDERICK A. KIEHLE. J. Am. M. Ass., 1913, li, 491.

SURGERY OF THE NOSE, THROAT, AND MOUTH

The correction of nasal deformities, particularly lateral deflections and depressions with obstructing deviations of the septum. G. M. MARSHALL. Penn. M. J., 1913, xvi, 853.

Odd cases of nasal deflection with suggestions as to treatment of nasal adhesions. OTIS H. McCLAY. Illinois M. J., 1913, xxiv, 129.

The septum nasi and its abnormalities. FRANCIS MUECKE. Practitioner, Lond., 1913, xci, 202.

Pathology and diagnosis of malignant diseases of the nose and nasal-pharynx. H. MARSCHIK. Tr. Internat. Cong. Med., Lond., 1913, Aug. [683]

Unusual bullet wound of frontal sinus. KENNETH FULKLEY. J. Am. M. Ass., 1913, li, 412.

Post-operative dry rhinitis and its prevention; a contribution on the prevention of post-operative cerebral complications of nasal origin. RHESE. Ztschr. f. Ohrenh. u. f. d. Krankh. d. Luftw., 1913, lxix, No. 1.

Hypertrophic rhinitis and hyperostosis of the superior maxilla. T. B. LAYTON. Guy's Hosp. Gaz., 1913, xxvii, 343.

Atrophic rhinitis with ozena — its etiology and surgical treatment. F. P. EMERSON. Ann. Otol., Rhinol. & Laryngol., 1913, xxii, 333.

Tumors of the septum. R. H. JOHNSTON. Laryngoscope, 1913, xxiii, 834.

Temporary resection of superior maxilla for ossifying chondroma of nasopharynx. KOCHER and HORAND. Lyon chir., 1913, x, 135. [683]

Radium treatment of rhinophyma. DEGRAIS. Strahlentherapie, 1913, iii, No. 2.

Polypi. V. H. WYATT WINGRAVE. Practitioner, Lond., 1913, xci, 192.

Two cases of nasopharyngeal polyp; some points on operative technique. DENIS and VACHER. Rev. hebdomadaire de laryngol., d'otol. et de rhinol., Bordeaux, 1913, No. 31.

Two cases of nasopharyngeal polypus in young persons mistaken and operated on for adenoids. BUTT. Penn. M. J., 1913, xvi, 861.

Intranasal treatment of Meckel's ganglion. E. M. HOLMES. Ann. Otol., Rhinol. & Laryngol., 1913, xxii, 350.

Some attempts at the intranasal transplantation of nasal tissues. S. IGLAUER. Ann. Otol., Rhinol. & Laryngol., 1913, xxii, 308. [683]

Intranasal opening of the superior maxillary sinus. OSWALD LEVINSTEIN. Ztschr. f. Laryngol., Rhinol. u. i. Grenzgeb., 1913, vi, 419.

A case of purulent meningitis after an intranasal intervention. REISCHIG. Ztschr. f. Ohrenh. u. f. d. Krankh. d. Luftw., 1913, lxix, No. 1.

Conservatism versus radicalism in nasal surgery. NEWTON BOWMAN. Tex. Med. News, 1913, xxii, 1506.

Adenoids and enlarged tonsils. T. M. MARTIN. Clin. J., 1913, xlii, 329.

Removal of adenoids by direct inspection. J. C. BECK. Ann. Otol., Rhinol. & Laryngol., 1913, xxii, 273. [683]

The removal of adenoids and tonsils in children. A. COOLIDGE and F. E. GARLAND. Boston M. & S. J., 1913, clxix, 306.

The enucleation of tonsils and removal of adenoids. H. BULLOCK. Australas. M. Gaz., 1913, xxxiv, 197.

Gangrenous tonsil. U. S. BIRD. South. M. J., 1913, vi, 539.

The significance of plasma cells in the tonsils. GORDON J. WILSON. J. Am. M. Ass., 1913, li, 345.

The symptoms of pathological lingual tonsil and its treatment. HAROLD HAYS. Am. J. Surg., 1913, xxvii, 309.

Report of a case of phlegmon starting as a peri-tonsillar abscess and extending downward as far as the second ring of the trachea. G. L. RICHARDS. Laryngoscope, 1913, xxiii, 835.

Is the present immolation of the tonsil justifiable? J. A. WHITE. Va. M. Semi-Month., 1913, xviii, 237.

Treatment of the pharyngeal tonsil. R. GOLDMANN. Monatschr. f. Ohrenh. u. Laryngo-Rhinol., 1913, xlvii, 1029.

Simplified technique for the removal of the faucial tonsils. L. F. LONG. Laryngoscope, 1913, xxiii, 838.

Indications for and relative value of tonsillotomy. J. L. GOODALE. Tr. Internat. Cong. Med., Lond., 1913, Aug. [684]

Results in a series of cases of tonsillectomy at the Massachusetts General Hospital, three to four years after operation. J. P. CLARK. Ann. Otol., Rhinol. & Laryngol., 1913, xxii, 421.

The pathology of the various acute inflammations of the throat and neck including acute oedema, phlegmon and erysipelas and angina lucovici but excluding diphtheria. P. R. W. DE SANTI. Tr. Internat. Cong. Med., Lond., Aug. [684]

Safety pin removed from the larynx of a child by direct laryngoscopy. HARMON SMITH. N. Y. M. J., 1913, xcvi, 313.

The normal and the diseased larynx of the living in the X-ray picture. THOST. Ztschr. f. Laryngol., Rhinol. u. i. Grenzgeb., 1913, vi, 501.

Chronic stenosis of the larynx and trachea. C. A. LEAVY. Laryngoscope, 1913, xxiii, 841.

The treatment of diphtheritic stenoses; data furnished by the Wladimir Children's Hospital in Moscow (for the years 1897-1911). N. U. USSPENSKI. Paediatrica, 1913, No. 4, 257.

Remarks and results on twenty cases of laryngeal diphtheria requiring tracheotomy. C. E. PURCELL. Laryngoscope, 1913, xxiii, 849.

Dysphagia in tuberculosis of the larynx. RÉTHI. Ztschr. f. Laryngol., Rhinol. u. i. Grenzgeb., 1913, vi, 512.

Notes on the tubercular laryngitis. D. A. VANDERHOOF. J. Mo. St. M. Ass., 1913, x, 60.

Effect of pneumothorax treatment on laryngeal tuberculosis. E. WINCKLER. *Ztschr. f. Laryngol., Rhinol. u. i. Grenzgeb.*, 1913, vi, 293.

Metastatic abscesses in the musculature of the larynx. R. IMHOFER. *Ztschr. f. Laryngol., Rhinol. u. i. Grenzgeb.*, 1913, vi, 281.

A report of a case of carcinoma of the larynx, with complete laryngectomy, and two cases of papilloma of the larynx, with thyrotomy. A. J. LORIE. *Physician & Surg.*, 1913, xxxv, 358.

Acute primary infectious oedema of the larynx and its microbiological relationship. BAR. *Ann. d. mal. de l'oreille, du larynx, du nez, et du pharynx*, Par., 1913, xxxix, No. 7.

Suspension laryngoscopy with demonstration of method. W. FREUDENTHAL. *Ann. Otol., Rhinol. & Laryngol.*, 1913, xxii, 464.

The best method for extirpating the larynx. R. BOTEV. *Tr. Internat. Cong. Med., Lond.*, 1913, Aug. [685]

Complications in the cure of a case of total extirpation of the larynx and the pharynx for carcinoma. HOLSCHER. *Ztschr. f. Laryngol., Rhinol. u. i. Grenzgeb.*, 1913, vi, 512.

Laryngectomy subsequent to tracheotomy for epithelioma of the larynx. DAN MCKENZIE. *Lancet*, Lond., 1913, clxxxv, 287.

Intubation. R. W. BEMIS. *Penn. M. J.*, 1913, xvi, 859.

Endothelioma or epithelioma of the epiglottis. SSAMOYLENKO. *Beitr. z. Anat., Physiol., Path. u. Therap. d. Ohres, d. Nase u. d. Halses*, 1913, vi, Nos. 4-6.

Acute retropharyngeal abscess. ALEXANDER and MONTAGUE. *N. Y. M. J.*, 1913, xcvi, 224.

Primary malignant growths in the pharynx. E. OPPENKOFER. *Arch. f. Laryngol. u. Rhinol.*, 1913, xxvii, 526.

The physiology of the mechanism of deglutition from röntgenocinematographic pictures. L. KUPFERLE. *Arch. f. d. ges. Physiol.*, 1913, xlii, 579.

A brush-shaped kerato-epithelioma of the mucous membrane of the cheek, being a contribution to the etiology and histopathogenesis of cornu cutaneum. GEORGE KONJETZNY. *Beitr. z. path. Anat. u. z. allg. Path.*, 1913, lvii, 57.

Authoritative diagnosis of gonorrhoeal stomatitis. JOHN BETHUNE STEIN. *Med. Rec.*, 1913, lxxxiv, 242.

Ademantinomata. JOHANNES IPSEN. *Hosp.-Tid., Kjøbenhavn.*, 1913, lvi, 898.

Solitary cysticercous of the tongue. R. HAHN. *Arch. ital. di otol., rhinol. e. laringol.*, 1913, xxiv, 272.

Curability of cancer of the tongue. BAUDET. *Gaz. d. Hôp., Par.*, 1913, lxxxvi, No. 89.

Ethyl chloride anesthesia in operative dentistry. A. KNEUCKER. *Wien. klin. Wchnschr.*, 1913, xxvi, 1277.

Allypin in dentistry. KRAUSE. *Deutsche zahnärztl. Wchnschr.*, 1913, xvi, 585.
